It is seen that methionine methyl serves as a precursor of both the methylenedioxy and N-methyl groups of the alkaloid. Formate also contributes activity to the molecule, although to a considerably less extent than methionine. Formate serves as a precursor of labile methyl in the barley and tobacco plants[1,2], but it could not be shown with certainty that it was a precursor in the present case. The radioactivity in the alkaloid from the formate experiment was so low that significant specific activities for the degradation products could not be obtained. Nevertheless, the results indicate that the methylenedioxy groups arise from the oxidation of an O-methyl group followed by ring closure on an adjacent hydroxyl rather than a formylation followed by reduction and ring closure. If the reverse were true, one would expect the alkaloid from the formate run to be labelled to at least as great an extent as the alkaloid from the methionine run. This follows from the fact that the level of activity fed in the formate experiment was four times that in the methionine experiment. If formate was a more direct precursor of the methylenedioxy groups than was methionine methyl, this high activity which was fed, coupled with the fact that the methylenedioxy groups contribute one-third of the total activity in the methionine run, would lead one to expect a higher level of activity in the formate experiment.

The fact that choline methyl does not contribute activity is not surprising. It has been previously shown, in the case of both barley and *Ricinus* plants, that choline methyl contributes neither to the 'labile methyl' nor 'formate' pools of these plants. The *Dicentra* plants seem to follow the same pattern.

An inspection of the table shows that if one subtracts the activity in the methylenedioxy groups and the N-methyl group from the total activity in the molecule, one is left with a residual activity approximately twice that in the N-methyl group. An inspection of the structure of protopine shows that it could have originated from two dihydroxyphenylalanine residues plus the carbon atom in the dotted circle. It is tempting to postulate that the residual activity is in this carbon atom, which had its biogenesis in the 'formate' pool of the plant. It has been shown that this 'formate' pool is concerned with biosyntheses involving single carbon atoms[9].

We wish to thank Dr. R. H. F. Manske for the plant material used in these experiments and for providing much useful advice. We also thank the Rockefeller Foundation for financial support for this work.

## Relative Reactivities of the Olefinic and Cyano Links of Acrylonitrile in the Diels–Alder Reaction

THE Diels–Alder reaction, in which a stable six-membered ring is formed by 1,4-addition of an unsaturated linkage to a diene, has wide synthetic application. The role of the olefinic group as a dienophile is well known[1]. More recently, the addition of the cyano group to dienes with the formation of pyridinic products has been reported[2]. Acrylonitrile presents an interesting example in which the groups (C = C) and (C ≡ N), both dienophilic, are present. The present communication reports the results of a study on the reactions of acrylonitrile with butadiene. The relative reactivity of these two links of acrylonitrile in this reaction can be predicted from thermodynamic and kinetic considerations. The free energy changes at 700° K. for the formation of cyano*cyclo*hexene and vinylpyridine are −21 and −14 kcal./mol. respectively. These results are qualitative, since the data for the cyclic products were estimated by the method of group increments[3]; but they show that the two reactions are both thermodynamically feasible in this temperature-range. The ultimate yields are a concern of reaction kinetics. The relative rates of these two reactions, assuming the cyclization to be the rate-controlling step, were calculated from the expression:

$$k_a/k_b = \exp( (S_a^{\ddagger} - S_b^{\ddagger})/R - (E_a - E_b)/RT),$$

using the kinetic data of related high-temperature Diels–Alder associations. From a consideration of the activation energies of the reactions of acrolein[4] and cyanogen[5] respectively with butadiene, a minimum value of − 11·9 kcal. was obtained for $(E_a - E_b)$. The magnitude of $(S_a^{\ddagger} - S_b^{\ddagger})$ for the activated complexes was taken as approximately − 1·1 e.u. from the difference in entropy of 3-cyano*cyclo*hexene and 2-vinyldihydropyridine. Accordingly, at 400° C. in the homogeneous gas phase, it is predicted from these data that the formation of cyano*cyclo*hexene is 5,800 times more rapid than the formation of vinylpyridine.

The experimental study has shown that in the homogeneous reactions at about 400° C., only cyano*cyclo*hexene is found as product of the addition of acrylonitrile to butadiene. This is in accord with the analysis above, that is, very little, if any, vinylpyridine would be formed. In view of the favourable free-energy changes, the reactions were investigated in the presence of a catalyst. With chromium oxide – aluminium oxide as the catalyst system, acrylonitrile reacts by the (C=C) and (C≡N) bonds as predicted from the thermodynamic considerations. Taking yields as a measure of the relative rates of reaction, since both groups are competing for the diene, the reactivity of the (C=C) group is fifteen times greater than the (C≡N) group in the catalysed reactions. A summary of the experimental results is given in the accompanying table.

| Experimental reaction conditions | | | | Yields (mol. per cent) | |
|---|---|---|---|---|---|
| Catalyst | Time | Temp (° C.) | Press (atm.) | Cyano-*cyclo*hexene | Vinyl-pyridine |
| — | 14 hr. | 160 | 1 | 80 | — |
| — | 6 sec. | 390 | 1 | 77 | — |
| 4% $Cr_2O_3$ on alumina | 4 sec. | 480 | 1 | 28·0 | 1·8 |

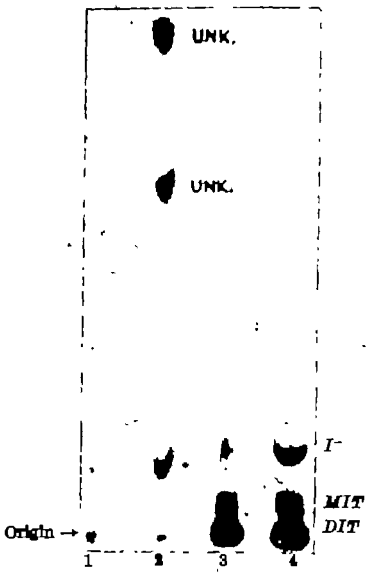
## Artefacts produced from 3-Iodo-Tyrosine and 3 : 5-Di-iodo-Tyrosine by Heating with Alkali

DURING a study[1] of the hydrolysis of native hog thyroglobulin labelled with iodine-131, by a purified protease isolated from hog thyroid glands, fractions eluted from paper chromatograms of the enzyme fission products were treated with 2*N* sodium hydroxide at 105° for 16 hr. Control aliquots were allowed to stand for the same time at 0°. On application of *n*-butanol extracts of the heated and control samples to paper and development of the chromatograms with *n*-butanol – *n*-pentanol – ammonia[2] as solvent, unexpected radioactive spots of high $R_F$ (at 0·52 and 0·68) were observed with the heated samples. Since the original eluates were found to contain free mono- and di-iodo-tyrosine and thyroxine, the action of alkali on purified samples of the iodo-amino-acids was examined.

Labelled iodo-tyrosines and thyroxine were obtained by the micro-iodination method of Lemmon, Tarpey and Scott[3] from L-tyrosine and 3 : 5-di-iodo-DL-thyronine respectively. The products were separated from unreacted iodide and other impurities by paper chromatography. *n*-Butanol – *n*-pentanol – ammonia was found best for the purification of thyroxine, and *n*-pentanol – propionic acid – water (20 : 3 : 10) for mono- and di-iodo-tyrosine, which were readily separated in this system from each other and from iodide. Incidentally, this acidic solvent system may also be used to separate thyroxine, which has an $R_F$ value of 0·80 compared with 0·28, 0·51 and 0·04 for mono-iodo-tyrosine, di-iodo-tyrosine and iodide respectively on Whatman No. 1 paper.

When labelled thyroxine was heated under the above conditions and the product extracted into butanol, a loss of approximately 10 per cent occurred as measured by iodine-131 activity of the extract, but no artefacts were detected. In the case of di-iodo-tyrosine, however, there was a four- to eight-fold increase in activity of the butanol-soluble fraction compared with the corresponding extract obtained from a control solution allowed to stand at 0°. Moreover, application of the butanol extract of the heated sample to paper and development with butanol – pentanol – ammonia gave radioactive spots at $R_F$ 0·52 and 0·72 corresponding to those detected in the hydrolysates from the enzyme fission products. (On the same chromatogram, carrier mono- and



Radioautogram of chromatogram of butanol extracts, washed with water, of an alkali-treated (2*N* sodium hydroxide, 16 hr.) preparation of iodine-131 labelled 3-iodo- and 3 . 5-di-iodo-L-tyrosine 1 and 2: direct extracts of assay (105°) and control (0°). 3 and 4: extracts of assay and control after adjustment of *p*H to 3·5 with hydrochloric acid. *MIT*, *DIT*: mono- and di-iodo-tyrosine. I⁻: iodide. UNK: unknown. Solvent · butanol – pentanol – ammonia. Whatman No. 3 paper

di-iodo-tyrosine and thyroxine were made visible by ninhydrin at $R_F$ 0·03, 0·01 and 0·22 respectively.)

The same radioactive artefacts were produced when labelled di-iodo-tyrosine was heated with alkali in the presence of carrier, also from mono-iodo-tyrosine (but to a lesser extent) and from a mixture of labelled mono- and di-iodo-tyrosine. The accompanying radioautogram is of a chromatogram obtained from butanolic extracts of the alkaline solution (before and after adjusting to *p*H 3·5) resulting from an experiment in which a mixture of the iodo-tyrosines was used. An unheated control was similarly extracted and applied.

So far as quantitative studies have been made, it appears that under the above conditions only about 5 per cent of the activity of labelled di-iodo-tyrosine is transferred to the artefact fraction. Thus, in the assay of thyroglobulin for its thyroxine content in which a butanol extract of the hydrolysate is used, the error would be almost negligible; however, with artificial thyroproteins, owing to the usually higher iodo-tyrosine/thyroxine ratio[4], allowance might have to be made. Friedberg and Reineke have reported recently[5] on the presence of significant amounts of iodine-containing substances other than thyroxine in washed butanol extracts of iodo-casein hydrolysates, but no details are given. It is possible that these substances arise in part from iodo-tyrosines as suggested by the present investigation.

## Latent Carcinogenic Action of Beta-Irradiation on Mouse Epidermis

A SINGLE application of a carcinogenic hydrocarbon, in itself insufficient to cause tumours, can bring about a change in mouse skin enabling subsequent applications of the non-carcinogenic substance croton oil to result in the formation of papillomas and carcinomas[1]. It seemed of interest to inquire whether a 'latent' tumour change similar to that produced by the hydrocarbon could be induced in mouse skin by the local application of beta-rays in a single, subcarcinogenic dose.

A total of eighty-six female Swiss mice was used in this first exploratory experiment. As in previous investigations of chemical skin carcinogenesis,[1] the interscapular region was chosen for exposure. Thallium-204 was selected as a source of moderately energetic beta-rays, in order to localize the radiation injury to a relatively small volume of skin. The isotope is produced by neutron bombardment of stable thallium-203 by the reaction (*n*γ). Thallium-204 decays to stable lead-204 with the emission of a beta-particle that has a maximum energy of 0·78 MeV.; its half-life is approximately three years. The thallium was supplied by the Oak Ridge National Laboratory of the U.S. Atomic Energy Commission as thallium nitrate with a specific activity of 0·042 mC./mgm. After purification and repeated precipitation, the thallium nitrate was filtered on paper disks 6 mm. in diameter.

The paper disks were then mounted on 'Lucite' holders and fastened to them with a single layer of Scotch tape. The transparent tape absorbed not more than 10 per cent of the radiation. The dosage rate at the surface of the plaques was calculated, since no appropriate instruments for direct measurements were available. The calculated dose was 870 rep./hr. Two of the plaques were assayed in the Radio-Isotope Control Department of the Oak Ridge National Laboratory through the courtesy of J. H. Gillette, who determined a value of about 800 rep./hr.

For exposure, the animals were placed in tightly fitting cylindrical plastic tubes. The interscapular region of the skin was exposed through a square window in the centre of the tube, into which was fitted the 'Lucite' holder with the radioactive plaque. The animals were held in this position by corks at either end of the tube. The plaque could be manipulated so as to be in direct contact with the skin. All animals were uniformly exposed for one hour, receiving approximately 800 rep. The beta-rays of this energy have a penetration in tissue of 2·5 mm. as a maximum, and the greatest damage, therefore, was done to the epidermis and its appendages. The croton oil was applied twice weekly as a 5 per cent solution in mineral oil (croton oil was obtained from Messrs. Boots, Nottingham, and the mineral oil, 'Superla 34', from the Standard Oil Company of Indiana). Croton oil treatment of the irradiated animals was begun one week following the radiation exposure. It is still continuing to-day with the surviving animals.

The radiation reaction was very mild in the group receiving radiation alone. There was slight erythema with minimal epilation two to three weeks after exposure. The hair grew again, and no skin abnormalities have been observed to date in these animals. In the second group of animals, receiving irradiation followed by croton oil, six animals have developed tumours

| Group | No. of animals | Irradiation (rep.) | Croton oil | Animals with tumours | Total No. of tumours | Survivors (8 months) |
|---|---|---|---|---|---|---|
| I | 26 | 800 | 0 | 0 | 0 | 21 |
| II | 30 | 800 | twice weekly | 6 | 13 | 17 |
| III | 30 | 0 | twice weekly | 0 | 0 | 20 |

so far, with an average of two tumours per animal. The first tumour was recorded six weeks after painting was begun. There have been no regressions and no malignancies. Some of the tumours were quite large. The average latent period has been 3·5 months. The animals receiving the croton oil alone showed the typical lesions of the skin associated with this treatment. The results are briefly summarized in the accompanying table.

While the total number of animals with tumours may appear small, it should be remembered that the dosages employed in this first experiment were deliberately made small. They were shown to be non-carcinogenic in the irradiated control animals, none of which has developed tumours so far. They were also considerably smaller than those reported to have been carcinogenic by Raper, Henshaw and Snider[2], who with total body beta-irradiation from phosphorus plaques described skin tumours with 3,000–4,500 rep., many of which regressed later on. Glücksmann has stated recently that he has been unable to produce skin tumours in mice with less than 8,000 rep.[3].

This work was supported in part by a research contract from the United States Atomic Energy Commission and in part by a research grant from the National Cancer Institute of the National Institutes of Health, Public Health Service.

## Occurrence in Plants Infected with Tobacco Mosaic Virus of a Crystallizable Antigen devoid of Ribonucleic Acid

PURIFIED preparations of tobacco mosaic virus have often been shown to be heterogeneous, some of the separated fractions being non-infective[1]. The latter are to some extent comparable with the 'soluble antigens' of animal viruses and have a bearing on the study of the mechanism of virus multiplication[2]. The following observations have been made on such fractions.

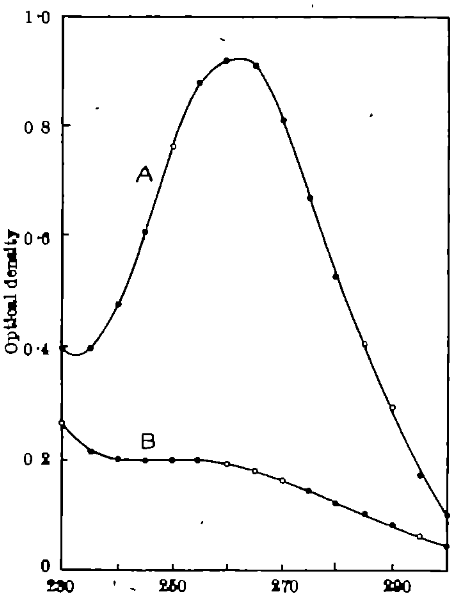
Extracts of the younger leaves of tobacco plants infected two months beforehand were centrifuged for 10–60 min. in a Spinco model *L* ultracentrifuge at 28,000 r.p.m. An aliquot of the supernatant obtained after 60 min. was centrifuged at 40,000 r.p.m. for a further 60 min. Infectivity of the supernatant liquids was compared with that of the initial extract by applying them and several dilutions of the latter to the two halves of leaves of *Nicotiana glutinosa*.

At the same time a sufficient amount of antiserum obtained by injection of tobacco mosaic virus into rabbits was added to equal volumes of the different supernatants, so that the antibody was in slight excess. Controls were prepared from normal serum and extracts of normal plants. The nitrogen content of the precipitates was determined. Results of a typical experiment are given in the accompanying table. It will be seen that centrifugation leads to a considerably more rapid decrease in the number of infective particles than in the total amount of material capable of reacting with the antibody, so that the very slightly infective supernatant obtained at 40,000 r.p.m. contains an important fraction of the total antigen present in the initial extract. Thus, as well as the infective particles with a high sedimentation-rate, the extracts appear to contain a large quantity of non-infective constituents which are immunologically similar, but characterized by a lower sedimentation-rate.

| Duration of centrifugation (min.) | Speed (r.p.m.) | Concentration of infective virus particles (arbitrary units) | Protein N antibody + antigen (μgm.) |
|---|---|---|---|
| 10 | 10,000 | 2,750 | 1,093 |
| 60 | 28,000 | 35 | 308 |
| 60 | 40,000 | 1 | 243 |

On the basis of these preliminary results, one can estimate the sedimentation-rate of the non-infective material remaining in the supernatant after 1 hr. at 40,000 r.p.m. to be at the most 1/30 of that of the infective particles. We attempted to isolate it from the centrifuged extract by the following procedure repeated three times: removal of proteins precipitating at $pH$ 4·7; precipitation at $pH$ 3·8 of proteins remaining in solution, followed by the taking up into solution of this material at $pH$ 7·0. The final precipitate at $pH$ 3·8 is exclusively formed of paracrystalline needles identical with those of the virus. The amount of protein isolated was equal to 1/16–1/20 of the infective virus obtained after 60 min. centrifugation at 28,000 r.p.m. This fraction has the following characteristics. It is non-infective. Like tobacco mosaic virus, it is largely precipitated by the antibody of an antiserum obtained by injection of tobacco mosaic virus, but the precipitate is finely granular instead of flocculent. Except in this last character, no other immunological difference has been found between the two substances. As regards the chemical properties, the non-infective protein contains no ribose (negative orcinol test) and no purine or pyrimidine bases (no characteristic ultra-violet absorption of a 10 per cent perchloric acid extract). It does not contain a measurable amount of ribonucleic acid (see graph).

The solution of this protein contains particles visible in the electron microscope and a quarter to an eighth of the length of the tobacco mosaic virus and comparable thickness. These dimensions do not agree with the fact that this protein remains in the supernatant of the initial extract after 60 min. centrifugation at 40,000 r.p.m.; it would thus have a sedimentation-rate much smaller than the one



Absorption spectra of 10 per cent perchloric acid extracts of equal quantities of virus (*A*) and crystallized non-infective material (*B*)

expected for the visible particles. Isolation processes, however, may be accompanied by partial aggregation of initially smaller units. On the whole, this fraction is strikingly similar to the non-infective protein which accompanies the turnip yellow mosaic virus[3]. It is possible that the presence of similar proteins is a general characteristic of virus diseases in plants. A more extensive study of these proteins will be necessary to give us a clue as to their origin and possible significance for virus multiplication.

We are indebted to Mr. F. C. Bawden for the gift of the purified virus employed and seeds of *Nicotiana tabacum* var. White Burley.

## Effects of Trichloroacetic Acid on the Extension Growth of Root and Shoot Segments of *Pisum sativum*

It has been established that the sodium or ammonium salts of trichloroacetic acid can be employed for the control of graminaceous weeds in a variety of crops, but little is yet known concerning the physiological effects and the mode of action. Veldstra[1] has shown that, at a concentration of $5 \times 10^{-3}$ *M*, trichloroacetic acid causes curvature in the split pea test, but doubts whether the operative mechanism is similar to that of recognized growth regulators. On the other hand, Holly, a member of this Unit, observed in East African field trials in 1950 that trichloroacetic acid caused ear deformities in *Dactyloctenium giganteum* and *Panicum maximum* which were very similar to those produced in cereals by 2 : 4 dichlorophenoxyacetic acid. Again, in the laboratory, the morphological effects induced in *Lemna minor* were similar to those caused by the dichlorophenoxyacetic acid.

In the course of a general investigation of the physiological effects of trichloroacetic acid a detailed study has been made of the changes in the extension growth of root and shoot segments of *Pisum sativum* (var. Alaska) induced by this acid either alone or in combination with 2 : 4 dichlorophenoxyacetic acid. The techniques employed are those described by Brown and Sutcliffe[2] for the root segments and Thimann and Bonner[3] for the shoot segments.

The changes in root elongation caused by varyin concentrations of trichloroacetic acid are shown i Fig. 1, and it is to be noted that the relationshi is of a most unusual type. At exceedingly low con centrations ($10^{-11}$ *M*) there is some inhibition whic reaches a maximum at *c.* $10^{-9}$ *M*. At higher concentrations there is a reversal in trend such tha growth is not affected at $10^{-4}$ *M*, while betwee $10^{-4}$ *M* and $3 \times 10^{-3}$ *M* the rate of elongation i progressively increased. It is not until a concentratio of no less than $10^{-2}$ *M* is reached that extensio growth is again inhibited. A possible explanation i that there are three independent actions involve an inhibitory effect at low doses, which becom masked by an independent stimulatory effect intermediate trichloroacetic acid concentrations, a a final inhibition probably associated with gro damage to the tissue.

In contrast to the results for root segments, when similar measurements are made on intact roots, as in the cress-root method devised by Audus[4], there is no evidence of accelerated growth and the reduction occurs at a concentration of about $10^{-3}$ *M*. The behaviour of the shoot segments is similar to that of the intact roots, except that there is a more progressive reduction in elongation occurring over the range $10^{-4}$–$10^{-3}$ *M*.

When shoot and root segments are treated with trichloroacetic acid and 2 : 4 dichlorophenoxyacetic acid alone and in combination, statistical analyses show that there are definite and significant interactions. Because of the complexity of the dose

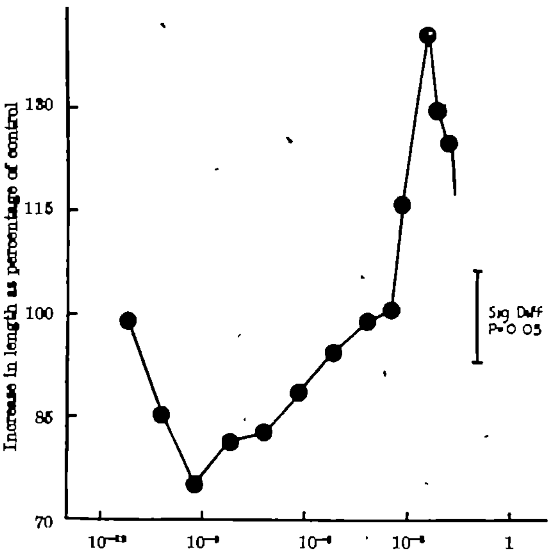

Fig. 1. Elongation growth of pea root segments grown for 24 hr. in nutrient solutions containing varying amounts of trichloroacetic acid

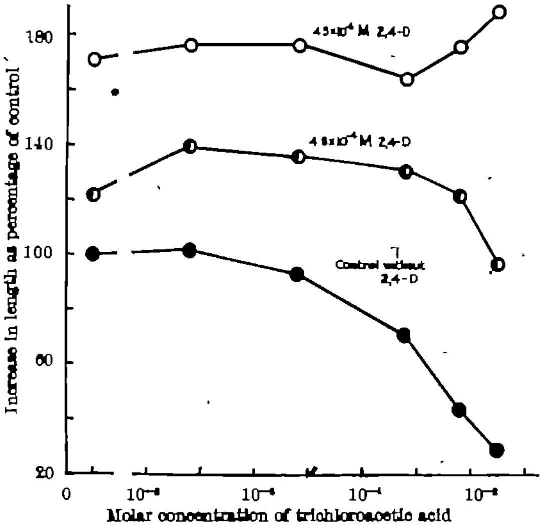

Fig. 2. Elongation growth of pea shoot segments kept for 24 hr. in solutions containing varying amounts of trichloroacetic acid, and 2 : 4 dichlorophenoxyacetic acid

response curves (see Fig. 1) the interpretation of the interactions is complex and a detailed discussion will be published elsewhere, but one aspect is illustrated in Fig. 2. When 2 : 4 dichlorophenoxyacetic acid is added at concentrations of either $4·5 \times 10^{-6}$ *M* or $4·5 \times 10^{-4}$ *M*, then the normal inhibitory effects of increasing concentrations of trichloroacetic acid are largely eliminated. Indeed it is evident that there are combinations where the increase in extension growth brought about by the growth regulator alone will be accelerated by the addition of trichloroacetic acid at a concentration which by itself would have been markedly inhibitory.

It is suggested that the phytotoxic properties of trichloroacetic acid may be related to the auxin status of the plant and that herbicides consisting of mixtures of trichloroacetic acid and 2 : 4 dichlorophenoxyacetic acid may have definite disadvantages.

## A Cladoceran from the Plankton as a Possible Indicator for the Presence of the Nile Flood off the Israeli Coast

DURING the examination of the plankton collected in the course of the monthly cruise off the Israeli coast in September 1951 an unusual abundance of a cladoceran, identified as *Podon polyphemoides* (Leuck.), was observed in some of the samples. The organism was found to be present along the coast from Askalon in the south to Athlit in the north, being most abundant at a depth of 10 fathoms, its incidence gradually decreasing towards the 75-fathom depth-line.

The relative scarcity of Cladocera in the marine plankton of this part of the Mediterranean in the preceding and following months suggests that the sudden mass occurrence of *Podon polyphemoides* in the plankton of the coastal waters of Israel at this time of the year is due to a current of water flowing along the coast in a northerly direction. This current is induced by the opening of the dams in the Nile delta a few weeks earlier, thus releasing a powerful flow of fresh water into the sea[1].

A striking correlation has been found to exist between the occurrence of *Podon polyphemoides* and a substantial drop in salinity caused by the Nile flood by the time it reaches the stations where sampling took place along the coast.

The organism is mentioned by previous investigators as occurring occasionally in the plankton of the Suez Canal[2] as well as in the plankton of the eastern and western harbours of Alexandria in the month of March[3]. Steuer[4], however, failed to find *Podon* in the plankton while working in that region, but mentioned in another place the ability of the organism to live both in fresh and salt water[5]. The euryhaline and neritic characteristics of this organism have also been stressed by Ramner[6].

Specimens of this cladoceran were sent to Prof. V. Brehm, who kindly confirmed my identification.

It is to be assumed that the mass occurrence of *Podon polyphemoides* along the Israeli coast during the month of September is connected with the appearance of the Nile flood waters in this region, and may serve as a possible indicator for the detection of the Nile flood in this part of the Mediterranean and the direction followed by the current in its northerly course. Work on this subject is continuing.

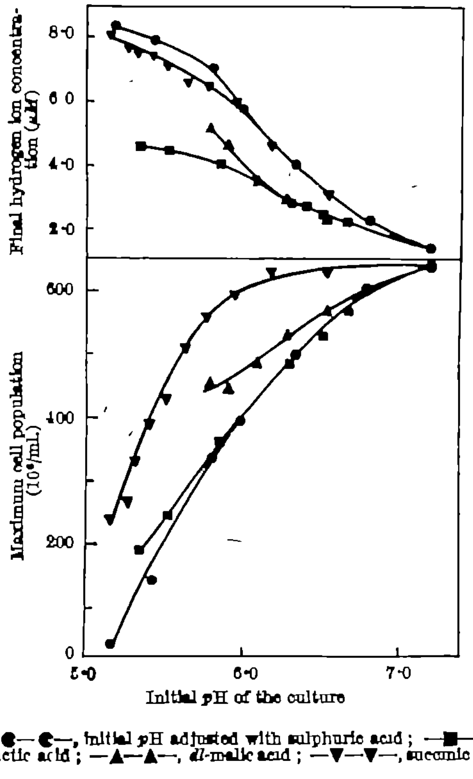
## Anaerobic Growth of *Escherichia coli* in the Presence of Certain Acids

CERTAIN coliform bacteria grow readily under anaerobic conditions in synthetic media containing glucose, ammonium sulphate, phosphate and other necessary inorganic ions. The extent of growth, however, is limited to a definite size of cell population even in the presence of excess concentrations of the substrates, the excess remaining unchanged in the media. This phenomenon has been ascribed to the saturation of the hydrogen acceptor mechanisms, and the evidence supporting this contention is strong[1]. The extent of growth depends also on the initial *p*H and the buffer capacity of the media, being less if the initial *p*H or the buffer capacity is lower. The dependence on buffer capacity has led to criticism of the above suggestion[2]. The growth of such cultures is accompanied by production of acid, but their final *p*H depends on the initial, and growth may stop at a higher *p*H than will permit growth in a fresh medium. Thus, though hydrogen ion concentration is undoubtedly a factor, cessation of growth cannot be due solely to its increase.

Since the production of acid per mole of glucose consumed is considerably greater anaerobically than aerobically[1], it is possible that some of the end-products of the hydrogen acceptor mechanisms are acids and that their production is affected by hydrogen ion concentration. It seemed, therefore, that the effect of adding certain acids to the media would be of interest. The basic medium was buffered with 9·85 gm. per litre potassium dihydrogen citrate adjusted to $p$H 7·2 with sodium hydroxide, and contained sufficient glucose, phosphate and ammonium sulphate to permit the maximum anaerobic growth at this buffer concentration. The organism was *Escherichia coli*, N.C.T.C. 5928, accustomed to the medium and conditions.

In four parallel series of experiments, the effects of additions of lactic, *dl*-malic and succinic acids were compared with those of additions of sulphuric acid. In the diagram, the extents of growth and the hydrogen ion concentrations prevailing as growth ceases are plotted against the initial $p$H. Lactic acid has much the same effect on growth as sulphuric acid, but in all cases the final hydrogen ion concentration is not so great and the difference increases with increase of concentration of lactic acid. At low concentrations the effects of *dl*-malic acid resemble those of lactic acid, but as the concentration increases the results diverge. At concentrations greater than about 6 × $10^{-3}$ *M*, *dl*-malic acid compensates for the decrease in initial $p$H and maintains the extent of growth. Parallel results were obtained with medium at an initial $p$H of 6·2. From 0 to 4 × $10^{-3}$ *M*, succinic acid maintains the extent of growth despite the lower initial $p$H, but does not affect the final hydrogen ion concentration; above this concentration both the extent of growth and the final hydrogen ion concentration are decreased. Above 8 × $10^{-3}$ *M* succinic acid is a more effective inhibitor of growth than sulphuric acid. The three organic acids affect the final hydrogen ion concentration inversely to their own concentration if it lies in a range in which growth is curtailed.



—●—●—, initial $p$H adjusted with sulphuric acid; —■—■—, lactic acid; —▲—▲—, *dl*-malic acid; —▼—▼—, succinic acid

In other experiments with lactic and *dl*-malic acids the initial $p$H was restored to 7·2 by adding appropriate quantities of sodium hydroxide. Up to 9·5 × $10^{-3}$ *M*, either substance decreases the extent of growth down to 500–530 million cells per ml. Thus reduction of the extent of growth can be effected by these acids independently of alterations of the initial $p$H of the medium. Under similar conditions, up to 3·5 × $10^{-3}$ *M* of oxaloacetic acid increases the total growth to 775 million cells per ml. Even without restoration of the initial $p$H, 1·9 × $10^{-3}$ *M* of this acid increases the maximum population to 700 million cells per ml.

The interrelation between inhibition by increase of initial hydrogen ion concentration and by lactic, *dl*-malic and succinic acids would be expected if the undissociated forms of these acids were the inhibitors. The application of this principle could link the capacity of the hydrogen acceptor mechanisms with the buffer capacity of the medium. The three acids studied may be some of the end-products of natural hydrogen acceptor mechanisms; but even if their natural production is not considerable, they would be expected to interfere with a system operating in this manner. It was calculated for experiments in which growth and change of $p$H were small that 1 × $10^{-6}$ *M* of undissociated lactic acid was present. If media containing 6 × $10^{-3}$ *M* of *dl*-malic acid and $10^{-6}$ *M* of undissociated lactic acid at a $p$H of 7·2 are inoculated, growth is restricted to 70 million cells per ml. despite the increase in buffer capacity due to the procedure.

## Chromosome Numbers in *Holcus mollis*

Investigations into the interspecific relations of *Holcus lanatus* and *H. mollis* have shown that their $F_1$ hybrids are male-sterile, having only 1–20 per cent of stainable pollen. Chromosome counts have been made on twenty-three of these hybrids with the results given in Table 1.

Table 1

| Cross | Chromosome number in $F_1$ | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | 21 | 22 | 23 | 24 | 25 | 26 | 35 | 40 | 42 | |
| *H. lanatus* × *H. mollis* | 1 | 2 | 3 | 5 | 2 | 2 | 1 | – | – | Frequency |
| Reciprocal | – | – | 2 | – | 3 | – | – | 1 | 1 | |
| | 1 | 2 | 5 | 5 | 5 | 2 | 1 | 1 | 1 | |

This unexpected range in chromosome number led to a cytological examination of the parent plants. *H. lanatus* was found to have $2n = 14$, a number which confirms the counts of Avdulov[1] and Litardière[2]. *H. mollis*, however, proved to have $2n = 35$, a new number for this species. Earlier investigators have found two numbers, namely, $2n = 14$ (Ståhlin[3]) and $2n = 28$ (Löve and Löve[4] and Litardière[2]).

The discovery of pentaploid *H. mollis* prompted a survey of chromosome numbers in both species

Preliminary results confirm *H. lanatus* as a diploid, while revealing three chromosome numbers in *H. mollis*: tetraploids ($2n = 28$), pentaploids ($2n = 35$) and hexaploids ($2n = 42$) have been found in this species, with frequencies as shown in Table 2.

Table 2

| Species | Area of collection | Chromosome number 28 | 35 | 42 | |
|---|---|---|---|---|---|
| *Holcus mollis* | Aberystwyth | 7 | 30 | 5 | Frequency |
| | Bayfordbury | – | 1 | – | |
| | Durham | 1 | 4 | 1 | |
| | Exmoor | – | 2 | – | |
| | Malvern | – | 6 | – | |
| | Neath | – | 5 | – | |
| | | 8 | 48 | 6 | |

These results show that pentaploid *H. mollis* is the most frequent form of this species, and that in some areas at least it co-exists with the tetraploid and hexaploid forms. More extensive investigations are being made to determine the distribution and relative frequencies of the chromosome types in various areas and their relation to each other.

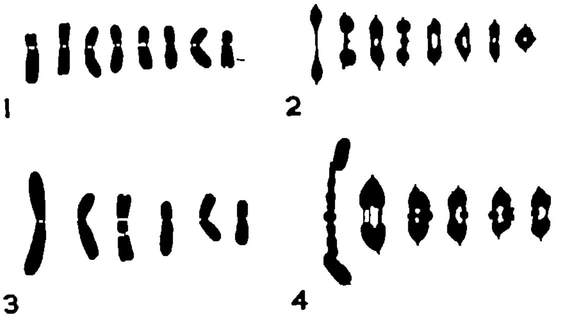
# Species Formation in *Trifolium subterraneum*

Subterranean clover (*Trifolium subterraneum*) is indigenous throughout the Mediterranean region. As an introduced species it is a major component of pastures covering some 10 million acres in Australia, and has contributed largely to the development of the Australian sheep industry during the past thirty years.

A recent paper by Yates and Brittan[1] on *T. subterraneum* reports six varieties, collected in Australia, each with 16 chromosomes ($2n = 16$), whereas two varieties, collected in Israel, had only 12 chromosomes ($2n = 12$). I have examined collections from Australia, England, Israel, Malta, Morocco and Portugal. I found, confirming Yates's and Brittan's report, that the easternmost variety, Israel, had 12, and all the others had 16 chromosomes. I also found that the chromosome complement of the Israel variety, in addition to a general increase in size, includes long chromosomes not present in other varieties (see diagrams).

Thus there are two chromosome races of *T. subterraneum* which are not externally different and one of which has so far been found only in Israel. Further, the Israel race has a new basic number $x = 6$, for the tribe Trifolieæ previously reported[2] only with $x = 7$, 8 and 9. Yates and Brittan compared the size and number of the chromosomes of the Israel variety with those of *Vicia sativa* ($2n = 12$) and suggested parallel evolution from a genus outside the Trifolieæ as a possible mode of origin of the new form.

With regard to size, differences in the size of chromosomes in different plants have been shown to be under genotypic control[3,4] and not necessarily indicative of the origin of the species. Further, Wexelsen[5] has shown differences in chromosome size between different varieties of *Trifolium repens*.



Chromosome idiograms from root-tips: (1) $n = 8$, (3) $n = 6$, and first metaphase configurations: (2) $2n = 16$, (4) $2n = 12$, of *T. subterraneum*. Idiograms drawn from Feulgen squash preparations × 3,000. Meiosis from carmine squash preparations × 1,800

With regard to chromosome number, a more likely suggestion is that the reduction in number is due to rearrangement. If the variety with the reduced chromosome number, $n = 6$, arose in this way from a form with $n = 8$, the changes could have taken place with very little loss of genic material. The greater range in size of the chromosomes of the Israel variety is sufficient to account for the chromosome material from the normal types, even taking into account the general increase in size (see diagram). This rearrangement could result from breakage and reunion of the chromosomes, as suggested by Darlington[4] to account for the different basic numbers in *Fritillaria*. The loss of the centromeres could be explained either by unequal interchanges followed by loss of the very small chromosomes, or by the formation of dicentric chromosomes with extremely short intercentric arms. Such a dicentric would behave as a monocentric chromosome and there would be in effect a fusion of the centromeres.

Such rearrangement has been inferred in *Crepis*[6], where the basic number of the most primitive species, $x = 8$, has been reduced to give species with $x = 7$, 6, 5, 4 and 3. Similarly, in species of *Drosophila* where the primitive species have $n = 6$ and subsequent species $n = 5$, 4 and 3, genetical analysis has confirmed the rearrangement of the chromosomes[7].

The Israel variety of the species has not yet been acclimatized in Australia. Its early-flowering habit would make it of advantage in areas of short seasonal rainfall in Australia. However, its usefulness is limited by its spindly growth habit. All attempts at hybridization with the more leafy types ($2n = 16$) have failed[1]. This inter-sterility and the difference in chromosome number necessitate the recognition of the Israel variety as a cryptic species.

## Fog Fever Syndrome in Parasitic Bronchitis

Two years ago, Hudson, working at this laboratory, described a syndrome that he had observed in adult cattle, of which pulmonary œdema was a feature. He suggested that it might be due to an allergy associated with the small number of lungworms that he noticed were present.

Field studies have shown pulmonary œdema and emphysema to be a common feature of parasitic bronchitis in the adult bovine. The helminthological picture in such cases is very variable. At one extreme there may be large numbers of mature worms present, while at the other only a score or so of microscopic worms may be recovered. Since the development of the worms in the resistant host is often inhibited, their size gives but little indication of the time at which they were picked up.

Clinically, outbreaks of husk in adult cattle make themselves manifest either by a qualitatively uncharacteristic cough, or else, where pulmonary œdema or emphysema or both are present, by a syndrome very closely resembling the condition known as 'fog fever'. This is characterized by dyspnœa and crepitant or squeaking rales. The animal stands with its head stretched out, mouth open and tongue protruded, the ribs are held out and breathing is shallow, rapid and abdominal. The temperature is sometimes high, sometimes normal and may even be subnormal. Generally there is a loud expiratory grunt or groan. Coughing is relatively infrequent.

The occurrence of this syndrome is not confined to adults, and we have observed it in calves after three weeks of exposure to exceptionally heavy natural infection with *Dictyocaulus viviparus*.

We have also been having considerable success in producing the syndrome by the artificial administration of the infective larvæ of *D. viviparus* to young cattle kept under worm-free conditions. We are not able to produce the condition in every animal at will; nor is every case as spectacular as the most acute cases encountered in the field; nor yet is the proportion of deaths any higher than it is in naturally occurring outbreaks. In the twenty-four animals of the present series that have survived the first two months of the initial infection, the syndrome has been observed twelve times. There have been three deaths.

The syndrome, as so far observed, may be recognized as occurring at three stages in our experimental husk infections. Six cases occurred about the time that the initial infection was being spontaneously terminated. Two cases were seen some months after the initial infection had been eliminated, and we believe they may have been associated with the resumption of growth by worms that had been inhibited in their development. Four cases occurred about twelve days after the re-infection of animals that had thrown off the initial infection some time before.

The four circumstances in which the syndrome has been observed, that is, three weeks after first exposure to infection, twelve days after re-infection, about the time the initial infection was being thrown off and when previously inhibited forms may have been resuming their development, are all times at which one might reasonably expect some kind of immune response to be taking place. This would suggest that the condition, the pathology of which resembles that of an allergy, may indeed be related to such a response.

It will be noticed that in the three sets of circumstances in which our artificial fog fevers occur, mature worms will be either few in numbers or absent, while in those cases associated with the spontaneous termination of the infection even immature worms may not be present. This possibility means that the value of post-mortem examination in assessing the cause of naturally occurring cases of fog fever is limited. None the less, the examination of lungs from cases that have been diagnosed as fog fever by clinicians has so far revealed the presence of at least a few lungworms in all six of the lungs that have reached us in good condition.

It would appear from these findings that a proportion of fog fever cases are undoubtedly the consequence of lungworm infestation. The possibility that all fog fevers are associated with this cause cannot be discounted at this stage.

## Transliteration of Cyrillic Script

In *Nature* of March 28, p. 548, the hope is expressed that other countries which use the English alphabet will adopt the Royal Society's scheme for the transliteration of Russian, Bulgarian and Serbian. It is therefore important to point out that the Permanent Committee on Geographical Names for British Official Use (an inter-departmental advisory body) considers the Royal Society's scheme to be unsuited to cartography. Far from letting things take their own course, the Permanent Committee has come to agreement with the United States Board on Geographic Names about the transliteration of Russian and Bulgarian. Serbian is officially written in both the Cyrillic and the Roman alphabets, and to transliterate Serbian geographical names into an English alphabet would produce objectionable variants of their official forms.

In the issue for February 27, 1890 (p. 397), *Nature* offered a system for the transliteration of Russian which was to "be adopted without delay" in the publications of eight leading British learned bodies, including the Royal Society, and which had the support of Russian and American authorities. So far as I am aware, it was not widely put into use, and for a good reason: a system of transliteration, once established in a big library, cannot be changed without great expense, delay and confusion.

The Royal Society has added one more to the dozen or so systems for the transliteration of Slavonic languages already established in British and American use. If agreement in the English-speaking world be possible, it will not be achieved without the co-operation of such bodies as the American Council of Learned Societies; but different English systems for the transliteration of a given foreign alphabet are required for different purposes. A good international system might be better, at least for postal and documentational purposes, than any good national system; but a bad one would be deplorable.

M. Aurousseau

# FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

### Monday, May 25—Friday, May 29

Textile Institute (at Llandudno).—Annual Conference

### Tuesday, May 26

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W 1), at 6 p m —Annual General Meeting, at 7 p.m.—Mr. W. A Goldstein: "The Instrumentation of Pilot and Experimental Scale Plant".

### Wednesday, May 27

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C 1), at 5.15 p m.—Mr. C A Moser and Mr. A. Stuart: "An Experimental Study of Quota Sampling".

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 30 p.m.—Prof. D. Baird and Miss E. M. Scott. "Intelligence and Childbearing".*

Royal Microscopical Society (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p m.—Mr D. Causley. "High Speed Automatic Counting of Microscopic Particles—The Flying Spot Microscope".

### Thursday, May 28

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 4 p.m —Annual General Meeting; at 5.15 p m —Prof. J. A. S. Ritson: Presidential Address.

British Association for the Advancement of Science (at the Royal Institution, 21 Albemarle Street, London, W 1), at 6 p m.—Sir Harold Hartley, F.R.S.: "The Life and Times of Sir Richard Gregory" (Alexander Pedler Lecture). (Admission by ticket obtainable from the Secretary of the British Association.)

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturer or Lecturer in the Department of Pure Mathematics—The Registrar, The University, Liverpool (May 30)

Biologist—The Secretary, King's College Hospital Medical School, Denmark Hill, London, S.E.5 (May 30).

British Coke Research Association Fellowship—The Registrar, King's College, Newcastle-upon-Tyne (June 1).

Research Assistant to work on the fundamental aspects of filariasis—The Secretary, Department of Entomology and Parasitology, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool 3 (June 1)

Senior Lecturer in Mathematics—The Registrar, College of Technology, Birmingham 1 (June 2).

Assistant (with an honours degree in botany) in the Department of Botany—The Secretary, The University, Aberdeen (June 3).

Junior Fellowship in Electrical Engineering—The Registrar, The University, Bristol (June 5).

Assistant Agricultural Economist—The Registrar, Wye College, Ashford, Kent (June 6).

Assistant Lecturer (Grade 3) or a Lecturer (Grade 2) in Inorganic Chemistry—The Registrar, The University, Bristol (June 6).

Esso Studentship in Chemical Engineering—The Secretary, Department of Chemical Engineering, The University, Tennis Court Road, Cambridge (June 6).

Senior Lecturer in Agricultural Economy, a Senior Lecturer in Agricultural Engineering and Farm Mechanization, a Lecturer in Crop Husbandry, a Research Fellow in Soil Science, a Research Fellow in Soil Chemistry, and Soil Analysts (2), at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (June 6).

Lecturer in Agricultural Economics—The Registrar, The University, Leeds 2 (June 8).

Lecturer in Organic Chemistry, a Lecturer in Physical Chemistry, and a Lecturer in Biochemistry (special experience of biochemistry of micro-organisms desirable)—The Secretary, The University, Aberdeen (June 8).

Lecturer and Assistant Lecturers (3) in the Department of Biochemistry (one of the appointments will entail research in certain physical aspects of biochemistry)—The Secretary, University College, Gower Street, London, W C 1 (June 8)

Senior Lecturer in Chemistry at the Fourah Bay College (University of Durham), Sierra Leone—The Secretary, Advisory Committee on Colonial Colleges, 15 Victoria Street, London, S W.1 (June 8).

Assistant Lecturer in Geography—The Secretary, London School of Economics and Political Science, Houghton Street, Aldwych, London, W.C.2 (June 12).

Lecturer (Grade 1) in Geography at the University of Ceylon—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C 1 (June 12).

Research Officer (with Ph D. or equivalent standard with special training in microbiological chemistry) to the Animal Health Research Laboratory, Parkville, Victoria, to carry out investigations in the field of microbiological chemistry—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2, quoting 201/73 (June 13).

Cochrane Entrance Scholarship in Metallurgy—The Registrar, King's College, Newcastle-upon-Tyne (June 15).

Engineering and Physics Graduates (with first- or second-class honours degree in engineering, physics or mathematics) to join a group working on servomechanisms and controls—The Secretary, University Engineering Laboratory, Trumpington Street, Cambridge (June 15).

Lecturer (with a first- or second-class honours degree in mechanical engineering) in the Department of Applied Mechanics, and a Lecturer (with a first- or second-class honours degree in mathematics) in the Department of Mathematics—The Director of Studies, Royal Naval College, Greenwich, London, S E.10 (June 15).

Wood–Watson–Donkin Memorial Scholarships in Metallurgy or Chemistry—The Registrar, King's College, Newcastle-upon-Tyne (June 15).

Lecturer in Anatomy—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (June 18)

Lecturer in Psychology—The Secretary, The University, Aberdeen (June 20).

Plant Physiologist (with good honours degree) at the A.R C Unit of Experimental Agronomy, Oxford, to work on fundamental aspects of phytotoxicity and action of herbicides—The Secretary, Agricultural Research Council, Cunard Building, 15 Regent Street, London, S.W.1 (June 20).

Chief Lecturer in Physiology at the University of Queensland—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C 1 (June 22).

Coal Survey Officer (with good honours degree or equivalent in a science subject, preferably with a sound background in geology and chemistry) in the Central Coalfield of Scotland—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/633 (June 22).

Lecturer in Electrical Engineering (with experience in (*a*) heavy electrical engineering, (*b*) high vacuum engineering, or (*c*) radio-isotope applications and nuclear energy)—The Registrar, Queen Mary College, Mile End Road, London, E.1 (June 22).

Senior Agricultural Economist (to be largely concerned with liaison work between the Provincial Agricultural Economics Service and the National Agricultural Advisory Service)—The Registrar, The University, Leeds 2 (June 22).

Lecturer/Senior Lecturer (preferably with research experience in the fields of plant biochemistry, radio-biology, or bacterial chemistry) in Biochemistry at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (June 27).

Charles Brotherton Scholarship in the Department of Coal Gas and Fuel Industries—The Registrar, The University, Leeds (June 30).

Lecturer in Biophysics (with main research interest in the applications of radioactive tracers in biological and medical investigations)—The Secretary to the University, The University, Edinburgh (June 30).

Research Scholar (with a good honours degree in chemistry)—The Registrar, The University, Reading (June 30).

Foundation Chair of Applied Psychology, the Foundation Chair of Civil Engineering, the Foundation Chair of Mechanical Engineering, and the Chair of Electrical Engineering, in the New South Wales University of Technology, Sydney—The Agent General for New South Wales, 56–57 Strand, London, W.C 2 (July 1).

Chair of Anatomy in the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C 1 (July 10).

Physicist or Engineer (with experience in the field of nuclear accelerators) to take a responsible part in the operation and technical development of the Nuffield cyclotron—The Registrar, The University, Birmingham 15 (July 15)

Assistant Professor in the Department of Civil Engineering—The Registrar, University of British Columbia, Vancouver, B.C, Canada.

Biochemist (non-medical)—Dr. J. M Sherriff, Consultant Pathologist, Hill End Hospital, St. Albans, Herts.

Biochemist (Senior Grade)—The Physician Superintendent, Crichton Royal Mental Hospital, Dumfries.

Head of the Department of Mathematics—The Principal, Borough Polytechnic, Borough Road, London, S E.1.

Lecturer (Grade B) in Physics, and a Lecturer in Physiology—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11.

Mechanical Engineer in the Public Works Department, Sudan Government—The Sudan Agent in London, Sudan House, Cleveland Row, London, S W.1, quoting "M/Engineer 1824"

Meteorological Forecasting Officer (with good forecasting experience) to the Falkland Islands Dependencies Survey, for service at South Georgia in Sub-Antarctic—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M3B/33254/NF.

Physicist for work on (*a*) footwear production and wear problems, (*b*) shoe materials and other products used in the industry—The Director, British Boot, Shoe and Allied Trades Research Association, Satra House, Rockingham Road, Kettering, Northants

Physicist or Electrical Engineer in the Steel Making Division, Sheffield, for research on electric arc furnace problems—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "Arc Furnace".

Research Assistant in Physical or Physical-Organic Chemistry with particular reference to electrochemical or spectroscopic technique—The Principal, Medway Technical College, Gardiner Street, Gillingham.

Senior Research Assistant (with good honours degree in engineering) in the Department of Civil and Mechanical Engineering—The Registrar, The University, Nottingham.

# THE CORONATION

WITH the Coronation the scientist, as such, may appear to have but little concern. Like his fellow citizens, he may be profoundly moved by the pageantry and the tradition to which the Lancaster Herald directed attention in a recent discourse at the Royal Institution, the substance of which is reproduced on p. 948 of this issue. Nor will scientific men be backward in responding to the appeal of the occasion for re-dedication to service to the community in the Commonwealth with which the Queen and her husband have already become so inspiringly associated. Save, however, for those whose interests lead them to probe more closely into the origins of ritual and ceremony and their meaning for the continuity and the structure of society, the interest of men of science in the Coronation is essentially that of citizens rather than of scientists.

Nevertheless, there are reasons why the Coronation and what it represents deserve more than a passing thought from the scientist professionally. It is not simply that the pageantry and solemnity of the proceedings are brought to the ears and before the eyes of many more millions throughout the world than was possible even sixteen years ago, when George VI was crowned. Scientific advance—the astonishing miracle of science—has been the main factor that has made it possible for so many of the Queen's subjects to associate themselves so intimately with her in the very act of consecration and dedication, whereas before they had been limited to the manifestation of loyalty in the thronged processional streets or to viewing later the record of what was already a page of history. In the misgivings with which in some quarters the televising of the ceremony has been regarded, and the anxious debate which preceded that decision, may be sensed an appreciation that the impact of science on society has consequences and implications of which we are as yet only imperfectly aware. The very advances of which science is justly proud have themselves created fresh problems, often of unsuspected significance. The mind and outlook of society as well as its physical environment are being transformed, and the end is not yet apparent.

It would be surprising indeed if in such circumstances the minds of men and women did not turn with fresh and deeper interest to those ceremonies such as the Coronation which, by kindling loyalties and quickening tradition, seem to offer fresh hope of stability and of binding society together in an age when so much tends to erode its fabric. Nor is this all. Men of science are only too well aware of the extent to which, in country after country, the traditional freedom of investigation of the scientist, his right to pursue his investigations and inquiries wherever the disinterested search for truth may take him, has been challenged. The struggle for freedom of investigation and utterance which the nineteenth century deemed to have been won has been re-opened, and in circumstances often far more formidable to freedom than when Milton wrote his noble words in the "Areopagitica".

There are countries where science has at its disposal financial endowments vastly greater than those available in Great Britain, both for fundamental and for applied research. The universal tribute to the pre-eminence of British scientists in fundamental research might well remind us that in no other country does the scientist enjoy greater freedom of investigation and communication, despite all the invasions of that freedom by secrecy requirements arising out of considerations of national security, from which Great Britain, as also other countries, is not immune. So at this time the scientist might well reflect further whether there is not some connexion between that liberty and the nature of our whole system of government of which her gracious Majesty is the titular head.

Between systems of government and the spirit of the communities which they serve there is in fact a close, if intangible, connexion. The scientist never had more reason than to-day for appreciating that, while his professional activities are influencing the community more closely than ever, they are in turn conditioned by the spirit and outlook of the society in which he works and upon whom he depends for support. It is not simply that, to an increasing extent, even fundamental science depends upon public funds for support: the fields in which science can advance, and the rate at which the results of scientific advance are applied, are determined increasingly by public opinion. Indeed, in more countries than one it has become evident that there is real danger that scientific advance may be impeded by mass hysteria and misunderstandings amounting to what has been an antagonism which may constitute a definite anti-scientific trend.

It is in such circumstances that the amateur tradition of science is so important. Scientific advance has always owed much to the work of the amateur. That is still true to-day; and particularly science depends upon the help of the amateur in spreading an understanding and appreciation of what science is doing and the benefits it could bring to mankind. For this reason it is appropriate to recall, as Sir Arthur MacNalty does on p. 951 of this issue, the encouragement which the sovereigns of this realm have given to the pursuit of science and its teaching. The interest and understanding which Queen Elizabeth showed earlier this month at the Royal College of Surgeons was only the latest of a number of occasions on which she and her husband, the Duke of Edinburgh, have given encouragement which scientists, and perhaps especially it should be mentioned, the younger scientists, deeply appreciate and will ever remember.

Lastly, with a Sovereign who has herself shown her interest in science by accepting the fellowship of the Royal Society, the comparisons commonly being made between the present time and the first Elizabethan age cannot but stir the imagination of the historically-minded scientist. When the first Elizabeth ascended the throne, the founding of the Royal Society lay a full century in the future. Already, however, the discovery of America and the circumnavigation of the world had widened men's horizons, and the new learning, notably through the work and teaching of the Oxford 'humanists', More, Grocyn, Colet and Linacre, had started a ferment in men's minds which led in due course to Bacon's "New Atlantis" and to Newton.

No more than the first Elizabethans can we yet discern the new age that is waiting to be born. During the past four centuries, the limits of the physical world have been well-nigh explored. Save for Everest and the increasing mastery of the air, the feats of geographical exploration seem to have been accomplished, and it is with the world of the minute that the future seems likely to be most intimately concerned, whether we think in terms of nuclear research leading to the atom bomb or industrial power, or the way in which the electron microscope and other new tools are laying bare the structure of living tissues. Wherever that may take us, it is increasingly clear that not in the physical world will man find the wisdom and understanding that will enable him to face the future with courage and confidence. The foundation of society in the new Elizabethan age is to be found in the same moral and spiritual values that inspired the greatest of our forbears of that earlier age. The solemnity of the Coronation should take our minds back to that central truth, and as we pledge our loyalty to the Queen who is to be crowned on June 2, we should remember also that in such loyalty and in the respect for and clearer understanding of human values lies the condition both of scientific advance and of social well-being and order.

---

# INTERNATIONAL TABLES FOR X-RAY CRYSTALLOGRAPHY

International Tables for X-Ray Crystallography (Published for the International Union of Crystallography.) Vol. 1: Symmetry Groups. Edited by Norman F. M. Henry and Kathleen Lonsdale. Pp. xi+558. (Birmingham: Kynoch Press, 1952.) 105s.

At a conference in Zurich in 1929 an international group of X-ray crystallographers met to work out the plans for a standard set of tables on space groups and of functions and data needed in practical crystal-structure analysis. The need for such tables arose in the minds of all those who were authors or prospective authors of books on structure analysis. At that time the application of space-group theory had become an accepted practice; furthermore, experimental methods had been standardized and corrections devised for obtaining the most accurate data. In a text-book, therefore, the author had either to include a great volume of already published tables, or to put up with the fact that his book could not be of practical use. Besides, different formalisms and nomenclatures were likely to spread and become firmly established in the schools of the various countries, and this was apt to lead to a great complication of the international literature. The establishing of a single plan for the tables required some sacrifice of pet ideas on the part of each of those who took part in the planning, but the result of the conference and of the subsequent work of the various schools, the "Internationale Tabellen zur Bestimmung von Kristallstrukturen" (Borntraeger, Berlin, 1935; referred to later as "Tab.'35"), have fully justified the advantages of the give-and-take then exercised. Not only have these tables in the original edition and in a war-time photo-offset re-issue done great service in all X-ray analysis laboratories as well as in the teaching of students, but they have also led to a great saving of effort by the acceptance of standard symbolism and methods.

In the twenty years that have passed since the preparation of "Tab.'35" enormous progress has been made in the development and application of new methods of crystal-structure determination, such as the development of new instruments (Buerger precession camera, Geiger counter technique), computing techniques (punched card methods) and theoretical methods (phase inequalities, statistical detection of symmetry elements, Fourier refinement methods). It seems natural that a full re-edition of such tables would be preferable to a minor revision. Besides, the ground had meanwhile been prepared for an easier co-ordination on an international scale than was possible by individual initiative in 1929. The International Union of Crystallography at its very foundation (London 1946, Harvard 1948) set up a committee to prepare a modern set of tables, and, thanks to the untiring activity of its chairman, Prof. Kathleen Lonsdale, the committee has now published the first of the three volumes which will form the complete work.

To start by the 'habit', the volume of five hundred pages is beautifully published for the Union of Crystallography by the Kynoch Press. Paper, binding and print are an impressive sample of craftsmanship, and no misprints have been noticed. The layout, especially for the simpler space groups, is lavish, with an impeccably white lower half of the page inviting one to scribble down notes. The price is kept low by subsidies which the Union received from the United Nations Educational, Scientific and Cultural Organization and from United States sources through the United States National Committee for Crystallography.

Vol. 1 of "Tab.'52" presents the symmetry groups in fundamentally the same way as Vol. 1 of "Tab.'35". The bulk of the volume is formed by the description of each of the 230 space groups. Most of the figures of "Tab.'35" have been taken over; changes had to be made in cases where a more extended description was given, for example, in referring rhombohedral groups to hexagonal axes. The figures for cubic space groups have been omitted. Now it is true that in the cubic system figures are necessarily more schematic than in systems where the presence of at least one singular direction facilitates the orientation; yet I must confess that I feel rather lost without the neat figures of "Tab.'35" by which M. Mauguin found an acceptable solution to an intricate problem of spatial representation. Co-ordinates require careful reading, whereas the diagrams give at a glance a vivid impression not only of the equivalent positions but also of the right- or left-handedness of the surroundings of each equivalent atom.

A major change from "Tab.'35" is the partial separation of the space-group descriptions in physical space from the equivalent in Fourier space: the structure factors are collected for all space groups in Table 4.7 (150 pages), whereas the 270 pages of space-group description, forming Table 4.3, after listing the co-ordinates of equivalent points, do not go beyond a listing of the absent reflexions, omitting previously listed information (for example, subgroups) which was considered of minor practical value. While the present separation and curtailment may not inconvenience the practical worker, yet the old arrangement had the unquestionable advantage of offering at one place a complete dual description of each space group in crystal and in Fourier space.

In the monoclinic system the twofold symmetry axis is traditionally taken as the *b*-axis; this orientation is generally accepted throughout the older crystallographic and mineralogical literature. On the other hand, a unique axis is taken as the *c*-direction in all other crystal systems, and the derivation and handling of space groups is slightly more unified if this convention is also adopted in the monoclinic system. The authors of "Tab.'52" have tabulated monoclinic groups in both settings. It is to be hoped that the users of "Tab.'52" will be aware of the recommendation of the Stockholm Assembly (see *Acta Cryst.*, **4**, 569; 1951) that "the use of the *c*-axis as the unique axis is acceptable where there is a special reason for this setting, in which case the reason should be stated". Normally, therefore, the second setting should be used in "Tab.'52" so as to avoid a clash with the very extensive existing literature.

Among the novel material of the space-group tables a list of the symmetry properties of $|F|$ must be mentioned. For $P4_1$, for example, this takes the form:

$$|F(hkl)| = |F(\overline{hkl})| = |F(h\overline{kl})| \neq (F(\bar{h}kl)|\,;$$
$$|F(\bar{h}kl)| = |F(h\overline{kl})|.$$

This statement is far from expressing completely the symmetry properties of $|F|$. What about $|F(hkl)| = |F(\bar{k}hl)|$, the result of the fourfold axis? Throughout the reported symmetry relations, the order of the indices $(hkl)$ in the argument of $F$ is preserved; in other words, only the symmetry of $|F|$ which is caused by twofold axes or $x$, $y$, or $z$ reflexion planes is listed. On the other hand, the obvious centrosymmetry of $|F|$ is repeated for every single space group. The extensive introductory note of the structure-factor tables offers no help in understanding the principle of this selective listing of the symmetry of $|F|$.

Some tables of "Tab.'35" have been omitted as being of minor practical value: these are mainly the collective tables on lattice complexes, which formerly occupied twenty-six pages, and the list of lattice complexes, non-generating symmetry elements and sub-groups which were provided under the heading of each space group. Part of this material is offered in a condensed form in Table 5.2 (three pages) on sub- and super-groups of the space groups. References in the explanation of this table might well have included "Tab.'35", where a full list is to be found.

The progress in methods of using experimental data is reflected in the inclusion of the expressions for Fourier synthesis, that is, the explicit form of the Fourier series for $\rho(x, y, z)$ in each space group. This important information was not contained in "Tab.'35" and was first published in Prof. Lonsdale's "Structure Factor Tables" (George Bell and Sons, Ltd., 1936). Also new are Tables 5.3 (space-group determination by methods outside the Friedel law) and 5.4 (inequalities arising from symmetry elements), both occupying about one and a half pages. The latter lists the special forms of Harker–Kasper inequalities in the presence of symmetry elements; the former section is mainly a description of the statistical treatment of intensities along the lines inaugurated by Dr. A. J. C. Wilson.

Further welcome additions are tables on the space groups of lower dimensionality, namely, the two linear and the seventeen planar groups (that is, the two groups on a line and the seventeen groups in a plane). These are important for the classification of the symmetry of projections of space groups or of sections through space groups, and have been fully tabulated. Of perhaps greater physical importance are the groups with one translation (seven in the plane (borders), thirty-one in space) and the eighty groups (nets) with two translations in which the particles are allowed to lie in three-dimensional space (for example, a woven tissue). These have been mentioned but not tabulated in the note on p. 56; more general knowledge of these groups seems desirable, and inclusion in the present volume would have greatly improved their accessibility.

The text explaining the tables and their use is clearly and carefully written; it offers more explanation than that of "Tab.'35". Altogether, one notes the tendency to facilitate the use of the tables by workers who have little more than a general idea of space groups. This is an acknowledgment of the fact that this rather mathematical tool is being used to an ever-increasing extent by chemists and biologists whose main training cannot include the details of an intricate mathematical theory. Examples of the use of the tables are often given, and I agree wholeheartedly with this; on the other hand, I feel strongly that a volume of tables should not attempt to teach methods, like a text-book. Neither is it the place for a historical article surveying the development of space-group theory and crystal-structure analysis (pp. 1–5). A very welcome innovation, however, is the last table, Table 7 (five pages), which is a dictionary of crystallographic terms in English, French, German, Russian and Spanish; this in a way replaces the trilingual text of "Tab.'35". The rather embryonic dictionary seems to be limited to terms occurring in the text of Vol. 1, but it is a good start for a more general dictionary of terms likely to be encountered in papers on structure analysis. Some rather unusual German terms and others which have been omitted have been noted: for 'Habit' *Tracht* should have been given, since *Habitus* is easily recognizable. The expression *Hydrostatischesmodul* (*sic*) for *Kompressionsmodul* is unlikely to be encountered. The use of *Stab* for line in *Reflexionsstab* and in *Symmetriestab* is new to me, but may be a modern development. Thermal vibration is usually *Wärmeschwingung*, and the correct rendering of 'moving-film method' would be *Goniometermethode* and not the impossible *bewegend-Film-Methode*.

The foregoing criticism of detail should not detract from the fact that the authors and in particular the editors, Dr. N. F. M. Henry and Prof. K. Lonsdale, have performed a splendid and most unselfish service to the large group of crystallographers who benefit by the use of such tables. The new work is an adaptation of the results of theory by experimentalists of long standing for the benefit of experimentalists, and is based on the experience obtained with the older set of tables. Some innovations are obvious improvements, others appear questionable, but only the prolonged use of the tables will bring out fully their virtues and their foibles. P. P. EWALD

## ADVANCES IN AGRONOMY

Advances in Agronomy

Prepared under the auspices of the American Society of Agronomy. Vol. 3. Edited by A. G. Norman. Pp. x+361. (New York: Academic Press, Inc., 1951.) 7.80 dollars.

MANY sciences now have their annual volumes of "Advances", consisting of summaries of particular sections of the subject written by specialists. Agronomy, the study of crop production and soil management, began to be so surveyed in 1949 by the American Society of Agronomy with authors working under Dr. A. G. Norman as editor. The third volume has now appeared. In so wide a field there is abundant choice of material, and almost any subject considered over an area as varied in its conditions as the United States presents a formidable array of data, with the result that most of the contributions are necessarily lengthy and carry numerous references to the literature. Papers such as that on the subsoil, and one dealing with the chemistry of soil potassium, are not, nor are they intended to be, easy reading. The student has to work for his information, but the material is clearly set out to enable him to do so.

In addition to the two papers mentioned above dealing with various aspects of the soil, two deal with legume and herbage plants, two with systems of management of soil conservation and irrigation, and one with a disease problem—the control of soil nematodes. Vol. 3 also contains an excellent survey of recent changes in British agriculture by J. A. McMillan, of the National Agricultural Advisory Service.

In evaluating soil the surface soil commonly receives more attention than the subsoil. It is true that as a seat of soil nutrients the subsoil is generally, though not always, much inferior to the surface, but its properties in respect of root penetration and drainage are of great importance. In the article on this the author deals with the physical properties, clay minerals and fertility-levels of subsoils in the broad soil classes of the United States and discusses at length the characteristics of the various subsoil pans that occur. Interesting sections deal with the difficult and sometimes unsolved problems of the management of subsoils exposed by soil erosion, and the bad effects of subsoil compaction caused by the use of heavy tractors, especially in wet conditions.

A comprehensive paper on soil conservation summarizes the position reached and scientific problems raised by work carried out under the large government schemes that have operated since 1933. The problems are not entirely technical; in fact the most obstinate ones arise from the fact that no farmer takes kindly to alterations in his system which cost money, involve learning fresh skills and may, at the outset at any rate, result in lower returns.

Rather similar treatment is accorded to the subject of irrigation and soil research. The emphasis here is on the need for complete and reliable scientific information derived from both laboratory and pilot farms before a big scheme is launched. This applies to surface irrigation in the arid areas and also to overhead supplemental irrigation in wetter districts. The modern factorial field experiment is essential in studying the inter-relation of fertilizers, water supply and cultivations. The effect of big schemes on the water economy of whole districts needs to be looked into.

A very readable article on chemical treatment of the soil for nematode control shows that soil fumigation has got past the purely experimental stage; the author estimates that fumigants sufficient for a hundred thousand acres were produced in 1950, the chief being ethylene dibromide. As yet, the process is only warranted for high-value crops, and the eelworm population is checked rather than wiped out.

# THE BIRTH OF NEO-POSITIVISM

## The Vienna Circle

The Origin of Neo-Positivism; a Chapter in the History of Recent Philosophy. By Prof. Victor Kraft. Translated from the German 'Der Wiener Kreis' by Arthur Pap. Pp. xii+209. (New York: Philosophical Library, Inc., 1953.) 3.75 dollars.

HOWEVER rapidly philosophical climates may change, and whatever may prove to be the capricious nature of their characteristic cycles, there are certain epochs which will always stand out. One of them is assuredly that of the Vienna Circle. Postponing for the moment a more detailed consideration of its *Lebenslauf*, it is meanwhile worth recollecting that to many scholars in Great Britain it was always 'Der Wiener Kreis", a sure token of affectionate regard; and this in spite of a healthy determination to be the candid friend, avoiding like the plague all semblance of merely polite approval. Thus, as the author says, in Britain and in the United States its purpose found understanding and its tenets secured respect. Not so, however, in contemporary Germany, wherein many cross-currents (not all of them wholly fortuitous) combined to make very heavy weather for the evangelists of neo-positivism.

It is essential to see Prof. V. Kraft's book against such a background. Further, one may dislike the Circle's particular criterion of verifiability and its rather facile (and over-frequent) use of the adjective 'meaningless'—in fact, much of the stock-in-trade—and yet agree what great things it has accomplished. For this is a close-up view, not so much of the creed as of the people who fashioned it, and who passionately believed in it. For those reasons alone, a version in the English language is welcome. Would that—even allowing for its production on the western side of the Atlantic—it was a better version. Epistemological German is notoriously hard to translate, and even harder to make live; but *ebenso*, some of the text as it now appears is far from lovely, and moreover, many of the blemishes upon it are utterly needless.

The core of the volume consists of two long sections: logic and language, and empiricism. As might be expected, these form a commentary—and a very just one—upon the work of Carnap, Wittgenstein and their colleagues, on one hand, and of the critics on the other. The basic division is between the 'logic of science' and the special sciences. The latter are held to be concerned solely with questions of fact, to be validated by experience. Epistemology must have nothing to do with such things; its task is to deal with the logical structure of scientific knowledge. At the same time, philosophical method itself is required to conform to scientific principles.

Towards the end, we find a noble attempt to face up to the axiological import of the Vienna Circle's outlook. Obviously, it was heavily conditioned by a reaction against German metaphysics. Yet, conceptual poetry and even personal wisdom are not denied: upraised on their own pedestal they stand, but qualified as subjective and unverifiable in that they lack universal validity, and therefore the title, to represent knowledge.

Nobody can rightly quarrel with such a statement, the result of years of labour, thrust and counter-thrust by honest men engaged in the quest for truth. But they themselves would be reluctant to claim that the last word had been spoken: the Circle has been disrupted and its members scattered, some luckily to find shelter in calmer waters. Down the years, too, death has taken a heavy toll, but the search goes on, at once courageous (sometimes perhaps almost foolhardy) and relentless. F. I. G. RAWLINS

# BENJAMIN THOMPSON, COUNT RUMFORD

## An American in Europe

The Life of Benjamin Thompson, Count Rumford. By Egon Larsen. Pp. 224+28 plates. (London: Rider and Co., Ltd., 1953.) 15s. net.

THIS book is described by the publishers as "the first popular yet authoritative biography" of Benjamin Thompson, Count Rumford, and its publication was timed to coincide with the bicentenary in March 1953 of his birth. It is a very readable short account of his life and activities, or certain aspects of them. Mr. E. Larsen has been at great pains to collect information in the various places where Rumford lived and worked, and we are indebted to him for some new and interesting particulars—for example, the information on the laying out and subsequent history of the English garden in Munich and that on the house at Auteuil which was Rumford's last home. Some of the illustrations, which are good, are from photographs by the author.

It is not a book to go to for an estimate of Rumford's achievements as a man of science. The references to his fundamental researches on heat are scanty, and the author has not attempted anything in the nature of a connected account of his scientific work. There is a fuller and more satisfactory treatment of his measures of reform in Bavaria, his work for the poor in Munich, and the methods of fuel economy and designs of stoves and fireplaces which he introduced in his workhouses and military establishments. Emphasis is rightly given to his pioneering efforts in the application of scientific principles to purposes of this kind.

A chapter is devoted to his later period in England and his activities in connexion with the founding of the Royal Institution. At the end of the book a well-chosen series of extracts from Rumford's essays, indicating the varied nature of his interests, extends to some forty pages.

It is, however, on a personal and biographical thread that this book hangs, and if the treatment of such matters as Rumford's relations with his daughter and with his second wife, the widow of Lavoisier, is somewhat journalistic, it is none the less interesting. Biographical writing on Rumford begins with Ellis's invaluable "Memoir", published in 1876, and, although much has been written since, the character of the man remains in certain respects somewhat shadowy. In his more personal affairs he covered up his tracks, and the impression persists that the full story of his life has yet to be written.

T. MARTIN

# TRADITION AND THE CORONATION*

## By ARCHIBALD G. B. RUSSELL, C.V.O.

Lancaster Herald,
College of Arms, Queen Victoria Street, London, E.C.4

THE solemnity of the coronation of kings and queens has from the earliest days taken a supreme place in the imagination of the people. How much more so is it the case to-day, since it has come to typify in a very real sense the unity of the British Commonwealth of Nations under the Crown.

Westminster has been the scene of the coronation since it was chosen by William the Conqueror as the place for his own coronation. The earliest Christian coronation of an Anglo-Saxon king of which record remains is that of Egfrith, whom his father, Offa, King of Mercia, had crowned as his successor in 785†.

In the tenth century it was usual for coronations to take place at Kingston-on-Thames. It was on the 'King's Stone', which is still treasured there, that kings were crowned. The use of a sacred stone for this purpose follows a very ancient tradition which was later carried on with the Stone of Scone down to the present day.

Westminster Abbey as it now stands was in greater part built under the direction of King Henry III in the middle of the thirteenth century. It replaced two previous churches on the same site. Its immediate predecessor was the church built by Edward the Confessor and consecrated in 1065, which replaced the original Saxon church and in which the Confessor himself was buried. It was in this church that William the Conqueror and his successors were crowned. It was part of the original plan that the church built by Henry III should be used for coronations, as is evidenced by the unusual feature of the space left between the Choir and the High Altar. It is upon a raised platform erected upon this space, known as the Theatre, that the greater part of the coronation ceremony takes place.

A manuscript of the life of King Edward the Confessor in the Cambridge University Library contains two beautiful drawings, in each of which the artist seeks to convey the impression of religious exaltation. In one of them the King is being anointed with the holy oil. It is this King who is venerated as a national saint, and to whose kingly virtues we owe the greatness of the Palace and Abbey of Westminster. The other drawing depicts the coronation of Queen Edith, his consort.

In the coronation scenes which decorate the exterior walls of the King's Chantry Chapel in Westminster Abbey there is a carved group representing the coronation of King Henry V. It is at once a historical document and a valuable work of art. The crown is being set upon the King's head by the Archbishop of Canterbury and the Abbot of Westminster. The then Abbot was the famous William of Colchester, the 'grand conspirator' of Shakespeare's play. The monumental grandeur of the presentation and the noble pattern of the Royal Arms which accompanies it give it a place as a work of sculpture among the most moving of any produced in Britain. The majestic stillness of the central figure of the King is superbly enhanced by the upward movement of the flanking figures.

### The Banquet

Of the services referable to the banquet which formerly succeeded the coronation, in the Great Hall at Westminster, that done by the King's Champion surpasses all others in its romantic appeal.

This privilege has been in abeyance since the discontinuation of the banquet, which was last held on the occasion of the coronation of King George IV. The service is associated with the ownership of the Manor of Scrivelsby in Lincolnshire, which was held from very early times by the family of Dymoke. In lieu of this service, the Union Standard will be carried by Captain J. L. M. Dymoke at the forthcoming coronation.

A lively study of the Champion appears in a tinted drawing accompanying the pedigree of Dymoke in the original Visitation of Lincolnshire of 1564 at the College of Arms. It is the likeness of Sir Edward Dymoke of Scrivelsby, who was Champion at the coronations of King Edward VI, Queen Mary I and Queen Elizabeth I. His fancifully decorated armour of astonishing richness and the superb trappings of the horse are characteristic of the first Elizabethan Age. He is depicted at the dramatic moment when, after issuing his challenge and offering to combat with the "false traitor . . . who shall deny or gainsay our sovereign lord the King", he is about to fling down his gauntlet.

### The Earl Marshal

The Duke of Norfolk, who holds the hereditary office of Earl Marshal of England, is responsible for the whole of the arrangements for the coronation, with the exception of the church liturgy, which is ordered by the Archbishop of Canterbury. The Duke holds hereditary office, granted to his family by King Charles II in 1674, who conferred it on Henry Howard, Earl of Norwich, afterwards Duke of Norfolk, and his heirs.

The office derives from that of Marshal of England, which was one of the five great offices of state. The earliest holder of the office of whom we have record was one, Gilbert, whose descendants adopted the surname Marshal in virtue of their office. Later it passed to the Bigods and to the Mowbrays and afterwards to the Howards, though it did not actually become hereditary in their family until 1674.

Charles II, in his declaration of the authority of the Earl Marshal, described him as "the next and immediate Officer under Us for determining and ordering all matters touching Arms, Ensigns of Nobility and chivalry", and the officers of arms as "Ministers subordinate to our said Earl Marshal".

### The Officers of Arms

The Kings, Heralds and Pursuivants of Arms who assist the Earl Marshal in the coronation preparations and who take part in the Abbey processions have also certain other duties to perform on the occasion. Among these are the handing over of the canopy to the Knights of the Garter who hold it over the Queen for the anointing, and the leading up of the senior peer of each degree to pay homage to Her Majesty. Scottish Heralds are also present, headed by Lyon King of Arms, and Ulster is now represented by Norroy and Ulster King of Arms.

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on April 24.

† For certain of the historical data I am indebted to the several publications of Mr. Lawrence E. Tanner, keeper of the Muniments and Library, Westminster Abbey.

Officers of Arms are known to have been in attendance at coronations from the time of that of King Henry IV, and it may, I think, be assumed that they did so at an earlier date.

The tabard which they wear on all state occasions is probably the most ancient ceremonial garment still in use, dating back to the second half of the fifteenth century and deriving from the court dress of that period. The tabards of the Kings of Arms are of velvet, those of Heralds satin, and those of Pursuivants damask silk.

On the death of the Sovereign the accession of the new Monarch is proclaimed by one of the Officers of Arms at four different centres in London. At a later date the coronation is proclaimed by the same four Officers at the same places.

The Officers of Arms are appointed by letters patent under the Great Seal of England. They are, under the Earl Marshal, responsible for the granting of arms, the marshalling of state ceremonies and other duties. The coronation is, of course, by far the most important of the state ceremonies with which they are concerned.

## Sir Robert Vyner

Sir Robert Vyner, who was responsible for making nearly all the items of the present Regalia to replace those destroyed at the Commonwealth, began his career as a goldsmith as the apprentice of his uncle, Sir Thomas Vyner, who served the office of Prime-Warden of the Goldsmiths' Company. Sir Robert was born in Warwick in 1631, and in 1661 he received a grant of the office of 'King's Goldsmith'. Like his uncle, he served as Prime Warden of the Goldsmiths' Company. He was on intimate terms with Charles II, and made the Regalia for Charles's coronation at a cost of more than £30,000. He died at Windsor Castle in 1668 and was buried at St. Mary's Woolnoth, Lombard Street, London.

## St. Edward's Staff

St. Edward's Staff was in early times delivered into the Sovereign's hands on entering the Abbey. It is now borne in the procession and this time will be carried by the Earl of Ancaster. The present Staff is part of the 1661 Regalia. The original, which was one of the relics of St. Edward, was a long iron-shod sceptre, and was reputed to contain a piece of the True Cross. The present Staff is surmounted by a golden orb, and the foot is tipped with steel.

## The Maces

The two Maces were made by Sir Robert Vyner for the coronation of King Charles II. The heads are divided into four panels, each containing an emblem surmounted by a crown, and representing the constituent elements of the United Kingdom. Above is an arched crown, on the rim of which are alternate crosses and fleurs-de-lis. The crown is surmounted by an orb and cross. The Maces are carried by the Serjeants-at-Arms.

## The Coronation Chair

The Coronation Chair was made for King Edward I, and was designed to hold the Stone of Scone which he removed from Scotland in 1296. The chair is of oak and was completed in 1300–1. It has been used for all coronations since that of King Edward II.

The back of the chair was originally painted with a seated king. Few traces of this now remain, and much of the original enrichment of gold and colours has perished. A superb early fourteenth century illuminated manuscript in the library of Corpus Christi College, Cambridge, portrays the Chair as it appeared not long after it was made. In this the four lions now supporting the Chair are absent, so presumably these were a later addition. The Chair, which has suffered much in the passage of time, is a rare example of the cabinet work of its day, and is probably to be regarded as the most venerable object associated with the coronation.

The Stone of Scone is first heard of in the thirteenth century, when it was preserved in the Abbey of Scone and was used in the consecration of Scottish kings. It is of reddish-grey sandstone, and was probably quarried in the neighbourhood of Scone. It has been identified in legend with the stone upon which Jacob rested at the time of his vision of the Ladder.

## The Recognition

The coronation ceremony is initiated by the act of Recognition. This is a survival from the remote past when the choice of a sovereign rested upon an electoral basis.

## The Oath

The Recognition is followed by the Oath. The form of the Oath has from time to time undergone revision from the fourteenth century onwards. The latest substantial alteration followed the reign of James II, who was a Roman Catholic, and at the coronation of King William and Queen Mary it was drastically changed with the view of ensuring the maintenance of the Protestant faith. A further innovation introduced at that time was the presentation to the Sovereign of the Bible as "the most valuable thing that this world affords".

## The Anointing

In accordance with ancient tradition, it is with the anointing of a Sovereign with oil, rather than the actual crowning and the investiture with the Regalia, that the climax of the coronation ceremony is reached. The Monarch has been held in the past to assume a mixed personality of a semi-sacerdotal character. For Melchizedek, the priest-king, has remained through all time the type of kingly perfection; in fact, the name may mean 'kingly righteousness'. The antiquity of the rite of the anointing of kings is recalled in the anthem which is sung beginning "Zadok the Priest and Nathan the Prophet anointed Solomon the King".

During the Anointing a canopy is held over the Queen by four Knights of the Garter. She is thus nearly concealed from view during the rite in view of its secret and mystic character.

The Ampulla is an eagle of gold containing the holy oil with which the Sovereign is anointed, the oil being poured out through its beak. It has been suggested that the Ampulla may be in essentials an original work of the time of Henry IV, the engraved decoration and the pedestal upon which the eagle is mounted being the work of Sir Robert Vyner. Against this view is the fact that descriptions of the medieval Ampulla speak of it as a "dove of gold set with pearls and stones", while the existing Ampulla is stated to show no signs of ever having been set with precious stones.

The anointing Spoon escaped destruction in 1649, and is the oldest piece of plate used at the coronation. The bowl may have been re-worked by Vyner; but the stem, which is of exquisite workmanship, dates from the twelfth or early part of the thirteenth century. The Spoon is of silver heavily gilt, and ornamented with elaborate gold chasing, enamels and pearls. The bowl is engraved and is divided with a central ridge.

### The Spurs

The ceremony of the Spurs follows the Anointing. They are brought from the Altar, and the Queen touches them with her hand, for they are emblems of knightly chivalry. They are of gold, with straps of crimson velvet, and were made for the coronation of Charles II.

### Swords

Five ceremonial swords are borne at the coronation. The two-handed Sword of State is the most imposing. It is also carried at state openings of Parliament. Two other swords are known as the Pointed Sword of Spiritual Justice, or Second Sword, and the Pointed Sword of Temporal Justice, or Third Sword. The Queen's personal sword is known as the Jewelled Sword.

But historically the most interesting sword is Curtana. This is the Pointless Sword of Mercy. It was first mentioned by name at the coronation in 1236 of Queen Eleanor, wife of Henry II. The earliest representation of this Sword that I know of occurs in the portrait belonging to the Society of Antiquaries. This portrait has long been regarded as the likeness of Richard III; but I find it difficult to endorse this identity. I suggest that the sitter may in fact have been Henry Percy, fourth Earl of Northumberland, who, at Richard's coronation in 1483, is recorded as carrying "the pointless Sword, naked in hand, which signified Mercy".

The word 'Curtana' is doubtless derived from the Latin *curtus*, meaning shortened or curtailed.

### Armillæ*

The coronation Stole, formerly known as the Armil, or Armilla, is not, strictly speaking, a stole. In religious ceremonies the Stole succeeds the Alb immediately; but in the coronation service it succeeds the Dalmatic, as it did in the eleventh and twelfth centuries, and it is still worn by deacons of the Orthodox Church. Its assumption at the coronation accordingly preserves the medieval custom which the Western Church has lost. It is a strip of material worn about the neck, having depending ribbons at its extremities which were there for a very particular purpose. In length, this strip should be an ell, that is, forty-five inches. Now, such a strip cannot be a stole, which is a vestment as long again. (The stole is intended to remind its wearer of the halter put about Christ's neck when on His way to be crucified.)

The appellation 'Armil' may be explained in the following way. At former coronations extending to that of Queen Elizabeth I, the Sovereigns were invested with wristlets (or bracelets) or armlets. Queen Elizabeth I is said to have worn 'garters' on the upper part of her arms. It is probable that this short strip of material placed about the neck of the Sovereign was not intended to be a stole but merely a means of preventing the slipping-down of the Armils which were attached to it by means of double ribbons at each extremity. Hence the name given to it, which either became confused in the course of time with the Stole or, after the Tudor period, made to serve both to restrain the armlets or bracelets or as a stole proper.

When the Regalia were made for Charles II in 1661 wristlets or bracelets were provided; but they have never been used. They may still be seen in the Jewel House in the Tower of London. It may be remarked that no words accompany the putting on of the Stole, which might support the view that it was only a means of restraining the armlets formerly worn. The last recorded occasion of the use of the Armillæ was at the coronation of Edward VI. It is not known whether they were used at that of Queen Mary I. They are not mentioned in the ceremonials of Kings James I and Charles I, and the pair that were in the Regalia were, in all probability, destroyed when the rest of the royal ornaments were broken up during the interregnum. Another pair was produced in 1661 for the coronation of Charles II, though they were not used, and they have not been brought forward at any succeeding coronation.

Armillæ were well known in the histories of ancient nations, and are mentioned in the Old Testament as having been worn by King Saul. They were the distinguishing marks of the king and warrior. At the forthcoming coronation, the Archbishop of Canterbury when investing the Queen with the Armillæ will say the prayer beginning: "Receive the Bracelets of sincerity and wisdom". These words appear in the order of the service recorded in the *Liber Regalis* of the fourteenth century.

The Armillæ, which were made in 1661, bear enamelled representations of roses, thistles, shamrocks and fleurs-de-lis. The pair that have just been made are of plain gold unadorned, except for a spiral floral design near the edges, and the snap, which is formed of a Tudor rose. They are the combined gift to the Queen of the Governments of Australia and of Southern Rhodesia.

### The Orb

The Orb is a sphere of gold surmounted by a jewelled cross set upon an amethyst. It dates from King Charles II's coronation, and is a symbol of the sovereignty of Christ. A representation of the Orb appears upon a number of early Great Seals of British kings; but it is not mentioned in connexion with any medieval coronation.

### The Ring

The Ring is put by the Archbishop on the fourth finger of the Queen's right hand. It is described as "the ensign of kingly dignity, and a defence of the Catholic Faith". It is set with a sapphire, with a cross in rubies on it. The ceremony of the investiture with the Ring goes back at least as early as the tenth century.

### The Sceptre with the Cross

The Sceptre with the Cross, or Royal Sceptre, symbolizing power and justice, was made for the coronation of King Charles II. It is of gold, and is three feet long. The largest portion of the Star of Africa, cut from the Cullinan diamond, was inset in the head in 1911. Above is an orb of amethyst surmounted by a diamond and enamelled cross. Sceptres as emblems of kingly power are, of course, of great antiquity.

---

* For the data relating to the Armillæ I am indebted to Mr. Gerald Henderson.

### Rod with the Dove

The Rod with the Dove is the symbol of equity and mercy, the Dove being the emblem of the Holy Ghost. It is part of the 1661 Regalia. The gold staff is decorated with jewelled bands. The Dove, which in medieval times was of gold, is now of white enamel.

### St. Edward's Crown

St. Edward's Crown in its original form was his own Crown taken from his grave in 1269. This was ordered by Cromwell to be destroyed with the other Regalia in 1649. The new Crown, much in its present form, was made by Sir Robert Vyner for King Charles II. It has been suggested, however, by Mr. Martin Holmes, that the original crown of St. Edward's was not in fact destroyed, and that it formed the basis of that made by Vyner.

The circlet, or rim, of the Crown, which is of gold, bears alternate crosses and fleurs-de-lis, and from the crosses rise the intersecting arches with, at the top, a globe surmounted by another cross, the whole being richly encrusted with precious stones.

The Crown, after the anointing, and the successive stages of the Investiture, is set upon the Queen's head by the Archbishop of Canterbury.

### The Imperial State Crown

The Imperial State Crown was made for Queen Victoria, and has been slightly altered for subsequent coronations. In the front is the famous gem known as the Black Prince's Ruby. On the rim beneath it is another portion of the Cullinan Diamond. The sapphire in the cross surmounting the Orb at the top is traditionally believed to have come from the Confessor's ring; but it has been recut in modern times.

The Imperial State Crown replaces that of St. Edward shortly after the crowning has taken place.

---

## SCIENCE AND THE SOVEREIGN

By Sir ARTHUR MacNALTY, K.C.B.

At this time of Her Majesty's Coronation, it is appropriate to remember the encouragement which the sovereigns of this realm have given to the progress of science and its teaching.

The Middle Ages were intolerant to science. Roger Bacon, who made discoveries in optics and chemistry, had his books banned and was imprisoned for "suspected novelties"; Bolingbroke, mathematician and astronomer, "the greatest clerk of his age", was hanged and quartered as a wizard.

Then came the great invention of printing which gave to letters and to science the precision and durability of the printed page. Edward IV bestowed his patronage on Caxton, and Richard III during his brief reign encouraged the new invention.

In the reign of Henry VII the light and wisdom of the Italian Renaissance was brought to England by the Oxford "Humanists", Grocyn, Colet and Linacre. Henry VIII, whom Erasmus termed the "scholar king", was a highly accomplished monarch. He wrote excellent Latin, spoke French, Italian and Spanish, was musician, poet, naval architect, a master of ordnance, an amateur of medicine and a good mathematician. He delighted to converse with his learned subjects, appointed astronomers royal, and elevated medicine and surgery in status by founding the College of Physicians on Linacre's advice in 1518, and uniting the barbers and the surgeons as the Barber-Surgeons' Company in 1540, probably at the request of his serjeant-surgeon, Thomas Vicary. He also founded regius professorships of physic at Oxford and Cambridge. He first bestowed the honour of knighthood on two physicians, Sir Thomas Elyot and Sir William Butts. Edward VI knighted his surgeon, Sir John Ayleff. With royal approbation, Edward Wotton (1492–1555), of Padua and Oxford, and physician to Henry VIII, published the first systematic treatise on natural history, and William Turner, Dean of Wells, was the first Englishman to study plants scientifically. His "Herbal" of 1548 marks him as the father of English botany.

Queen Elizabeth I encouraged science. William Gilbert, president of the Royal College of Physicians, who founded the sciences of magnetism and electricity, was her physician and was awarded a pension by the Queen to enable him to conduct his researches, which Francis Bacon quoted in the "Novum Organum" as examples of the method of experiment. John Caius (1510–73), also a president of the Royal College of Physicians, the friend and pupil of Vesalius, was physician successively to Edward VI, Mary and Elizabeth. He wrote a treatise on the sweating sickness, and was a good classical scholar, anatomist and zoologist. Gesner, in a letter to Queen Elizabeth, termed him "the most learned physician of the age". She was a judge of scientific merit, and on her visits to Oxford and Cambridge was accustomed to preside over the disputes in the Physic Act for medical degrees. To James I, Francis Bacon dedicated his philosophy of inductive science which improved instructed thought and commended to the King the regeneration and restoration of the sciences.

The ill-fated Charles I was an enlightened patron of science as well as art and letters. William Harvey was his physician and the King showed the liveliest interest in his researches, being personally present, as Harvey records with pride, at a demonstration of the circulation of the blood and giving him facilities to use the deer in the royal parks for his pioneer work in embryology. King Charles also nominated Harvey as warden of Merton College, Oxford.

One of the greatest royal patrons of science was King Charles II. He founded the Royal Society in 1662, presented it with a silver-gilt mace, and presided at its inaugural banquet and at several meetings of the Society. He studied anatomy and chemistry, and his cousin, Prince Rupert, made several discoveries in chemistry. The King was always interested in new discoveries in the realm of science, as Pepys and John Evelyn tell us. King Charles "had yet skill to discover excellence and virtue to reward it", as is shown by the knighthoods he bestowed on Sir William Petty, the founder of the science of political economy, and the erudite Sir Thomas Browne.

The outstanding discoveries of Isaac Newton were recognized by William III, who appointed him master of the Mint in 1699, and by Queen Anne, who knighted him in 1702. All the four Georges encouraged science. George I is said to have boasted of his two subjects, pre-eminent in science, Newton in England and Leibniz in Hanover. Sir Hans Sloane, president of the Royal Society and of the Royal College of Physicians, the founder of the British Museum, collector and naturalist, was created a baronet by George I, and George II made him his first physician. George III solved the difficulties of the Corporation of Surgeons by establishing the Royal College of Surgeons by royal charter, discussed the *Philosophical Transactions of the Royal Society* with Dr. Johnson, and bestowed a baronetcy on Sir Humphry Davy. The King incorporated the Royal Society of Edinburgh by royal charter in 1784. Sir Joseph Banks, president of the Royal Society for forty-one years, acted as the King's scientific adviser; it was he who directed the dispatch of collectors abroad for enrichment of the gardens at Kew. In the establishment of the Royal Botanic Gardens there the Crown has promoted the studies of botany and horticultural science. On Banks's advice, the Linnean Society was given a royal charter in 1802. George IV was liberal to science. In 1825, he founded two gold medals to be awarded annually by the President and Council of the Royal Society for important contributions to science. These medals have been continued by his successors. The King also granted a supplementary charter to the Royal College of Surgeons in 1822, and gave the site at a nominal rent for the new College of Physicians in Pall Mall, opened in 1825. In 1826, largely through the influence of Dean Buckland, the Geological Society was incorporated by royal charter.

It is, however, in the Victorian Age that science reached a position of fame and authority. This progress was achieved through the great discoveries made by Owen, Darwin, Wallace, Huxley, Lister and others; but the opposition and hostility the claims of science might have aroused were overcome or silenced by the support they received from Queen Victoria and the Prince Consort. Elected chancellor of the University of Cambridge in 1847, Prince Albert established the Natural Sciences Tripos in 1848, which gave a notable impetus to study and research. Aided by Prof. Owen, he urged a similar departure on Oxford which was soon afterwards followed. He initiated the Great Exhibition of 1851, which displayed the wonders of applied science to the public, and the invested profits of which supply grants to students of science to this day. The Prince's influence was available in every movement for promoting the interests of art and science, for developing the education and improving the material welfare of the nation. After his death, Queen Victoria continued his work.

This royal encouragement of science was promoted by the Queen's successors. King Edward VII was especially interested in social welfare, in the prevention of tuberculosis, and in medical research. King George V followed in his footsteps, although his modesty prevented him from accepting the presidency of the British Association, which King Edward VIII, when Prince of Wales, accepted, giving an admirable presidential address at Oxford in 1926. King George VI throughout his heroic reign encouraged science, and one of his last public acts was to open the new laboratories of the Medical Research Council at Mill Hill. Queen Elizabeth II has already shown her interest in science by accepting the fellowship of the Royal Society; and the Duke of Edinburgh, alike as president of the British Association at Edinburgh in 1951 and by his acceptance of the membership of other learned societies, shows an equal appreciation of the value of scientific work in this atomic age when so many new fields of endeavour open out before it.

That for centuries the natural sciences have received unfailing support from successive rulers of the United Kingdom has helped to smooth the onward path of those "who search out and study the secrets of Nature by way of experiment".

# THE ADELIE PENGUIN

By Dr. W. J. L. SLADEN

Falkland Islands Dependencies Scientific Bureau, London, and Edward Grey Institute of Field Ornithology, University of Oxford

THIS summary of the breeding routine of the Adelie penguin (*Pucheramphus adeliæ*) differs in many respects from what has been written before. A full account of the work is in preparation (to appear in the forthcoming series, F.I.D.S. Scientific Reports). The study was made during two breeding seasons at Hope Bay, Graham Land, 1948–49, and Signy Island, South Orkneys, 1950–51, while serving with the Falkland Islands Dependencies Survey. The rookeries at Hope Bay and Signy exceeded 50,000 and 10,000 nests, respectively.

Evidence for the conclusions in this paper have been provided chiefly from marked and dissected birds. Approximately 1,300 Adelies were temporarily marked with paint, 338 banded with aluminium rings, many of which were also painted, and more than 800 dissected. The methods of marking penguins, including a new method using flipper rings, have already been described[1]. The large number of dissections was possible only because our 20–60 sledge-dogs, when at base, had to be fed on seal or penguin meat. Particular care was taken to cause no unnecessary waste of life.

## Suggested Age-Groups

Adelies live among the pack-ice during the winter, returning to rookeries on land to breed during October–February. At Signy, in 1950, adults started to return during the first week in October; but the largest population was not counted until the first week in November (Fig. 1). Eggs were first seen on October 29, and fresh eggs were still being found on November 19, this variation and other differences in breeding efficiency being due, not only to variation among individuals, but also to age and breeding experience. I therefore propose to divide the population at the rookery into the following four provisional groups, hoping that it will be possible to confirm the first three later by studying birds of known age.

### 'Experienced' or 'Established' Breeders

These are probably four or five years old and more and have had at least one, and probably two, years breeding experience.

*Successful breeders.* Ten pairs of breeding Adelies were ringed at marked nests at Hope Bay in November 1946[2]. In 1948–49 twelve returned to the nest-sites where they had been originally ringed, and five of the original pairs were still intact. Two more were found at adjacent nests in November 1947 and again in November 1948. The remaining six were not found. These results suggest that established pairs return each year to the same place and keep the same mates. Their behaviour also suggests that they can locate their old sites even under snow and can recognize their mates from the previous season.

The partners return from their winter quarters within a few days of each other; but if one of a pair comes back first, it will often keep company with another bird of the opposite sex until its true mate returns. A flight, male versus male or female versus female, may ensue in which the true mate usually wins. Should the mate of an established bird fail to return, the pair-bond may be established with its new partner.

Once arrived at the rookery, it was very rare for a breeding Adelie, either male or female, to return to sea until the nest of stones had been built and two eggs laid in it. During this period of about three weeks the pair were together; but as soon as the last egg had been laid, the female departed to sea to break her fast, leaving her mate to incubate alone. This normal routine (in which the sex of the males was confirmed by more than fifty dissections) could be upset by human or dog interference. Thus, if the male was killed before the female departed, she continued incubating for a few days but ultimately deserted when her weight dropped below about 3·5 kgm.

The male did not leave the rookery until his mate returned about two weeks later. While away, she regained most of the weight lost during her fast. Average fasting periods of seven marked males and females showed that the males fasted at least forty days, the females twenty-one (Fig. 2). A continuous fasting period of forty days by a bird is exceeded only by the male emperor penguin (*Aptenodytes forsteri*), which fasts for sixty days during incubation[8].

The weight of the females fell from 5–5·5 kgm. to about 3·5 kgm. and their blubber from 6–7 mm. thick to nothing. The males, starting at a higher level of 5·5–6 kgm., lost weight more gradually, reaching about 3·5 kgm. after their fast, when their blubber had diminished from 7–8 mm. thick to nothing. Males were at sea for about two weeks and came back, having regained most of their lost weight, to relieve the females on the eggs, who left again for a short period. When they returned, the eggs were usually hatched or hatching (early and mid-December). The average incubation period was thirty-six days.

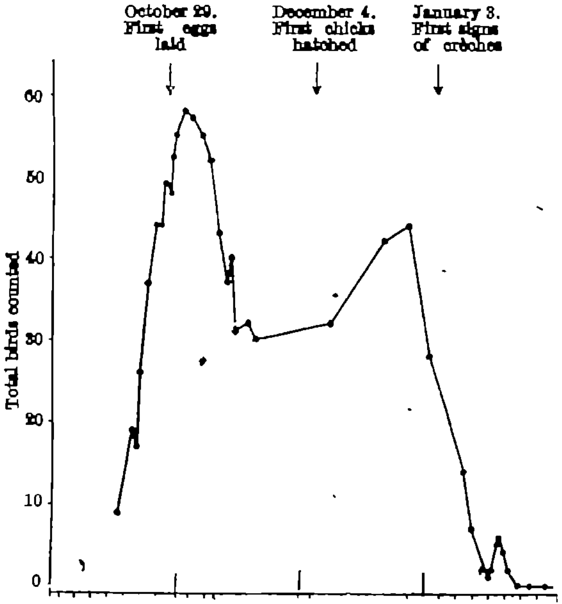

Fig 1. Population of a small colony at Signy Island, 1950–51, to show typical fluctuations during the breeding season

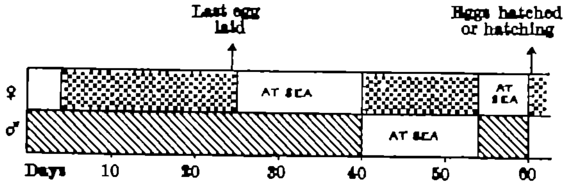

Fig. 2. Diagrammatic nest-history up to hatching of eggs made from the averages of seven males and seven females ringed at Signy Island on October 17 and 18, 1950. (Note: the first birds observed back at the rookery were seen on October 8, so the first fasting periods may be slightly longer than stated.) Male fasting periods at nest (hatched); female fasting periods at nest (dotted)

The parents shared care and feeding of chicks until they were large enough to be left alone. 'Crèches' were then formed in which the chicks congregated together in groups of a hundred or more, presumably for additional protection from the skuas (*Catharacta skua*). By marking birds during both years of study, it was found that parents recognized and fed their own individual chicks. The young left the rookery independently of their parents when they had lost their down, about two months after hatching.

*Unsuccessful breeders.* If the eggs were lost, the nest was deserted; but it was usually re-occupied between the time when the chicks of other pairs were hatching and crèche formation. The second peak in the population curve (Fig. 1) during December is partly due to this return of unsuccessful breeders. Nests were rebuilt, the original pair-bond (at least in 'experienced' birds) was almost certainly maintained, and the usual behaviour patterns (including copulation) seen in the pre-egg stage were observed again, though on a reduced scale. No second clutch was laid, though there was a noticeable enlargement of the gonads. The male was more faithful to his nest territory than his mate and often came back earlier and remained longer, usually alone, at his pile of stones. These unsuccessful breeders have been mistaken by previous writers for 'parent guards' of the crèche, a function they do not perform.

## 'Inexperienced' or 'Unestablished' Breeders

These are probably three or four years old and breeding for the first, or perhaps the second, time. Their behaviour differs somewhat from that of the 'experienced' birds, though with some overlap due to individual variation. They often arrive back later and take up territories on the periphery of the colonies, or fill vacant places within them. They are the cause of most of the fighting. Courtship behaviour is more prolonged, egg and chick mortality higher, breeding efficiency lower. Thus Fig. 3 shows a badly built nest on a rock slab. The male is beside his mate, who has inadvertently scraped away the egg with her feet. Sheathbills (*Chionis alba*) are waiting near by. Such eggs fall an easy prey to these scavengers, which pay more attention to badly looked-after nests than to those of 'experienced' birds.

## Non-breeding 'Wanderers'

These two- or three-year-old birds wander around the rookery in small parties and even visit rocky outcrops 1,000 ft. above sea-level far away from the breeding area. Some of them build poor nests or

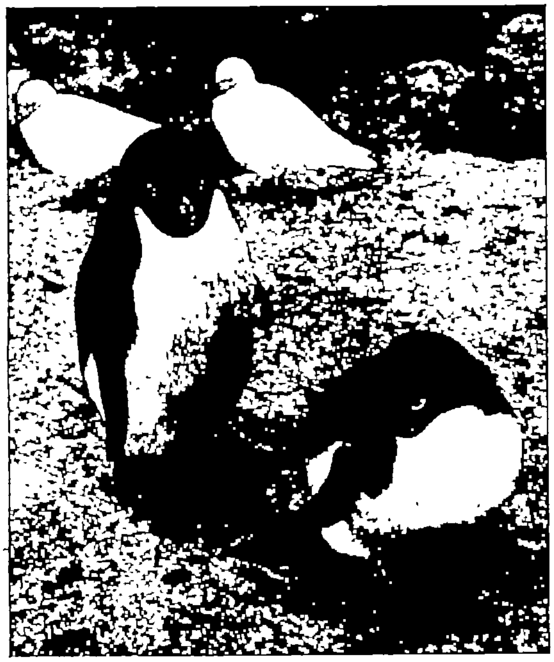

Fig. 3. 'Inexperienced' breeders. Sheathbills (*Chionis alba*) waiting behind in hope of securing egg

occupy vacant sites for a short time before moving elsewhere or being turned out by older birds. A proportion of these 'wanderers', when dissected, showed undeveloped gonads despite their adult plumage. It is this age-group, together with some of the 'inexperienced' birds, that, under favourable conditions, will establish themselves in new ground and thus extend the range of the species.

### Birds in Immature Plumage, or Yearlings

These are last season's young, easily recognized by their white throats. This immature plumage is carried for twelve months and moulted in February. They normally live among the pack-ice, but are occasionally seen at the rookery, where they associate with the 'wanderers'. Several were seen building nests in a half-hearted way on the periphery of a colony; but, like the 'wanderers', they never stayed in one place for long.

### Individual Recognition

The problem of individual recognition is fundamental in interpreting the behaviour of breeding Adelies. Undoubtedly the two birds of a pair recognize each other from the time they are paired, before egg-laying, up to the time when the chicks go into the crèche. Previous literature summed up by Murphy[4] suggests that the pair-bond among adults is not maintained in subsequent seasons and that it is unlikely that the parents recognize their own offspring once the crèches have been formed. In their two papers on the Adelie, Sapin-Jaloustre and Bourlière[5,6] do not contradict this. Richdale[7] has, however, shown that the yellow-eyed penguins (*Megadyptes antipodes*) recognize each other as individuals.

In 1948–49 I placed coloured rings around the flippers of the chicks of marked parents before they went into the crèches and discovered that the parents found and fed their own offspring when in the crèche. Andrew and Roberts[8] have shown that adults return to the same nests and maintain the same pair-bond, and I believe this pair-bond is maintained, not merely because they return to the same nest-site, but because they recognize each other as individuals, even after a winter among the pack-ice.

Three important factors enter into this recognition: territory, visual and auditory recognition, and the so-called mutual display. Territory brings both members of a pair, and parents feeding chicks, back to known ground. A few chicks moulting their second down were marked and transferred to another crèche still within view of their own area but a quarter of a mile away. Most were back within twenty-four hours. But the actual nest-site is less important than visual recognition, since, though chicks may move out of a crèche and lie in their old nest-site when hungry, a parent is still able to recognize its chick should it be in a crèche several yards away.

Field experiments also showed that parents adopted chicks from other nests if small, but very rarely ones that were large enough to stand up. I believe that visual recognition is perhaps the most important single factor, being slowly acquired during the early stages of chick growth and fully developed by the time the chicks move into the crèche. Similarly with members of a breeding pair: the 'experienced' breeder may keep company with another bird, but be re-united to its true mate should the latter return to the nest later. Further, in at least three cases, a pair shifted their nest-site and yet remained together.

In the mutual display two birds stand facing each other and sway their necks from side to side with bills pointing upwards and flippers close to the side. The display may be 'loud' or 'quiet', when loud being accompanied by much noise with bills wide open, whereas in the quiet mutual display there is less neck movement and a soft 'squaw' with closed bill (Fig. 4) or no sound. The mutual display was seen most frequently before the eggs were laid, during nest-building; but was repeated each time one of a pair returned from the sea to take over incubation, or feeding duties, before the crèches were formed. The

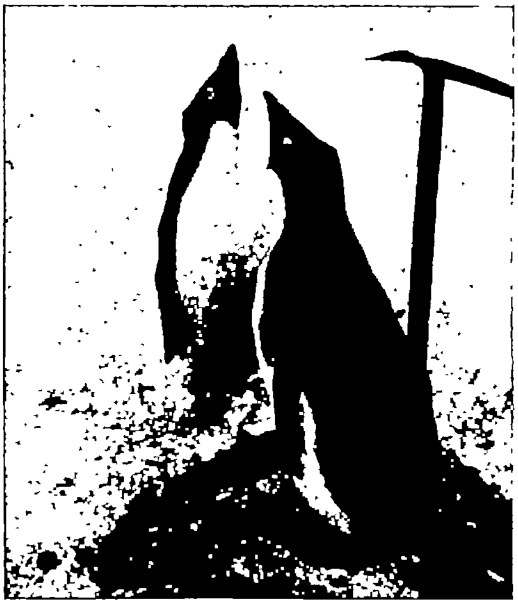

Fig. 4. The 'quiet' mutual display between a pair of adults at their nest. The ice-axe by the nest is for scale

bird returning from the sea comes straight to its nest. Their usual behaviour and directness of purpose suggest they recognize their mates from a distance. The loud mutual display follows immediately they meet and is repeated several times, followed by the quiet display. There is usually a recrudescence of the loud display when the incubating bird walks off the eggs or chick and the new arrival takes its place.

A small chick at first pays little attention to this noise and movement, but soon begins to associate it with a fresh supply of food. As it grows bigger, its simple piping changes into a quivering call which has the same pattern as the sound made in the loud mutual display and is, as a large chick, accompanied by the same movements as seen between two adults (Fig. 5). The display and change of voice are well developed between parent and chick by the time the chick goes into the crèche and are repeated between parent and chick each time the parent returns with food. I therefore believe the most important function of the mutual display and call to be a confirmation of visual recognition. The parent probably recognizes its chick with greater certainty than the chick its parent. I have seen marked chicks pestering different parents for food ; but have only once seen a marked parent feeding a marked chick not its own, and then for one brief and harassed mouthful, after which its own chicks, which were smaller, received the food.

Once it is established that adult pairs, and parents and chicks, recognize each other, it seems reasonable to suggest that this flightless bird, less than two feet in height, is helped in finding its way to its nest in the crowded rookery by recognizing its neighbouring adults.

## The Ecstatic Display

The other most prominent display of the Adelie is the so-called 'ecstatic', originally described by Wilson[8] and Levick[9] and admirably re-described by Sapin-Jaloustre and Bourlière[6]. A subsidiary stage of this display appears to have been missed by previous writers.

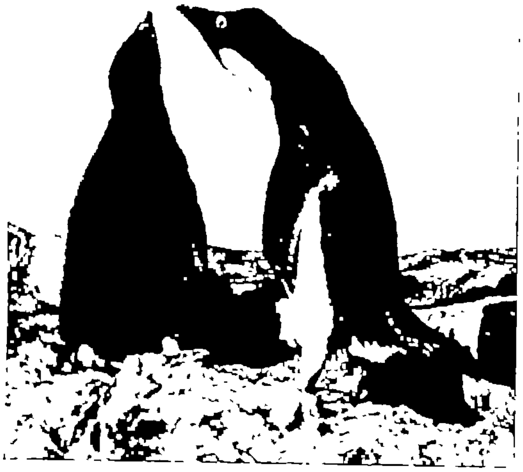

Fig. 5. The 'quiet' mutual display between a chick and parent on return of the parent from the sea with food

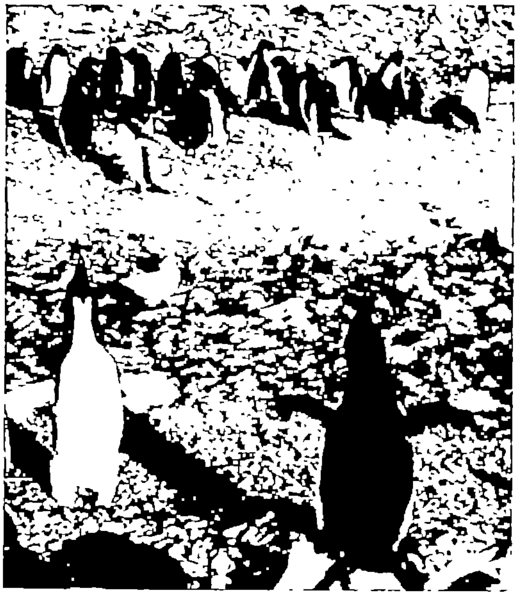

Fig. 6. Two Adelies in the ecstatic display alone in their nests

In the main display, with bill pointing upwards, the bird stretches to its full height and, beating its flippers backwards and forwards, emits a characteristic guttural throbbing sound (Fig. 6). The display is often contagious, but is not taken up by all the birds in a colony. It was seen most often early in the season and more among the unpaired 'inexperienced' and 'wanderer' males, particularly when attempting to establish themselves, than among the paired 'experienced' breeders. A sample of nearly a hundred dissected birds showed that the display was confined to the male up to the time when the chicks had, or should have, hatched, but thereafter was found in both sexes. I never saw two birds in one nest both in the ecstatic display. If the male displayed, the female by his side usually went through the same motions as seen in the quiet mutual display. A lone male standing in his nest would often by this display attract a 'wanderer' or 'inexperienced' or even an unsuccessful female to his side, and I consider its most important function to be in pair formation. When seen, less commonly, in lone marked birds incubating eggs or standing over chicks, it often appeared to be associated with stress.

In the subsidiary display, usually seen in lone birds before or immediately after the main display, or as a separate display, the bird rocks its head from side to side with bill directed either to the left or right axilla. The flippers continue to beat rhythmically backwards and forwards as in the main display. A soft "*gurr-gurr-gurr-gurr-gurr*" accompanies these movements which is characteristic of this particular display. Its function is, at present, obscure.

# NEWS and VIEWS

## Prof. W. Pauli, For.Mem.R.S.

Prof. Wolfgang Pauli, who has just been elected a foreign member of the Royal Society, is best known for the exclusion principle, or 'Pauli principle', which he formulated in 1925, and which at once cleared up many unexplained features of atomic structure and atomic spectra. This principle, which states that no two electrons, or nucleons, can be in the same quantum state, is logically independent of the other laws of quantum mechanics. It applies to all elementary particles of half integral spin, and Pauli himself showed in a later investigation that a system in which such particles did not obey the principle, or in which it applied to photons or other particles of integral spin, could be described without logical contradictions, but would lead to physically unreasonable consequences. Besides the work on the exclusion principle, for which he was awarded the Nobel Prize for physics in 1945, Pauli has made many important contributions to theoretical physics, beginning with an article on the theory of relativity, which he wrote while he was a research student, simultaneously with his thesis on the quantum theory of the hydrogen molecule ion, and which has remained until now the standard text on the subject. He initiated the modern electron theory of metals by applying the exclusion principle, extended by Fermi to the statistic of many-particle systems, to the paramagnetism of metals. More lately he has contributed to the theory of mesons, and he has always been interested in a clear formulation of the basic concepts of quantum theory. His enthusiasm and insistence on fundamentals have inspired many collaborators and pupils, and by incisive criticism he teaches them to beware of loose thinking.

## Technical Assistance to South and South-East Asia

The report for 1952 of the Council for Technical Co-operation in South and South-East Asia (pp. 16 ; London : H.M.S.O., 1953 ; 6d. net), which deals with the technical co-operation scheme of the Colombo Plan, indicates a marked increase in the flow of technical assistance over that for 1951 ; 90 experts and 538 training places were provided, as against 45 and 309, respectively, in 1951, but the limiting factor remains not the availability of funds, but the willingness of individual experts to accept appointments overseas. The increasing world-wide demand for technologists, and full employment in the supplying countries accentuate the problem, and improvement is due chiefly to improved administrative arrangements, to the maintenance of a sense of urgency in meeting the needs of under-developed countries and to the way in which the idea of the Colombo Plan has caught public imagination. Most of the experts provided during the year were engaged for specific projects where their duties included the training of local personnel as well as some measure of executive responsibility for the scheme, but the demand for experts whose main duties will be training local personnel is increasing. Schemes which combine capital and technical assistance have also increased. Ceylon, India and Pakistan have taken 118 of the 135 experts so far supplied and sent 689 of the 847 trainees. They have also supplied five of the experts and facilities for fifty-seven trainees. The United Kingdom has provided 67 experts and 279 training places in all, the corresponding figures for Australia being 40 and 286, for Canada 6 and 106, and for New Zealand 17 and 119. The demand for, and provision of, equipment for use by experts and for training and research institutions also increased ; but although the sums involved are considerable, by December 31, 1951, only £400,000 out of the eight million pounds set aside for the Scheme had actually been committed, and in April 1952 it was agreed that the scheme should be co-terminous with the Colombo Plan and operate until June 30, 1957. The assistance provided has been mainly in the fields of medicine and health, agriculture and forestry, engineering, industry and trade, and transport and communications. In addition, the United Nations and the Specialist Agencies have provided the area with 502 experts and 564 trainees, and the corresponding numbers supplied by the United States are 210 and 403.

## Universal Copyright Convention

The text of the Universal Copyright Convention which was signed at Geneva last September by the delegates of thirty-six countries, including the United States and the United Kingdom, has now been published by the United Nations Educational, Scientific and Cultural Organization (pp. 24 ; 125 francs, 2s. 6d. or 50 cents. Paris : Unesco ; London : H.M.S.O., 1953). The Convention seeks to supplement existing copyright conventions, such as the Berne Convention, to which some forty countries (but not the United States or any Latin American countries, except Brazil) are parties. Ratification of the Convention by the United States and by Britain would greatly facilitate the obtaining of copyright protection in the United States for the work of British authors. At present, works in the English language can only secure protection in the United States if, in addition to registration at the Copyright Office in Washington, D.C., they are printed in the United States from type set up in that country. Under the Universal Convention, however, a country which requires compliance with formalities as a condition of obtaining copyright agrees to regard such conditions as satisfied, so far as works of foreign origin are concerned, if such works bear the symbol 'C' written in a circle, indicating that copyright protection is claimed, together with the name of the copyright proprietor and the year of first publication. This provision will facilitate the protection of British works, both in the United States and in many other countries outside the Berne Convention, where registration is often required as a condition of copyright protection. In other respects, works will be protected in each contracting country in accordance with the domestic law of that country, but no country will be required to give a longer term of protection than that to which a work is entitled in its country of origin. The Convention will come into force when ratified or formally accepted by twelve countries, of which at least four are not parties to the Berne Copyright Convention.

## Planetary Influences on the Sun

A paper entitled "Planetary Influences on the Sun", by M. Kopecký, P. Mayer and V. Borovičková, of the Central Astronomical Institute, Ondřejov (*Bull. Cent. Astro. Inst. Czech.*, 3, No. 3 ; 1952), contains the results of their work on sunspot activity and the positions of the planet Mercury. In a previous paper (2 ; 1950) certain results were given by the same authors on the planet Venus, and it was found that the period of variation of the relative number was approximately equal to the synodic rotation of the sun with reference to the planet. Owing to the comparatively large eccentricity of the orbit of Mercury, perihelion and aphelion conjunctions are dealt with separately, and the material was reduced to those conjunctions for which the most outstanding effects would be expected: these are at inferior conjunction when both the earth and Mercury are in perihelion; and at superior conjunction when Mercury is close to perihelion and the earth to aphelion. Next, the results were analysed for the least favourable conditions, that is, when Mercury is in aphelion and the earth also in aphelion at inferior conjunction and when Mercury is in aphelion and the earth in perihelion at superior conjunction. The results are shown by a number of curves, but the correlation between the sunspot-characteristic and the synodic revolution of Mercury is not so well defined as in the case of Venus. It is suggested that this may be due to the large eccentricity of Mercury's orbit, which makes the statistical results more difficult, or to a smaller hypothetical influence of Mercury. Nevertheless, analogical forms of the curves of sunspot-characteristics for Mercury as for Venus have been obtained, and it is possible to assume that Mercury has an influence in the production of sunspots.

### Rock Engravings in the Kilimanjaro Area

In the November and December numbers of *Man* there is an important article by H. A. Fosbrooke, sen., a sociologist of Tanganyika Territory, and Petro I. Marealle, chief of the Vungo division of the Chagga tribe, on the engraved rocks of Kilimanjaro and their meaning and use in initiation ceremonies. Rocks covered with apparently meaningless engraved lines are known from many parts of Africa. It is not suggested that the explanation given for the ones of Kilimanjaro applies in all cases; but it may well be that the others were used for some analogous purposes. In the November number, Fosbrooke describes the engraved rocks and supplies a couple of pages of excellent illustrations. In the December number, Marealle describes the use and explanation. "From the body of the youths of the age set are chosen 12 who are the children of people of importance. . . . The stone itself is engraved thus. The elder who is the instructor goes with the 12 youths to the stone. He wears a ring of hide, and says to them 'you see this stone and its engravings: look this is your whole country. The youths of old who made these marks were led by an elder who like myself knew much wisdom'. . . . Then the elder gives one of the 12 a little axe and shows him how to cut a line on the stone. The youth cuts a small mark from two to six inches long." Thus the rocks become more and more covered with engraved lines apparently meaningless. The ceremony, of course, continues, but enough has been quoted to give the gist of the explanation. This seems to be the first time such an account of such a ceremony and of the reason why these rocks get covered with engraved lines has ever been given; and it is factual, given by a man who formerly was an instructor, and is not an explanation produced out of the fancy of a psychological anthropologist.

### High-frequency Electric and Magnetic Shielding

The third monograph of the series issued by the Research Institute of Applied Electricity, Hokkaido University, Sapporo, Japan, is entitled "Some Researches on High-Frequency Phenomena and Electrical Direct Heating" (Monograph Series No. 3; pp. 105; 1952) and contains four papers, two of which deal with the important problem of electrical shielding of high-frequency apparatus. In the first of these, Y. Asami, the director of the Institute and editor of the monograph series, and A. Matsumoto discuss in general terms the various sources and methods of suppression of electromagnetic leakage in high-frequency apparatus and then consider theoretically the principles of electric and magnetic shielding. They follow this by a description of a number of experiments performed with special care to detect the defects of apparatus made in Japan, and it is concluded that radio interference from high-frequency apparatus can be almost eliminated by application of the suggestions made. It is emphasized that, as some kinds of wire-nettings used for screening are subject to rapid deterioration, good netting resistant to deterioration must be selected and used. The second paper, by T. Matsumoto, is a continuation of the one, on the theory of electromagnetic shielding by a shielding room of wire-netting, which appeared in No. 1 of the series. Several fresh problems are briefly considered: the effects of finite dimensions of the current-loop wave source, and of the eccentricity of its position relative to the centre of the shielding room; and the theories of double shielding formed by two concentric spherical walls of wire-netting, and of shielding by a shielding room consisting of a cylindrical cavity with perfectly conducting walls and with a wire-netting bottom.

### Seasonal Variation in the Reproductive System of Garter Snakes

Although many papers have been written, there is still much that is not understood concerning the external and internal factors responsible for the cyclic nature of reproduction in reptiles. Investigations of the seasonal fluctuations in various parts of the reproductive system of several species of lizards, snakes and turtles have revealed interesting species differences. For a more complete understanding of reptilian reproduction it would appear that detailed descriptions of the seasonal changes of many species are desirable (*J. Morph.*, 90, No. 3; May 1952). Such a study was carried out by Wade Fox on the common garter snake (*Thamnophis*), several species and subspecies of which could easily be obtained throughout the year in the vicinity of San Francisco Bay. These investigations showed that the gonads of the male garter snake, *Thamnophis elegans terrestris*, exhibit marked seasonal variation. The testes begin to increase in size in the early spring, reach their maximum size and weight in late July, decline in the autumn, and are of minimum size during the winter months. These macroscopic fluctuations are accompanied by corresponding histological changes.

### Collections of British Birds and Eggs

In the March number of the *Museums Journal* Mr. Colin Matheson (National Museum of Wales) has performed a useful service in that he has collated much information regarding the present location of museum collections of British birds and eggs. In order to add to the value of such notes, he has included collections which are known to have been destroyed during the Second World War. Changes in outlook, as well as in economic and social conditions, make it unlikely that many more large collections will be formed, and hence it is important that ornithologists should know the whereabouts of the material available for study.

## Technical and Technological Education in Britain

In his presidential address to the Association of Teachers in Technical Institutions, delivered at Leeds on May 24, Mr. C. L. Bott, principal of Southport Technical College, referred to the lack of progress in secondary technical education in Britain, and to the need for careful thought as to what exactly the secondary technical schools are intended to do. Mr. Bott visualizes them as catering for three groups of students: a few who would proceed to a university or college of technology; those of a less academic type who require the stimulus of a more practical type of training; and those who would ultimately be trained as technicians. He emphasized the necessity for effective and continuous education from the secondary technical schools whether to a university or to a technical college, but he made the surprising remark, in view of what has been said, for example, at recent conferences of the Federation of British Industries, that firms now find difficulty in training workers themselves and look more and more to the technical colleges. He also commended the provision of sandwich courses: both education and industry are convinced, he said, that such schemes could ensure a sound integration and correlation of works and college training, and he thought that the scope and number of such schemes could be extended with advantages both to students and the community as a whole. In his reference to higher technological education, Mr. Bott was less happy, pursuing the chimera of a national award, which the Government has wisely rejected; he passed over the vital questions of adequate resources and conditions which will attract staff of high calibre, both of which are essential to enable the technical colleges to contribute significantly to the supply of technologists. Nor did he distinguish clearly between technician and technologist, or discuss the importance of an appropriate numerical balance between the two.

## National Research Council of Canada: New Members

Three new members have been appointed as follows to the National Research Council of Canada for a three-year term ending on March 31, 1956: Dr. R. F. Farquharson, Sir John and Lady Eaton professor of medicine and head of the Department of Medicine, University of Toronto; Dr. E. G. D. Murray, professor and chairman of the Department of Bacteriology and Immunology, Faculty of Medicine, McGill University; Dr. David L. Thomson, dean of the Faculty of Graduate Studies and Research and chairman of the Department of Biochemistry, McGill University. In addition, the following three members, who have already served one term on the Council, have been reappointed for another three years: Dr. C. W. Argue, dean of science and professor of biology, University of New Brunswick; Dr. A. G. McCalla, dean of agriculture, University of Alberta; Dr. G. M. Shrum, professor and head of the Department of Physics, University of British Columbia. The National Research Council consists of a president, two vice-presidents and seventeen members. The members serve in an honorary capacity for a three-year term which may be renewed once; they are appointed by Order-in-Council and are chosen to represent the universities and industry, the selection being made in such a way as also to provide adequate geographical representation.

## Colonial Service: Recent Appointments

The following appointments have recently been made in the Colonial Service: N. R. Fuggles-Couchman (agricultural officer, Tanganyika), regional assistant director of agriculture, Tanganyika; W. B. Mason (senior agricultural officer, Gold Coast), assistant director of agriculture, Gold Coast; W. V. Rose (agricultural officer, Nyasaland), deputy director of agriculture, Barbados; F. E. Hughes (conservator of forests, Gold Coast), deputy chief conservator of forests, Gold Coast; H. S. H. Watson (senior assistant conservator of forests, Northern Rhodesia), deputy conservator of forests, Northern Rhodesia; A. T. Crow (geologist, Gold Coast), senior geologist, Gold Coast; F. H. Fitch (senior geologist, North Borneo), deputy director of geological surveys, North Borneo; E. G. Davy (assistant director of observatory, Mauritius), director of observatory, Mauritius; E. G. B. Jones (agricultural instructor, British Guiana), agricultural officer, Jamaica; Miss C. McGlade (clerk, grade I, Statistical Department, East Africa), statistician, Statistical Department, East Africa; J. C. Williams (engineering surveyor, Water Development Department, Tanganyika), topographer, Department of Geological Survey, Uganda; S. J. A. Williams, agricultural officer, British Honduras; J. Armour, veterinary officer, Nigeria; N. St. G. Hyslop, veterinary research officer, Kenya; W. P. Unsworth, veterinary officer, Department of Agriculture, Trinidad; C. S. Eastman, assistant conservator of forests, Nigeria; M. Garstang, assistant meteorologist, British Caribbean Meteorological Service, Trinidad; V. E. Sills, biochemist, Agricultural Department, Fiji.

## Physical Society: Officers

At the annual general meeting of the Physical Society held on May 15 the following officers were elected: *President*, Prof. R. Whiddington; *Honorary Secretaries*, Mr. C. G. Wynne and Dr. H. H. Hopkins; *Honorary Treasurer*, Mr. A. J. Philpot; *Honorary Foreign Secretary*, Prof. E. N. da C. Andrade; *Honorary Librarian*, Dr. R. W. B. Pearse; *New Members of Council*, Prof. P. M. S. Blackett, Prof. N. Feather and D. W. Fry.

## Fourteenth International Congress of Zoology

The Fourteenth International Congress of Zoology will take place in Copenhagen during August 5–12, and more than five hundred zoologists from forty-four countries outside Denmark have already indicated that they will be present. The president of the Congress will be Dr. R. Spärck, professor of zoology, University, Copenhagen, and the secretary-general, Dr. Anton Fr. Bruun, Zoological Museum of the University, Copenhagen. Those who wish to become members of the Congress are invited to apply to the Secretariat, Krystalgade 27, Copenhagen K, Denmark. The membership fee is 100 Danish kroner (about £5). Associate membership costs 50 Danish kroner, but does not entitle the member to receive the proceedings of the Congress. Accommodation may be arranged through any travel agency, and the secretariat is also prepared to arrange hotel accommodation for members but applications should be made as early as possible. A preliminary list of twenty sections of zoology has been suggested, so that it will be possible for members to meet their colleagues in fairly restricted fields, but more sections may be established depending upon the communications offered by members. Zoologists wishing to be present at this Congress should make application through their bankers on Form *T.2* for special allotment of exchange for the purpose of attending the Fourteenth International Congress of Zoology.

## The Night Sky in June

NEW moon occurs on June 11d. 14h. 55m., U.T., and full moon on June 27d. 03h. 29m. The following conjunctions with the moon take place: June 8d. 08h., Venus 8° S.; June 13d. 07h., Mercury 0·1° N.; June 21d. 16h., Saturn 8° N. In addition to these conjunctions with the moon, Mercury is in conjunction with Mars on June 2d. 10h., Mercury being 1·0° N. Mercury is an evening star, setting at 21h., 21h. 55m. and 21h. 35m. on June 1, 15 and 30, respectively. Venus, a morning star, rises at 2h. 20m., 1h. 55m. and 1h. 30m. at the beginning, middle and end of the month, respectively; the stellar magnitude of the planet averages − 0·4, and the visible portion of the illuminated disk varies from 0·36 to 0·54. Mars is an evening star, setting at 21h. at the beginning of the month, but, as it is gradually drawing closer to the sun, it is badly placed for observation during June. Jupiter, a morning star, rises about the same time as the sun on June 1, and at 3h. and 2h. 10m. on June 15 and 30, respectively, but will not be favourably placed for observation until later than the middle of the month, when it can be seen in the constellation of Taurus. Saturn is visible until the morning hours, its times of setting on June 1, 15 and 30 being 2h. 10m., 1h. 20m. and 0h. 20m., respectively, and it can be seen a little north of Spica during this time. No occultations of stars brighter than magnitude 6 take place in June. Summer solstice occurs on June 21d. 17h.

## Announcements

PROF. IRENE MANTON, professor of botany in the University of Leeds, has been elected an honorary member of the Danish Academy of Sciences and Letters.

SIR ERIC RIDEAL, professor of chemistry in King's College, University of London, has been appointed chairman of the Advisory Council on Scientific Research and Technical Development of the Ministry of Supply in succession to Sir John Lennard-Jones.

MR. J. T. SAUNDERS, secretary-general of the Faculties in the University of Cambridge, and formerly lecturer in zoology in the University, has been appointed principal of University College, Ibadan, in succession to Dr. Kenneth Mellanby.

THE Council of the Royal Society has appointed Mr. A. S. Laughton, of King's College, Cambridge, to be John Murray travelling student in oceanography and limnology. Mr. Laughton will carry out research on the physical properties of sediments, part of the work being carried out at the Lamont Geological Observatory, Columbia University, New York, during 1954.

THE following changes in the University of Sheffield have recently been announced. *Appointment:* Dr. A. F. Ruston, senior lecturer in pure mathematics. *Resignations:* D. K. Roberts, lecturer in mechanical engineering and sub-warden of Ranmoor House; R. M. Haythornthwaite, lecturer in civil engineering; Dr. K. Burton, lecturer in biochemistry; and F. Newby, information officer and librarian to the Department of Glass Technology.

THE Oliver Memorial Fund is offering an award worth £50 to a British subject for original work or services in connexion with research, organization or the donor aspect of blood transfusion. Applications or information directing attention to suitable candidates must be submitted before August 31 to the honorary treasurer of the Fund, F. W. Mills, c/o National Provincial Bank, Ltd., Holborn Circus, London, E.C.1.

A CONTINUATION of the seminar on polymer science (cf. *Nature*, 171, 65; 1953) will take place on June 29; a programme and abstracts of lectures can be obtained from the Chemistry Department, University College, London, W.C.1.

THE Royal Microscopical Society will hold a conversazione in its rooms at Tavistock House South (Entrance *D*), Tavistock Square, London, W.C.1, during June 9–10 (7.30–10 p.m.) in honour of the Coronation of H.M. the Queen, Royal Patron of the Society. The conversazione will comprise demonstrations illustrating the development of the microscope and the advances in microscopical technique made from the time of the granting of the Royal Charter by Queen Victoria to the present day. The exhibition will be open to the public during June 11–12.

THE Institute of Physics has awarded Bowen Prizes of fifteen guineas each to the following for their papers published in the *Journal* of the Institute: G. T. Wright, University of Birmingham (a single-channel pulse-height discriminator of high speed and stability); G. D. Dew, National Physical Laboratory, Teddington (preservation of groove form in replicas of diffraction gratings); H. Aspden, Trinity College, Cambridge (measuring the magnetic permeability of rod specimens). These Prizes are provided by the Scientific Instrument Manufacturers' Association of Great Britain, Ltd., from a fund established by the late Mr. William Bowen, and are awarded to persons not more than thirty-five years of age whose papers are judged to be the best in respect of originality, scientific value, practical utility to instrument makers and users, and presentation.

ON the recommendation of a joint committee of the Institution of Mining and Metallurgy and the Institute of Metals, Capper Pass awards have been made as follows for papers, the subjects of which are shown in brackets, published during 1952 in either the *Transactions of the Institution of Mining and Metallurgy* or the *Journal of the Institute of Metals*: E. Davis and S. G. Temple, jointly (batch and continuous annealing of copper and copper alloys), C. P. Paton (batch thermal treatment of light alloys), Dr. E. C. Ellwood and T. A. Henderson, jointly (formation and control of magnetite during copper smelting operations), P. M. J. Gray (production of pure cerium metal by electrolytic and thermal reduction processes) and E. A. Hontoir (determination of sulphur in iron pyrites). The awards are each for £50, except the last-named, which is worth £25. They are made annually from a sum of £200 given each year by the firm of Capper Pass and Son, Ltd., Bristol, and are intended to encourage the publication of papers on processes and plant used in extraction metallurgy, assaying and on processes and plant used in all branches of the non-ferrous metal industry.

# BIRKBECK COLLEGE, LONDON

## NEW BUILDING

AT three o'clock in the morning in the "Crown and Anchor" public house in the year 1823, Dr. Birkbeck was elected president of the London Mechanics' Institution, then and there founded. That institution has grown and thriven for more than a hundred years and still serves the student who has to pursue learning and earn his living at the same time. The adoption of the name "Birkbeck College" in 1907 symbolized the growing claim to university status, and the admission of the College as a School of the University of London in 1920 marked the accomplishment of ambitions which long existed among its teachers and students. In 1930 the Court of the University set aside part of the University site in Bloomsbury for a new building for the College, the premises in Fetter Lane of which, though referred to at their opening in 1885 as "spacious and convenient", had become quite inadequate.

In spite of generous benefactions from many sources, sufficient money was not accumulated until 1939 when the new building was started. However, operations had to be abandoned in 1940 with only the steel skeleton erected. Work was resumed after the War, and the hopes and labours of so many years culminated on April 28 when H.M. Queen Elizabeth the Queen Mother, patron of the College, visited the new building. In the presence of a distinguished gathering in the Senate House of the University, Her Majesty was welcomed to the College by the Master, Dr. J. F. Lockwood. The president of the College, the Right Hon. Lord Justice Denning, then invited the Queen Mother to declare the new building open. In her address, Her Majesty referred to the "absorbing story" of the College's development and to those whose enterprise turned what might have been a story of disaster into a record of triumph. "To you," she concluded, addressing the students, "we confidently look for the preservation and enrichment of our civilization."

Having unveiled a commemorative inscription in the entrance hall, Her Majesty inspected part of the new building. She was received in the Psychology Department on the fourth floor by Prof. C. A. Mace and Mr. A. Rodger. During the inspection of the Psychological Laboratory, Her Majesty was shown experimental studies on perception, learning, fatigue and other topics representative of the normal work of a psychological department. Among research activities in applied psychology displayed in the laboratory were an investigation into new methods of plotting the movements of aircraft, and the training of a blind worker by a blind instructor in skilled assembly work. A case study in vocational guidance was also in progress during the visit.

On the third floor, occupied by the Chemistry Department, Her Majesty was received by Prof. W. Wardlaw, Dr. D. J. G. Ives and Dr. D. H. R. Barton. She passed through the main teaching laboratory, with accommodation for ninety students, where she watched a practical class in progress, and spoke to some of the students.

The Queen Mother then inspected the library, which includes a particularly large and attractive reading room. Before leaving, Her Majesty took tea in the Council Chamber.

In addition to the Departments already mentioned, the new building houses the Departments of Physics (Prof. J. D. Bernal), Zoology (Prof. W. S. Bullough), Geology (Dr. A. T. J. Dollar), Botany (Prof. C. T. Ingold), Geography (Prof. W. G. East), and Mathematics (Prof. A. C. Offord).

The Faculty of Arts has accommodation for its staff in Malet Street; but most of its teaching is done in space kindly provided by neighbouring institutions.

Of the 214 degrees awarded to Birkbeck students during the session ending July 1952, forty were postgraduate. The facilities which are now available for research will make possible a wide extension of opportunities for students who wish to prepare for the higher degrees of the University of London.

---

# HUMAN PERFORMANCE

THE third symposium of the Ergonomics Research Society was held in the Department of Human Anatomy, University of Oxford, during April 13–16, the subject being "Human Performance, its Measurement and Limitations". The diversity of disciplines related to the study of the relation between man and the environment in which he works was well illustrated by the number of scientific departments represented; among the hundred and thirty members and visitors who attended were leading workers from many parts of the world, including, in particular, Scandinavia, Finland, Germany, the Netherlands and the United States. The deliberations fell into two main categories: those with a predominantly physiological approach to the efficiency of performance in hard manual work, and those of a psychological nature dealing with some of the lighter industrial work processes. The discussions revealed a clear realization of the complementary roles of these different methods of assessing human performance and the necessity of relating them realistically to the problems actually confronting the production engineer. They also indicated the gap that exists between fundamental work and the application of relevant results to industrial work.

In his opening address, the chairman, Prof. W. E. Le Gros Clark (Oxford), directed attention to the interplay of fundamental and *ad hoc* research on which successful ergonomic investigation depends. As long as the ergonomic research worker, stimulated by some practical problem, has the freedom to develop his interest in the more fundamental aspects, the subject can be regarded as a suitable one for university departments. Of the various difficulties attending such research, he stressed in particular the inadequacy of the present supply of human subjects for laboratory tests.

Sir Charles Lovatt Evans (consultant physiologist, Ministry of Supply), in an introductory address, dealt with the contributions which human physiology can make to the improvement of work and working conditions. Human physiology has reached a stage in its development where, generally speaking, it possesses the necessary basis of method and theory for the study of almost any physiological process which might be of interest in human activity—in industry, sport or war. He illustrated this by an account of the history of muscle physiology and showed how our present understanding of the anatomical, dynamic and energy characteristics of muscle action has been attained and can be employed in ergonomics. Dr. O. H. Wansborough Jones (chief scientist, Ministry of Supply) discussed ergonomics from the point of view of the user and posed a number of general questions for the consideration of the symposium. A distinction should be drawn between the 'all-out' character of war-time ergonomic and operational research and that of peace time, where the objective should be increased productivity without increased strain. Looking to the future, one should bear in mind the change that will come about with the virtual elimination of the human operator; it means that ergonomics will have to re-orientate itself increasingly to the problems of maintenance and transport. At the present time, said Dr. Jones, these are rather neglected. It is also not sufficiently appreciated that the duties of the administrator and executive officer present ergonomic problems, for this type of work is often done at very high pressure and inordinately long hours, particularly so in the higher posts in business and the Civil Service.

A number of the papers dealt with the physiological methods of work-study in the laboratory and the factory. Techniques for the continuous registration during exercise (on a bicycle ergometer with electrical braking-system) of ventilation-rate, oxygen consumption, carbon dioxide production and pulse-rate were described by Dr. F. H. Bonjer (Leyden). For the gas analyses he uses a Kipp diaferometer employing the Noyons principle whereby the composition of the gas mixture can be measured by changes in the electrical resistance of a heated wire. The cardiotachometer depends on photo-electric recording of fluctuations in the light transmission through the ear-lobe. The usefulness of estimations of heart-rate and metabolic cost in work study cannot be over-emphasized, and hence there is a great need of methods which can be used at the work bench. Special attention was devoted in a number of papers to the portable instruments devised at the Dortmund Max Planck Institute for these purposes, the Kofranyi–Michaelis respirometer and the Müller photo-electric pulsometer. The *K–M* respirometer was used in laboratory investigations described by Passmore at Glasgow to determine individual variation in metabolic cost of standardized stepping and walking. The reliability of this last-named instrument, even in the very difficult environmental circumstances of underground work, was proved by J. G. Durnin, R. C. Garry and R. Passmore in an investigation of the metabolic cost of a variety of coal-mining activities. The information obtained gave a picture of the daily pattern of work of underground miners, and comparisons could be made with findings in the Ruhr and other coal-fields. Dr. O. G. Edholm (London) showed how by keeping a detailed diary of the complete 24-hourly routine (as carried out on a group of military cadets), it was possible to obtain a reasonably accurate evaluation of the energy requirements of the group. In this investigation it was only necessary to make Douglas bag metabolic determinations for a few tasks and, by using figures obtained by other workers, the estimate (3,420 kcal.) was found to agree quite well with the calorie intake (3,700 kcal.) as determined by a dietary survey carried out simultaneously by Prof. R. A. McCance and Miss E. M. Widdowson.

The close relationship between the intensity of the work measured by the metabolic cost and the heart-rate during work indicates the value of the pulse-rate as an index of effort. This relationship was demonstrated by Miss I. Ryhming (Stockholm) in a cycling and a step test modified from the well-known Harvard pack test. The new test gave similar results to the bicycling test and was easier to use in the factory. In an outstanding paper Prof. E. A. Muller (Dortmund) discussed the factors governing the pulse-rate/metabolic relationship, in particular the type and efficiency of the work, the cross-section of the muscles used and the extent of the static effort demanded by the work. For many patterns of work there existed a level of activity which could be sustained for hours. The energy expenditure at this optimal condition varied with the factors mentioned; but the pulse-rate difference between work and rest did not exceed about 35 beats/min.

How these findings can be applied to the analysis of the complete daily shift of industrial work was elucidated by Prof. G. Lehmann (Dortmund) and Prof. E. H. Christensen (Stockholm). Prof. Lehmann has used physiological measurements to obtain a more rational spacing of rest pauses in heavy industry and to eliminate the extra stresses imposed by unsuitable posture, static effort and adverse environmental temperatures. As a yardstick one can take an energy expenditure of 4 kcal./min. as the normal average output of a heavy worker. With a higher output per minute, rest pauses will usually be required to reduce the average output to 4 kcal./min. It is necessary to take full account not only of permitted rest periods but also of the arbitrary and enforced pauses which appear in all types of work and to rearrange these as recognized pauses so as to prevent the onset of fatigue. The pulse-rate determinations can be used extremely effectively in doing this, and the portable pulsometer and respirometer has made such investigations possible at the work place. Prof. Christensen's approach was complementary to that of the Dortmund workers, and he reported on ninety-odd different jobs studied in a steel factory. The heart-rate expected from the oxygen usage in these different tasks was compared with that actually observed, and, where this was excessively high, the cause was sought in the arrangement of the work, the methods used and the design of machinery, or often in the high temperatures prevailing. Changes could then be made and the degree of improvement evaluated. The performance of work, representing probably the limit of sustained human output, was the subject of a paper by Dr. M. J. Karvonin (Helsinki). He described the activities of lumberjacks taking part in the four-day national forest competition of Finland, a task which required an average daily consumption of 5,460 kcal., of which 40 per cent was derived from fat and 12 per cent from protein. The ability to work at this rate depended partly on the possession by lumberjacks of a physique quite different from that of the average Finn, but also on the incentive of the competition.

Apart from the more classical methods of determining the physiological cost of work, Dr. A. Lundervold (Oslo) indicated the value of electromyography. He described the results of his studies on typewriting in which he determined the muscles participating and the sequence of their activity. He also showed how the degree of their activity was increased by various forms of stress such as increased rate of work, fatigue and poor environmental conditions. The possible relationship between the increased static activity imposed by these stresses and myalgia was indicated. Dr. H. Seyffarth (Stockholm) emphasized the importance of ordinary clinical examination in studies such as these; examinations which can afford considerable insight into the conditions of the muscles. Dr. Gerda Seidelin (Copenhagen) also represented the clinical approach and stressed the limitation of activity that can be caused by poor body mechanics inducing pain. The pain may be relieved by the conventional physiotherapeutic methods; but permanent results are only achieved by correcting the posture, and this can be done only by studying the patient at the work which has produced the condition.

Of the contributions of the applied psychologists, the main emphasis was on the possible application of information theory to the measurement of man's overall performance in complex tasks. The place of the theory in the quantitative prediction of man's responses to known stimuli and *vice versa* was discussed by Dr. W. E. Hick (Cambridge). He stressed, however, that the position of the theory in this sphere is not clear and that, if established, will not replace more specific methods of investigation. Dr. W. D. Garvey (Washington, D.C.) described experiments in which he obtained a measure of the time necessary for a subject to code information by arranging that the display and response were constant. The results support earlier conclusions that the appropriate coding of information which the subject receives is an important factor in determining how much of it will be usefully dealt with. A different approach to the study of the application of information theory was reported by Mr. E. R. Crossman (Cambridge), who, by the use of a simple card-sorting task, showed that the overall time taken is mainly a function of the amount of choice made.

Illustrating the more specific criteria used in the study of man's performance were the papers of Dr. A. Leonard (Cambridge) and Dr. Shirley Spragg (Rochester, New York), both of which were concerned with display-control tasks. Dr. Leonard reported on experiments to determine the value of advanced information in such tasks, and Dr. Spragg on the effects of different relationships between the movement of the control and that of the display on tracking performance.

Work study was the subject for discussion at the concluding session. The importance of the practice was stressed because of the part it can play in increasing productivity and in coping with the ageing population; but it was pointed out by Mr. C. R. Wynne-Roberts (London) that, although it is an essential technique, it is only one of those available in industry for increasing individual efficiency. The present stage in the development of work study was outlined by Dr. D. Seymour (Birmingham), who considered that the advances being made are due to the application of pre-existing information rather than to an increase in fundamental data. The latter, though, is essential for the proper development of work study, and some improvement can be achieved by the dovetailing of the work of the psycho-physiologist and the engineer. A rather similar suggestion was put forward by Mr. R. Conrad (Cambridge), who stressed the need for bridging the gap between laboratory investigations and *ad hoc* studies in the factory. In his opinion, this can be done only by a willingness on the part of the psychologist to take the experimental methods at his disposal on to the shop floor and for the work-study engineer to present appropriate problems for laboratory investigation. Finally, Mr. L. G. Humble (London) gave a picture of the practical problems experienced in applying the results of work study, due to the resistance that is encountered both from the management and from the worker.

---

# INDUSTRY AND THE UNIVERSITIES IN BRITAIN

## CONFERENCE IN NOTTINGHAM

THE report of the conference on industry and the universities, organized by the Federation of British Industries North Midland Regional Council and the University of Nottingham, and held at Nottingham on September 24, 1952, has now been published*. It was the sixth regional conference of its kind to be held since the national conference on this subject held in November 1949, and the report includes the text of the following addresses: by Lord Hives on what industry requires from the universities; by Prof. J. A. Pope on whether universities can contribute to the needs of industry; by Sir Edward Herbert on what is the best training for the university student who wants to find a career in industry; and by Dr. F. A. Wells on the study of industrial organization and management as an academic discipline, and the contribution which industry itself can make in this field.

Lord Hives, who began by describing the methods used by Rolls Royce, Ltd., in dealing with an annual intake of about thirty university graduates, emphasized that his firm does not expect the universities to supply ready-made technicians, designers, metallurgists or chemists. It expects the universities to turn out men who are capable of thinking and who have received the basic training in the fundamental sciences essential to their future work; whose brains have been trained to tackle problems; and who, of their own initiative, can follow a problem through, step by step and logically, taking advantage of previous experience on allied work. Furthermore, said Lord Hives, his firm liked good citizens—men who can express themselves well and hold their own in the conference, and can report clearly and concisely on their work. Lord Hives does not believe that the universities can deal with specialized technological education satisfactorily; he is of the opinion that they are too remote from the rapidly changing requirements of industry, and they cannot afford the extensive and complicated equipment used in modern industrial engineering investigations.

For these reasons he said that he is doubtful as to the value of the proposal to establish an institute of technology and inclines to prefer graduates who come direct from their three years at a university to those who come from the Massachusetts Institute of Technology or one of the Continental technological institutes. The engineering industry, is, however, disturbed at the inadequate numbers of men coming from the universities, and Lord Hives suggested that the balance between arts students and those studying science and engineering is out of keeping with the

* Report of the Conference on Industry and the Universities, organised by the F.B.I. North Midland Regional Council and the University of Nottingham and held at the University, 24 September 1952. Pp. vii+39. (London: Federation of British Industries, 1953.) 4s. 6d.

demand. He stressed the importance of the appointments officers of the universities and suggested that they deserve better support. As regards quality, more first-class graduates are required and, particularly in the average man, an improvement in quality is desirable.

Sir Edward Herbert's address in some respects overlapped that of Lord Hives. He too agreed that industry recognizes that the first function of a university must always be that single-minded pursuit of learning and continual advance of knowledge which are essential to the existence and growth of a civilized society. The value of a university graduate in industry, or in any other walk of life, lies in the trained and flexible mind which the three or four years of mental discipline may be expected to produce. It does not lie in the possession of any particular body of knowledge, and Sir Edward suggested, in considering what qualities industry looks for in its recruits from the universities, that we should look not at the graduate starting his first job, but at the man he hopes to become at thirty-five or forty on the threshold of major responsibilities. His future would then turn, not on his specialized knowledge but on his capacity to assume responsibility.

Accordingly, Sir Edward thought, industry would seek for such future leaders a combination of three main categories of ability. First, the ability to equip oneself thoroughly with expert knowledge of the particular aspect of the business in which one is engaged; this provides the basis of genuine authority. Second is the ability to relate this specialist function to the conduct of the business as a whole, including not merely the problems of the industry but also of the community which that industry serves. The third is the ability to sustain the moral burden of responsibility. Sir Edward made no suggestion as to what formal part the university can hope to take in preparing a man for this last responsibility; but a university should, he thought, be able to foster a lasting regard for other human beings, and it should strive to instil the conception of duty and service. All who hold authority in a community should be constantly aware of the human implications of the decisions they have to make from day to day, but Sir Edward believed that professional training in business administration and management should come some time after the degree course, and not form part of it. Finally, he stressed the immense value of a friendly understanding between the universities and industry and the need for industry to become much more imaginatively alive to its own opportunities and achievements.

The importance of co-operation between the universities and industry was also stressed by Prof. Pope, who pointed out that, with the adequate financial assistance now available, practically all able boys and girls from the grammar and secondary schools in Britain are proceeding to a university; as a consequence, the direct entry into industry from schools has suffered considerably, and this is a problem which has been considered more particularly at a subsequent conference of the Federation of British Industries held last October. Apart from the professional qualifications, Prof. Pope maintained that a university education should discipline a person to be intellectually honest and to be capable of a balanced view of issues as they arrive.

While Dr. Wells also stressed the need for more and closer personal relations between industry and the universities, particularly on the social science side, his address was largely a plea for specific assistance from industry in providing material for economic studies. First, he said, more opportunities are needed for studying the organization of firms and for investigating their problems at first hand. Secondly, there is the desirability of having access to business records, particularly old historical records; and thirdly, the assistance of industry in developing the method of teaching based on case study. Fourthly, it is desirable to know more about the associations of the business world, such as the Federation of British Industries, the British Employers' Confederation and some of the more important sectional organizations. Far more, he said, is known of the trades union movement than of its counterpart on the employers' side.

---

# SOUTH AFRICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

## FIFTIETH ANNIVERSARY

WHEN the South African Association for the Advancement of Science met last year, during July 7–12, in the buildings of the University of Cape Town, it was to celebrate the golden jubilee of its foundation, for, though the date did not exactly coincide with fifty years, the occasion was fitting in that it was in Cape Town on September 12, 1901, when the constitution of the Association was drawn up, and on April 27, 1903, also in Cape Town, when the first annual meeting was held. The meeting last year, which was under the presidency of Dr. B. F. J. Schonland, of the Bernard Price Institute of Geophysical Research, Johannesburg, was marked by the invitation of the following distinguished guests from overseas: Sir Lawrence Bragg (Cambridge) and Sir Edward Salisbury (Kew Gardens); Prof. L. E. J. Brouwer (Amsterdam) and Prof. J. H. Oort (Leyden); Canon G. Lemaître (Louvain) and Prof. G. Magnel (Ghent); Dr. H. Vallois (Paris); and Prof. A. da Silva Rego (Lisbon). The official representatives of other bodies were as follows: for the sister Associations in Australia and New Zealand and in the United States, Sir Kerr Grant, the Australian physicist, and Dr. J. D. J. Hofmeyr, of Pretoria, respectively; for the Royal Society of South Africa, the oldest scientific society in the country (which, incidentally, was celebrating its seventy-fifth anniversary), Prof. R. W. James, of the University of Cape Town; and for the Suid-Afrikaanse Akademie vir Wetenskap, Dr. T. E. W. Schumann, director of the Weather Bureau of the Union of South Africa.

The activities of the meeting are recorded in the October–November issue of the Association's journal, the *South African Journal of Science*, and in this issue are published a brief description of the meeting, Dr. Schonland's presidential address and the texts of eleven papers, included in which are those of overseas visitors—namely, Dr. Vallois, Canon Lemaître, Prof. Oort, Prof. Rego, Sir Lawrence Bragg, Sir Edward Salisbury and Prof. Brouwer.

Dr. Schonland began his address by outlining the inception of the Association under the presidency of Sir David Gill, then H.M. Astronomer at the Cape, and showed how the early enthusiasm of the first meeting, at which 703 full members and 36 associates attended, led to a membership of 1,322 in 1906, which has never been since surpassed. Dr. Schonland expressed disappointment that the membership in recent years has been but a little more than a thousand, for South Africa has expanded enormously since 1906 and with this expansion the need for, and potential value of, such a body as the Association. The general aims of the Association have not changed at all with the passing of years: "We exist," he said, "primarily to create and foster a scientific fraternity in South Africa, not to publish original work. We exist to provide a common meeting-ground for South African scientists and a forum for general discussion of the problems of this country from the scientific angle." He defended the use of Afrikaans by those who preferred it, for "we were intended by our founders to be parochial, and we should pride ourselves on being parochial. I would suggest that if we try to be anything else we will have mistaken our real aim".

Having thus firmly and, most people would agree, wisely placed the Association in its proper perspective, Dr. Schonland went on to make some concrete suggestions. The *South African Journal of Science* should have a series of semi-popular articles reviewing and surveying the new ideas of science and so bridge the gap between those who teach and do advanced research work and those who pay for it. This, he thought, is the proper function of the *Journal*, and it is but one aspect of the Association's duty, as representative of all sections of scientific opinion in South Africa, "to take a stronger, a more continuing and a more active interest in all scientific developments, national and university, in South Africa and to study carefully what is being done in other countries".

Besides his plea that the Association needs to form a standing committee to watch over scientific education in schools, Dr. Schonland suggested that the Association might consider taking a part in the formation of a body on the lines of the British Parliamentary and Scientific Committee and also help in the creation of better facilities for advanced research in South Africa. On this last-named point, he cited the instances of the National University in Canberra and the Institute for Advanced Studies in Dublin, but he made the interesting suggestion that a more acceptable solution might be the creation of a number of specialized institutes for advanced study, attached to and forming part of those universities which for one reason or another are best suited for them.

# BASIS OF TECHNICAL EDUCATION

GENERAL education to-day should be planned so as to enable the ordinary citizen to adapt himself to the needs of technological society and to understand what is happening and what is required of him. This was the theme of an international conference convened by the United Nations Educational, Cultural and Scientific Organization at Unesco House in June 1950*.

Broadly, the Conference found that organized social foresight is essential to enable the educational system of a country to prepare children for the type of life and work they are likely to encounter, and that a substantial development of technical education is required at all levels: at present it is wholly inadequate for future needs, while the practical content of general education is also inadequate for the needs of future citizens of a technological society. The cultural content of technical education is also generally inadequate; technical education requires special consideration, and training for adaptability is an outstanding requirement in an age of ultra-rapid technological change. The education of women and girls also demands particular attention in view of their dual role as workers and home-makers, and improved administrative arrangements are essential if education is to fulfil its true function in such a society.

The report does not suggest that all these propositions apply equally to every country, though the Conference considered that, so far as its knowledge extended, they are generally valid for the world as a whole. The stress is laid on the need for adapting technology to man, not man to technology. The questions formulated in this report—and which merit attention in current discussions on the expansion of both technical and technological education in Great Britain—are raised in the belief that mastery of the machine by man is not an end in itself: it is a means to the development of man and of the whole society.

The distinction between technician and technologist is not always kept clear in this report, particularly in the chapter on the content of technical education. Nevertheless, the report directs attention to some fundamental issues which no sound policy for either type of education can disregard. In both fields it must be recognized that we are concerned not simply with the efficiency of production, but also with the fundamental attitude which the men and women of to-morrow will adopt in facing the problems of a technological society. Both, too, in seeking to foster flexibility, must recognize that flexibility is determined not only by education and training but also by social, economic and technical conditions; and the administrative measures required to ensure that education becomes more adapted to the needs of a changing technological society are themselves likely to be most effective when they are informal and varied rather than concentrated and uniform. The administrator, no less than the teacher and student, has need of frequent opportunities of contact with the industrial world, and requires experience of the difficulties and problems created by technological development in society; just as the teacher and student should keep abreast of developments in research and of practical applications in industry.

# GENETICAL IMPLICATIONS OF THE STRUCTURE OF DEOXYRIBONUCLEIC ACID

By J. D. WATSON and F. H. C. CRICK

Medical Research Council Unit for the Study of the Molecular Structure of Biological Systems, Cavendish Laboratory, Cambridge

THE importance of deoxyribonucleic acid (DNA) within living cells is undisputed. It is found in all dividing cells, largely if not entirely in the nucleus, where it is an essential constituent of the chromosomes. Many lines of evidence indicate that it is the carrier of a part of (if not all) the genetic specificity of the chromosomes and thus of the gene itself.

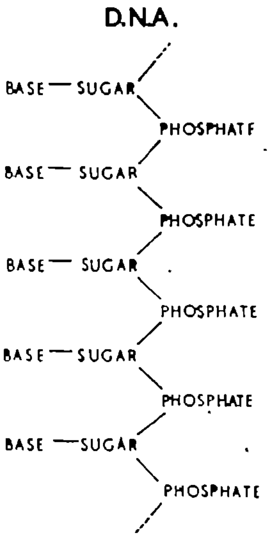

Fig. 1. Chemical formula of a single chain of deoxyribonucleic acid

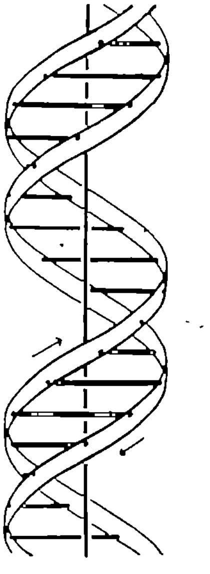

Fig. 2. This figure is purely diagrammatic. The two ribbons symbolize the two phosphate-sugar chains, and the horizontal rods the pairs of bases holding the chains together. The vertical line marks the fibre axis

Until now, however, no evidence has been presented to show how it might carry out the essential operation required of a genetic material, that of exact self-duplication.

We have recently proposed a structure[1] for the salt of deoxyribonucleic acid which, if correct, immediately suggests a mechanism for its self-duplication. X-ray evidence obtained by the workers at King's College, London[2], and presented at the same time, gives qualitative support to our structure and is incompatible with all previously proposed structures[3]. Though the structure will not be completely proved until a more extensive comparison has been made with the X-ray data, we now feel sufficient confidence in its general correctness to discuss its genetical implications. In doing so we are assuming that fibres of the salt of deoxyribonucleic acid are not artefacts arising in the method of preparation, since it has been shown by Wilkins and his co-workers that similar X-ray patterns are obtained from both the isolated fibres and certain intact biological materials such as sperm head and bacteriophage particles[2,4].

The chemical formula of deoxyribonucleic acid is now well established. The molecule is a very long chain, the backbone of which consists of a regular alternation of sugar and phosphate groups, as shown in Fig. 1. To each sugar is attached a nitrogenous base, which can be of four different types. (We have considered 5-methyl cytosine to be equivalent to cytosine, since either can fit equally well into our structure.) Two of the possible bases—adenine and guanine—are purines, and the other two—thymine and cytosine—are pyrimidines. So far as is known, the sequence of bases along the chain is irregular. The monomer unit, consisting of phosphate, sugar and base, is known as a nucleotide.

The first feature of our structure which is of biological interest is that it consists not of one chain, but of two. These two chains are both coiled around a common fibre axis, as is shown diagrammatically in Fig. 2. It has often been assumed that since there was only one chain in the chemical formula there would only be one in the structural unit. However, the density, taken with the X-ray evidence[2], suggests very strongly that there are two.

The other biologically important feature is the manner in which the two chains are held together. This is done by hydrogen bonds between the bases, as shown schematically in Fig. 3. The bases are joined together in pairs, a single base from one chain being hydrogen-bonded to a single base from the other. The important point is that only certain pairs of bases will fit into the structure. One member of a pair must be a purine and the other a pyrimidine in order to bridge between the two chains. If a pair consisted of two purines, for example, there would not be room for it.

We believe that the bases will be present almost entirely in their most probable tautomeric forms. If this is true, the conditions for forming hydrogen bonds are more restrictive, and the only pairs of bases possible are :

adenine with thymine ;
guanine with cytosine.

The way in which these are joined together is shown in Figs. 4 and 5. A given pair can be either way round. Adenine, for example, can occur on either chain ; but when it does, its partner on the other chain must always be thymine.

This pairing is strongly supported by the recent analytical results[5], which show that for all sources of deoxyribonucleic acid examined the amount of adenine is close to the amount of thymine, and the amount of guanine close to the amount of cytosine, although the cross-ratio (the ratio of adenine to guanine) can vary from one source to another. Indeed, if the sequence of bases on one chain is irregular, it is difficult to explain these analytical results except by the sort of pairing we have suggested.

The phosphate-sugar backbone of our model is completely regular, but any sequence of the pairs of bases can fit into the structure. It follows that in a long molecule many different permutations are possible, and it therefore seems likely that the precise sequence of the bases is the code which carries the genetical information. If the actual order of the

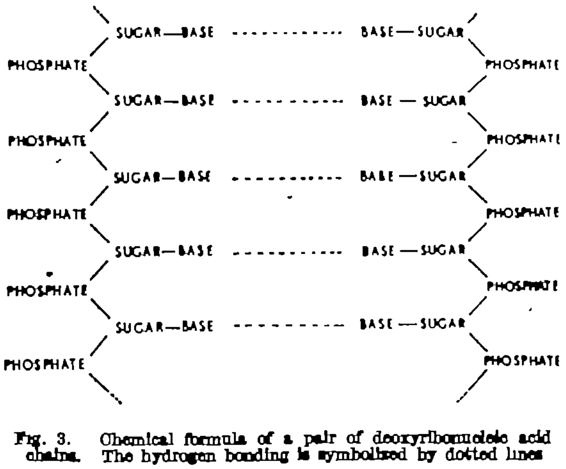

Fig. 3. Chemical formula of a pair of deoxyribonucleic acid chains. The hydrogen bonding is symbolized by dotted lines

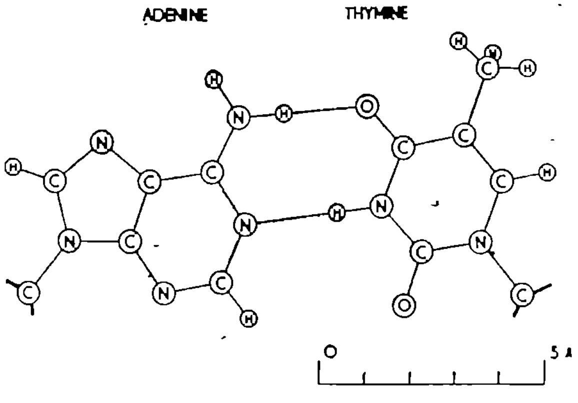

Fig. 4. Pairing of adenine and thymine. Hydrogen bonds are shown dotted. One carbon atom of each sugar is shown

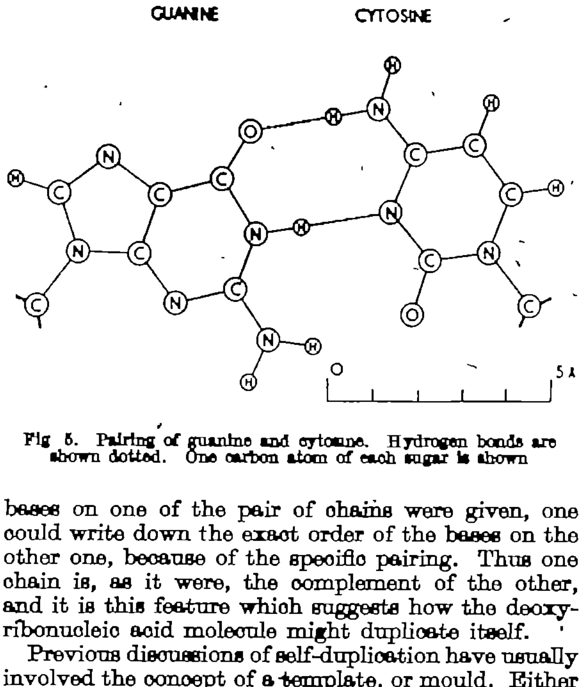

Fig 5. Pairing of guanine and cytosine. Hydrogen bonds are shown dotted. One carbon atom of each sugar is shown

bases on one of the pair of chains were given, one could write down the exact order of the bases on the other one, because of the specific pairing. Thus one chain is, as it were, the complement of the other, and it is this feature which suggests how the deoxyribonucleic acid molecule might duplicate itself.

Previous discussions of self-duplication have usually involved the concept of a template, or mould. Either the template was supposed to copy itself directly or it was to produce a 'negative', which in its turn was to act as a template and produce the original 'positive' once again. In no case has it been explained in detail how it would do this in terms of atoms and molecules.

Now our model for deoxyribonucleic acid is, in effect, a *pair* of templates, each of which is complementary to the other. We imagine that prior to duplication the hydrogen bonds are broken, and the two chains unwind and separate. Each chain then acts as a template for the formation on to itself of a new companion chain, so that eventually we shall have *two* pairs of chains, where we only had one before. Moreover, the sequence of the pairs of bases will have been duplicated exactly.

A study of our model suggests that this duplication could be done most simply if the single chain (or the relevant portion of it) takes up the helical configuration. We imagine that at this stage in the life of the cell, free nucleotides, strictly polynucleotide precursors, are available in quantity. From time to time the base of a free nucleotide will join up by hydrogen bonds to one of the bases on the chain already formed. We now postulate that the polymerization of these monomers to form a new chain is only possible if the resulting chain can form the proposed structure. This is plausible, because steric reasons would not allow nucleotides 'crystallized' on to the first chain to approach one another in such a way that they could be joined together into a new chain, unless they were those nucleotides which were necessary to form our structure. Whether a special enzyme is required to carry out the polymerization, or whether the single helical chain already formed acts effectively as an enzyme, remains to be seen.

Since the two chains in our model are intertwined, it is essential for them to untwist if they are to separate. As they make one complete turn around each other in 34 A., there will be about 150 turns per million molecular weight, so that whatever the precise structure of the chromosome a considerable amount of uncoiling would be necessary. It is well known from microscopic observation that much coiling and uncoiling occurs during mitosis, and though this is on a much larger scale it probably reflects similar processes on a molecular level. Although it is difficult at the moment to see how these processes occur without everything getting tangled, we do not feel that this objection will be insuperable.

Our structure, as described[1], is an open one. There is room between the pair of polynucleotide chains (see Fig. 2) for a polypeptide chain to wind around the same helical axis. It may be significant that the distance between adjacent phosphorus atoms, 7·1 A., is close to the repeat of a fully extended polypeptide chain. We think it probable that in the sperm head, and in artificial nucleoproteins, the polypeptide chain occupies this position. The relative weakness of the second layer-line in the published X-ray pictures[3,4] is crudely compatible with such an idea. The function of the protein might well be to control the coiling and uncoiling, to assist in holding a single polynucleotide chain in a helical configuration, or some other non-specific function.

Our model suggests possible explanations for a number of other phenomena. For example, spontaneous mutation may be due to a base occasionally occurring in one of its less likely tautomeric forms. Again, the pairing between homologous chromosomes at meiosis may depend on pairing between specific bases. We shall discuss these ideas in detail elsewhere.

For the moment, the general scheme we have proposed for the reproduction of deoxyribonucleic acid must be regarded as speculative. Even if it is correct, it is clear from what we have said that much remains to be discovered before the picture of genetic duplication can be described in detail. What are the polynucleotide precursors ? What makes the pair of chains unwind and separate ? What is the precise role of the protein ? Is the chromosome one long pair of deoxyribonucleic acid chains, or does it consist of patches of the acid joined together by protein ?

Despite these uncertainties we feel that our proposed structure for deoxyribonucleic acid may help to solve one of the fundamental biological problems—the molecular basis of the template needed for genetic replication. The hypothesis we are suggesting is that the template is the pattern of bases formed by one chain of the deoxyribonucleic acid and that the gene contains a complementary pair of such templates.

One of us (J.D.W.) has been aided by a fellowship from the National Foundation for Infantile Paralysis (U.S.A.).

# GEOPHYSICAL AND METEOROLOGICAL CHANGES IN THE PERIOD JANUARY–APRIL 1949

In a recent article[1] Lewis and McIntosh have considered the geophysical data for the period January–April 1949, which we presented in an earlier communication[2]. On the basis of certain probability criteria they appear to show that the apparent regular variations in ionospheric and meteorological phenomena which occurred in that period were not significant. We have studied their article and made a separate statistical analysis of the *unsmoothed* data, and conclude that in all respects our original suggestions seem to be valid.

In our original article we presented graphs showing five-day moving averages in four parameters: (*a*) ground pressure, $p$; (*b*) $E$-layer critical frequency, $fE$; (*c*) $F$-layer critical frequency, $fF2$; and (*d*) $K$-index of geomagnetic activity. The connexion between ionospheric and geomagnetic phenomena is well known. Thus, Appleton and Ingram[3] in 1935 established the correlation between geomagnetic activity and depressions in $fF2$. It is worthy of note that in the period under discussion the inverse correlation between $K$ and $\Delta fF2$ is, as Lewis and McIntosh point out, considerably less striking than that between $p$ and $\Delta fE$ (cf. Figs. 1 and 2 in our original article). It would seem, then, that if statistical analysis can be successfully applied to show that there is no significance between the variations in $p$ and $\Delta fE$, it is, *a fortiori*, evident that a similar analysis might, in the present instance, be used for discrediting the established relationship between $K$ and $\Delta fF2$. Conversely, of course, the fact that a phenomenon appears to be statistically significant over a short period must likewise be treated with reserve. The need for the utmost care in the application and interpretation of statistical analyses to such a limited time series is thus clear.

From inspection of our graphs it seemed to us that, so far as $p$ and $\Delta fE$ were concerned, the period was unusual in three respects: (i) there appeared to be four oscillations in ground pressure showing a progressive diminution of amplitude, with an average period of about 27 days; (ii) in like manner there appeared to be four marked oscillations of period about 27 days in $\Delta fE$; (iii) oscillations (i) and (ii) appeared to be almost exactly out of phase. In addition, we noted that the period was characterized by an unusual 27-day recurrence of great sudden commencement (S.C.) magnetic storms.

In our original communication we merely directed attention to these matters, and suggested that there might be some connexion between them. We did not then suggest, nor do we now suggest, that from a period of length only four months any conclusions can be drawn regarding the general behaviour over a long period of any of the geophysical parameters considered. The severely limited number of observations available, together with the fact that there is considerable uncertainty about the correct statistical approach to time series analysis, seemed to us sufficient reason for not entering into an extended statistical analysis.

However, the contrary conclusions reached by Lewis and McIntosh (see below) have prompted us to re-examine the data. Briefly, their conclusions are: (i) the 27-day oscillation in ground pressure is of no significance, since the amplitude is no more than would be expected from mere chance considerations; (ii) the 27-day oscillation in $\Delta fE$ is probably significant; (iii) oscillations (i) and (ii) are exactly in anti-phase; (iv) there is no significant correlation coefficient between the $p$ and $\Delta fE$ data; (v) our conclusions arise from smoothing of the data.

We shall now outline our own analysis. In various communications[4–6], Kendall has made it abundantly clear that most of the methods generally used for studying periodicities in time series (for example, periodograms, Fourier analysis, etc.) may yield very misleading results when applied to the kind of time series with which we are here concerned. He has also questioned the reliability of the usual significance tests for periodicities when applied in time series analysis. Kendall has shown that the most reliable approach is that of serial correlation coefficients as exhibited in the correlogram. He points out that although the correlogram may be insensitive, it does give a lower limit to the oscillatory effects, and that if it oscillates there is almost certainly some systematic oscillation in the primary series explored. Figs. 1 and 2 show the correlograms for $\Delta p$ and $\Delta fE$ respectively for the period under consideration. In both of these the original *unsmoothed* data have been used.

It is important to note that there is a marked trend in the pressure data, and to eliminate this we have dealt with values of pressure departures, $\Delta p$ (as with the $fE$ data), rather than with the absolute magnitudes $p$. The oscillations in both correlograms are clear, with a maximum at 26–27 days in each case. These correlograms provide strong support for our original deductions (based, as they were, on simple inspection of graphs), and make it essential for us to repeat Lewis and McIntosh's calculations.

At the outset we must again stress that the pressure data exhibit a marked downward trend (approximately linear), and it is imperative initially to eliminate this before proceeding with any numerical analysis. It appears that Lewis and McIntosh have overlooked this point, and as a result have arrived at quite contrary conclusions. This will be clear from an examination of Table 1, in which we present the results of calculations made by us using (i) pressure, $p$, (ii) pressure departures, $\Delta p$, and (iii) $fE$ departures, $\Delta fE$. The nomenclature employed ($c$, $\varphi$, $\sigma$, etc.) is that used by Lewis and McIntosh.

Without going into details, it can be stated that there is little significant difference between the present results *using pressure*, $p$, and those given by Lewis and McIntosh. The slight differences in the values of amplitude $c$ and first serial correlation coefficient $r_1$ are of no significance and can be ascribed to different ways of deducing the amplitude and phase of a 27-day oscillation from data covering four such oscillations, or to rounding-off processes used in the calculations. However, the significance criteria $P_S$ and $P_F$ are very sensitive to small changes in the 'modified amplitude ratio' $a'$, and the net values obtained by us are somewhat lower than those given by Lewis and McIntosh. In this calculation we have not eliminated the trend in the pressure values; the amplitudes, etc., really refer to oscillation about the arithmetic mean of all the data. Clearly, when there is a marked trend in the data, this is an incorrect procedure.

Table 1

| | $c$ | $\varphi$ | $\sigma$ | $a$ | $r_1$ | $a'$ | $P_S$ | $P_F$ |
|---|---|---|---|---|---|---|---|---|
| (i) $p$ | 5·8 mb | 244° | 8·8 mb. | 0·47 | 0·65 | 0·25 | 0·033 | 0·891 |
| (ii) $\Delta p$ | 6·6 mb. | 251° | 8·1 mb. | 0·59 | 0·57 | 0·34 | 0·003 | 0·079 |
| (iii) $\Delta fE$ | 0·06 Mc/s. | 63° | 0·09 Mc./s. | 0·49 | 0·29 | 0·37 | 0·0006 | 0·021 |

Table 2

| | $c$ | $\varphi$ | $\sigma$ | $a$ | $r_1$ | $a'$ | $P_S$ | $P_F$ |
|---|---|---|---|---|---|---|---|---|
| $\Delta p$ | 7·4 mb. | 271° | 8·1 mb. | 0·65 | 0·57 | 0·37 | 0·0008 | 0·029 |
| $\Delta fE$ | 0·07 Mc/s. | 85° | 0·09 Mc./s. | 0·55 | 0·29 | 0·41 | 0·00015 | 0·004 |

Thus, when we eliminate the effect of the trend in the pressure data, it is seen that the modified amplitude ratio $a'$ is now some 35–40 per cent larger, with the result that $P_S$ and $P_F$ are reduced by factors of more than ten. The present values of $P_S$ and $P_F$, namely 0·003 and 0·079, may be compared with the 0·057 and 0·989 respectively given by Lewis and McIntosh. It is clear that, far from being a chance phenomenon, the amplitude of the 27-day pressure oscillation even on the Fisher probability criterion is nearly within the 5 per cent significance level. So far as the $\Delta fE$ calculation is concerned, our modified amplitude ratio $a'$ is slightly larger than that deduced by Lewis and McIntosh, but this alone is sufficient to reduce both $P_S$ and $P_F$ by a factor of more than 2, such that $P_F$ is now well within the 5 per cent significance level.

A careful examination of Figs. 1 and 2 shows that in each case the peak of the correlograms occurs nearer 26 than 27 days. Accordingly, we have repeated the above statistical analysis for $\Delta p$ and $\Delta fE$ for the case of a 26-day oscillation. The results are summarized in Table 2.

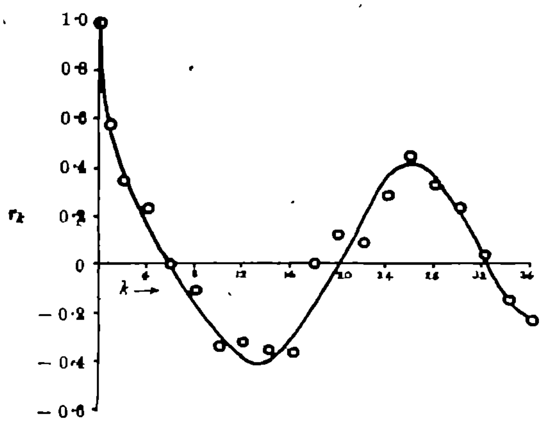

Fig. 1. Correlogram for pressure departures

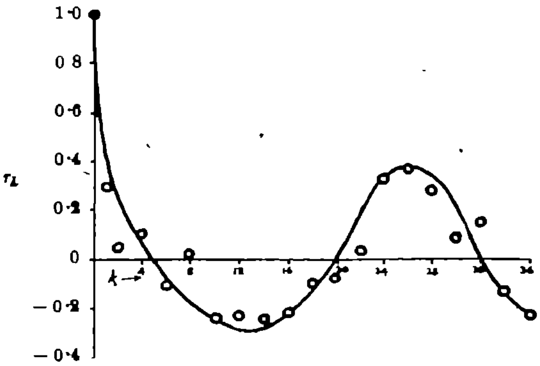

Fig. 2. Correlogram for $fE$ departures

In this case, it will be seen that the amplitudes for both series are larger than in the 27-day case, and the values of the probability criteria are in all cases extremely small, indicating that the oscillations are indeed quite significant.

The three lines of approach which we have now considered—direct inspection of the original graphs, the correlograms of Figs. 1 and 2, and the statistical analysis outlined above—are in agreement, and all point to the reality of these 26–27-day oscillations *in this particular period*. We should add that we have examined data over many years of the kind considered above and have not found any similar period having such striking variations as characterized this particular 4-month period. It would seem that the large 27-day variations apparent here, and supported by statistical analysis, are probably of rare occurrence.

One further point might be considered. Apart from the fact that each series $\Delta p$ and $\Delta fE$ separately exhibits a 26–27-day oscillation, it is also worth noting that the two oscillations are almost exactly in antiphase. The correlation coefficient between $\Delta p$ and $\Delta fE$ for 105 available pairs is $-$ 0·37. (In their analysis of $p$ and $\Delta fE$, Lewis and McIntosh used ninety pairs of correlates. The additional fifteen $fE$ values used by us were obtained by interpolating missing noon values from measurements made at 1100 and 1300 hr.). In testing the significance of this correlation coefficient, we must make due allowance for the effect of coherence in the daily observations. This is usually done by reducing the number of observations by a factor $\varepsilon$ (called the equivalent number of repetitions). Bartels[7] has given a relationship between $\varepsilon$ and the successive serial correlation coefficients of a series (equation (2) of Lewis and McIntosh's paper). Using this, we obtain $\varepsilon \doteqdot 4$ for the $\Delta p$ series, and $\varepsilon \doteqdot 2$ for the $\Delta fE$ series. The number of independent pairs must thus be taken as lying between 26 and 52. Using the approximation due to Fisher (quoted by Lewis and McIntosh), we then find a probability of 0·06 that 26 pairs will have a correlation coefficient $\geqslant$ 0·37; for 52 pairs the probability is 0·008. These figures are to be compared with the probabilities 0·436 and 0·148 respectively given by them. The considerable differences between these figures arise here, as in the Fourier analysis considered above, from the fact that they omitted to eliminate the trend in the pressure data. Concerning the values of $\varepsilon$, it might be argued that such a difference in degree of conservation is evidence against direct physical connexion between the parameters. However, too much significance should not be placed on the actual values, since (a) we have here only a very limited sample of data, and (b) the accuracy of measurement of $fE$ is somewhat less than that of $p$, and this diminished degree of accuracy in itself tends to reduce the calculated value of $\epsilon$. The fact that the $\epsilon$'s are different and that the correlation coefficient between $\Delta p$ and $\Delta fE$ is not particularly large may perhaps be taken to indicate that there is little direct physical connexion between the variations in $p$ and $fE$, but that both might be affected by a common extraneous cause.

---

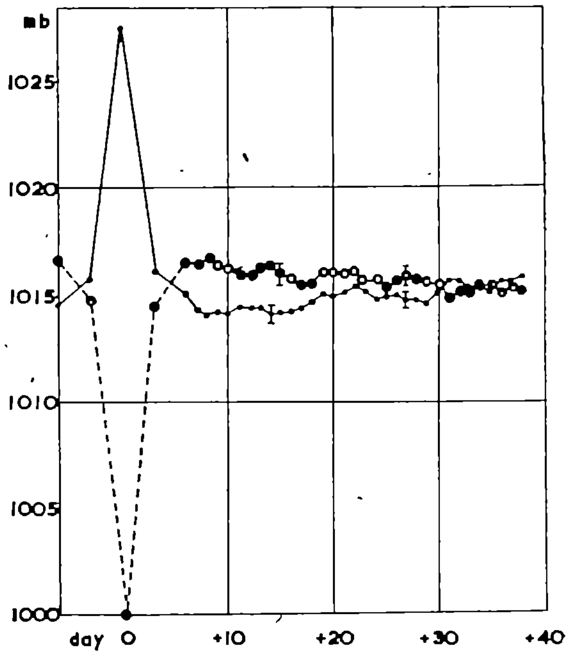
We should like to make the following comments on the communication by Beynon and Brown.

(1) The fact that the correlation between $K$ indices and $fF2$ is not necessarily significant over the period under discussion cannot "discredit the established relationship", because this correlation is known to persist as more and more data are taken; the lack of significance is due to the smallness of the sample. (In fact, the correlation coefficient between $fF2$ and corresponding daily sums of $K$ indices was $-0{\cdot}21$, that is, almost the same as that between $p$ and $\Delta fE$.)

(2) The use of correlograms adds nothing to the previous graphical representation of smoothed variations, since no numerical significance test is applied.

(3) The differences between our results and those obtained by Beynon and Brown result from their use of values of $\Delta p$ rather than $p$. We did not overlook the fact that there is an apparent downward trend in the pressure data, but we did not on that account use $\Delta p$ instead of $p$ for the following reasons. The monthly means of $fE$ closely depend on the sun's zenith angle, and the variation of $fE$ with factors other than the sun's zenith angle is clearly best considered by taking departures ($\Delta fE$) from the smooth curve joining the monthly means, as was done in both analyses. In contrast, pressure at Kew shows no annual variation ascribable to a simple physical cause: monthly means of $p$ at Kew are widely scattered for corresponding months from year to year, and the long-period means show a small and irregular annual variation. An apparent 'trend' in any individual period is consequently as much a part of the true variability of $p$ as are the 'departures' ($\Delta p$) from the 'trend', and should not be eliminated before applying numerical tests. (It may be remarked that in Beynon and Brown's original paper $p$, and not $\Delta p$, was plotted and discussed.)

(4) It is difficult to conceive the possible nature of a physical agency responsible for causing world-wide variations in $fE$ and simultaneous—but geographically very restricted—large variations in surface pressure. We would re-emphasize that this difficulty makes it very necessary for the $p$ and $\Delta fE$ variations to be shown to be much closer than may be explained by the method of choice of this particular period, namely, the sequence of four maxima in $p$ at 27-day intervals. We consider the facts as presented in our analysis to be entirely compatible with a chance general similarity of $p$ and $\Delta fE$ with therefore no common physical cause.



Mean variation of Kew surface pressure at midday around 600 selected days of pressure-peak (●—●—) and of pressure-trough (○--○--) during 1926–50

(5) Independent evidence of the existence of a direct effect of variations of solar radiation on those of surface pressure is given by the results of a study we have made of pressure-recurrence tendencies. Our method followed that used so successfully by Chree and Stagg[1] for demonstrating the effect of the solar rotation period on geomagnetic disturbance. Two days of clearly defined mid-day pressure maximum at Kew were selected for each month in the period 1926–50. Independence was secured by ensuring that no two maxima in the whole pressure series were nearer than 7 days. The statistical variation of pressure was then determined from 6 days before to 38 days after the 600 selected pressure-peak days. The variation of pressure was also determined around 600 pressure-trough days selected in a similar way. The results are shown in the accompanying graph, in which the standard errors of the means are indicated.

The curves indicate complete randomness in the occurrence of lengths of interval separating pressure peaks and also in those separating pressure troughs. Subdivision of the data according to season and sunspot epoch gave similar results. It may be noted in particular that in neither case is there evidence of any systematic pressure effect after an interval of about 27 days. The method of analysis is independent of changes of phase or intermittency. Beynon and Brown state that in many years they have found no recurrence of the large 27-day pressure variation: our result shows that an oscillation of about this length had no more than random occurrence during 1926–50.

## Functional Relations of the Adenohypophysis and Hypothalamus

THE means by which the pars distalis of the adenohypophysis ('the anterior lobe of the pituitary' or 'anterior lobe') adjusts its secretions to the requirements of the body continue to be the subject of much inquiry and speculation. Apart from the reciprocal interaction of the anterior lobe with such endocrine organs as are under its control (for example, the adrenal cortex and gonads), it is generally accepted that the gland is able to respond to changes which are mediated through the nervous system. For example, it is known that the reproductive organs of the ferret, which in Great Britain breeds only between March and August, can be activated during the winter months if the animal is exposed to additional light. This response is dependent on the presence of (*a*) the retina, (*b*) the pituitary, and (*c*) the gonads, and the presumption is that nerve impulses, first transmitted along the optic pathways, in some way stimulate the anterior pituitary to secrete gonadotrophic hormone. Unfortunately, attempts to track the actual pathways by which the impulses are relayed from the optic pathways to the gland have in large part failed[1]. Moreover, while it is definitely established that the whole neurohypophysis is innervated by hypothalamic nuclei, there is no agreement that nerve fibres reach the pars distalis of the adenohypophysis from this region of the brain[2]. Such sympathetic and parasympathetic fibres as enter it on the walls of the blood-vessels are usually assumed to be mainly vasomotor in function[3].

Attention has recently been focused on the hypophysial-portal system of vessels as the controlling link between the pituitary and the hypothalamus, and in elaborating this view Harris has suggested[3,4] that impulses from the hypothalamus, which is connected by fibre tracts to most parts of the brain, stimulate the secretion of some 'chemotransmitter' substances within the median eminence in the floor of the third ventricle, and that these then pass down the portal vessels into the sinusoids of the anterior pituitary to modulate the activity of the secretory cells of the pituitary. Harris, whose experiments have been performed on rabbits and rats, also suggests that the persistence of normal anterior pituitary function after section of the pituitary stalk is due to the reconstitution of the portal vessels; and he indicates that pituitary function is scarcely likely to be normal if the vessels do not regenerate.

Some general issues which need to be resolved if this attractive hypothesis is to be sustained have been discussed elsewhere[5]. The present and preliminary note describes certain experiments which show that ferrets can become oestrous as a result of artificial illumination in the winter even after the elimination of the hypophysial-portal system of vessels.

In these experiments the pituitary stalk was divided by means of an operative procedure described elsewhere[6]. In some animals the stalk was just sectioned; in others a small fragment of muscle was gently inserted between the pituitary and the base of the brain; in a third series, a small piece of waxed paper was used instead of muscle. With few exceptions, histological examination showed that the paper had been eliminated from the wound some time between the operation and autopsy.

Seven of twenty-three ferrets submitted to these procedures, and in which the stalk had been completely sectioned (with the consequent disappearance of the processus infundibularis), failed to come into heat when illuminated by means of electric light during the winter months. In all these animals the distal end of the proximal stump of the stalk had become either adherent to the superior surface of the anterior part of the pituitary, or closely connected to it by reaction tissue. In both cases there was a clear anastomosis between the vessels in the two structures. In most of these seven animals the pars distalis was smaller than normal, and the arrangement of its constituent cells also appeared abnormal.

The remaining sixteen animals came into heat. In six, histological examination of the base of the brain and the sella turcica showed that the stalk had been incompletely severed, and that the processus infundibularis had not involuted. In the remaining ten, the stalk had been completely divided, and the processus infundibularis had disappeared. In most of these the proximal stump had either become adherent to the pars distalis, or the two had become connected by means of reaction tissue. In a few of these it could safely be said that the vessels in the stalk, including portal vessels, had re-established a connexion with the sinusoids of the pars distalis. In others, the anastomosis was more doubtful, and it was possible that, in addition to communicating with the sinusoids, vessels of the stalk were also anastomosing directly with veins in the surrounding fibrous tissue, and thus with neighbouring dural sinuses.

In one critical case, however, the pars tuberalis had been so severely damaged that it was neither possible to recognize cells which could be designated as tuberalis cells, nor the primary loops of the portal vessels. In another ferret, paper, new bone and fibrous tissue intervened between the pituitary gland and the part of the brain anterior to the base of the stalk, there being no trace of any vascular connexion between the two. Both these animals reacted to light by becoming oestrous.

A detailed account of these experiments will be published elsewhere. They show that the gonads of the ferret will respond to additional light during the winter, when there appears to be no possibility of impulses emanating in the retina being transmitted via the hypothalamus to the pars distalis of the pituitary, either directly by a nervous pathway, or indirectly, through the pituitary-portal system of vessels. Our experiments do not give any indication of the way in which the response is mediated, and we are continuing our study of this essential problem.

## Therapeutic Action of Glutathione and Mercaptoethylamine against a Lethal Dose of X-Rays

IT has been shown that the shielding of the liver *in situ* protects 73 per cent of a group of rats against a dose of X-rays which is 100 per cent lethal after fifteen days for the control animals[1]. E. S. G. Barron[2] showed that glutathione had a protective action in mice when injected before the lethal irradiation. Bacq and his co-workers[3] have shown that β-mercaptoethylamine protects mice against a lethal dose of X-rays when this compound is injected into the animals immediately before the total body irradiation. We have been able to confirm these results in rats[4]. On the other hand, the β-mercaptoethylamine is completely inactive when given even immediately after the exposure to a lethal dose.

The purpose of this short communication is to show the therapeutic action of reduced glutathione and of β-mercaptoethylamine against a lethal irradiation when the rats have the liver area shielded during the exposure. Six groups of twenty-four rats each have been irradiated over the entire body with a dose of 1·130 r. measured with the Victoreen X-ray condenser r.-meter. The apparatus used is a 250-kV. Maximar X-ray machine of the General Electric Co. The distance anticathode – animal is 55 cm., the voltage 180 kV., 15 m.amp., with no secondary filter. The first group of rats was irradiated over the entire body. A second group received the same dose, the liver area being shielded with a lead foil of 5 mm. thickness protecting an area of 5 cm. × 3 cm. corresponding to the liver region. A third group was irradiated as the second group (liver region protected); but the animals were injected immediately after the irradiation, 6 hr. and 12 hr. later, with an intraperitoneal dose of 7 mgm. of β-mercaptoethylamine. The fourth group was irradiated over the whole body like the first group but injected with β-mercaptoethylamine as the animals of the third group. The fifth group was irradiated as the second group (liver region protected), but the animals were injected intraperitoneally with 12 mgm. of reduced glutathione immediately after the irradiation, 6 hr. and 12 hr. later. The sixth group was irradiated over the whole body like the animals of the first group, but were injected with reduced glutathione as were the animals of the fifth group. The number of survivors is shown in the accompanying table.

This type of experiment was carried out twice with the same general results, and shows that reduced glutathione and β-mercaptoethylamine have a therapeutic action when injected into rats exposed to a lethal body-dose of X-rays if the liver area is shielded during the exposure.

| Group | I | II | III | IV | V | VI |
|---|---|---|---|---|---|---|
| Dose | 1,130 r. alone | 1,130 r. + lead shield on liver | 1,130 r. + lead shield on liver + 3 × 7 mgm. mercaptoethylamine | 1,130 r. + 3 × 7 mgm. mercaptoethylamine | 1,130 r. + lead shield on liver + 3 × 12 mgm. glutathione | 1,130 r. + glutathione |
| No. of animals | 24 | 24 | 24 | 24 | 24 | 24 |
| Days after X-rays | | | | | | |
| 7 | 4 | 16 | 20 | 3 | 24 | 1 |
| 14 | 0 | 8 | 18 | 0 | 18 | 0 |
| 21 | 0 | 7 | 15 | 0 | 17 | 0 |
| 30 | 0 | 5 | 14 | 0 | 11 | 0 |

We have repeated the experiment with rats having an equivalent area of the costal region protected during the irradiation. In such conditions β-mercaptoethylamine has practically no therapeutic action.

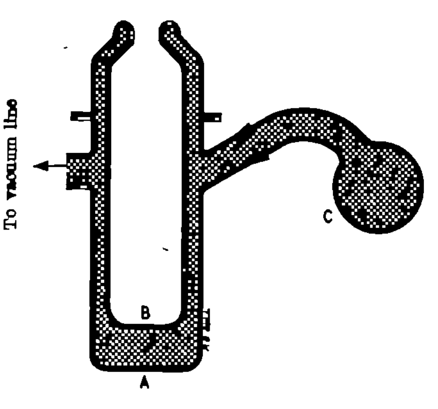
## A Simple Tissue Freeze-drying Apparatus using the Principle of Short-path Sublimation

WITH increasing recognition of the advantages of the freezing and drying of tissues for cytochemical studies, it is of interest to describe a cheap and efficient drying apparatus which has been in continuous use during the past two years.

The dryer works on the principle of short-path sublimation[1] and is constructed of 'Pyrex' glass. The quenched tissue is placed in the bottom of the drying chamber (*A*), which is immersed in an ethyl oxalate/solid carbon dioxide mixture giving a temperature of – 40° C. The top of the chamber is then placed in position and the system evacuated by a commercial diffusion pump and a rotary pump. The condensing finger is then filled with liquid air or nitrogen, which cools the condensing surface *B*, placed 3 cm. away from the tissues. The operating pressure is $10^{-4}$ to $10^{-5}$ mm. mercury, giving a mean free path for the water molecules of about 50 cm. This permits straight-path sublimation of the water molecules from the specimens to the condenser. At the end of the drying time, the drying chamber is slowly warmed by hot water to a temperature just above the melting point of the embedding wax used. The



previously degassed wax in $C$ is just melted and then poured on the tissue by rotating $C$ in its socket. After a short interval, the vacuum is released and the tissues blocked out.

In our original model the embedding wax was a lining to the bottom of the drying chamber during the drying cycle; but it acted as a thermal insulator between the bath and the tissues and also required a long time to melt when embedding.

Mouse tissues such as liver, kidney, gut, spleen and pancreas can be dried in seven hours at – 40° C.; but in our hands human tissue (post-mortem) requires twenty-four hours drying for the best results. This need for longer drying times may be due to post-mortem changes, and biopsy material may dry quicker. Fatty materials, such as some skins and also ovary, require a longer drying time. When it is necessary to dry overnight, the cold trap is filled with very finely powdered solid carbon dioxide and a little acetone added. In this way the trap remains cold for at least fourteen hours, whereas the usual acetone/carbon dioxide mush does not last as long. As a precaution against accidents, the apparatus is shielded in use by wire gauze. If short drying times are not essential, the diffusion pump may be dispensed with.

The main advantages of this dryer compared with other recently described designs[2] are its cheapness, robustness and simplicity.

We wish to thank Mr. V. C. Conlay for his helpful criticism.

## The Ratio Molars/Premolars in Perissodactyls

IN the course of a study of the European *Hipparion*[1], it was found that the ratio of the length of the molar series to the length of the premolar series ($M/P$) is fairly constant within that genus. It ranges from 76·7 to 91 ($M/P \times 100$) in thirty-eight specimens of upper tooth-rows from Pikermi and Salonica, most values falling between 80 and 89. It appears to be independent of the length of the tooth-row.

From Osborn's review of the American Equidæ[2], approximate values of the index $M/P \times 100$ have been estimated for the principal members of that family. The first of them (***Mesohippus*** and ***Miohippus***) show some high indices (96–109); but, in those primitive types, if $P^1$ is included in the premolar series, the index falls to the range of values found in more advanced forms (about 78–90) or even lower. Thus, the ratio $M/P$ has tended to remain constant despite the loss of the first premolar; in other words, the series $P^2 + P^3 + P^4$ is playing in later forms the part of $P^1 + P^2 + P^3 + P^4$ in earlier forms (Fig. 1).

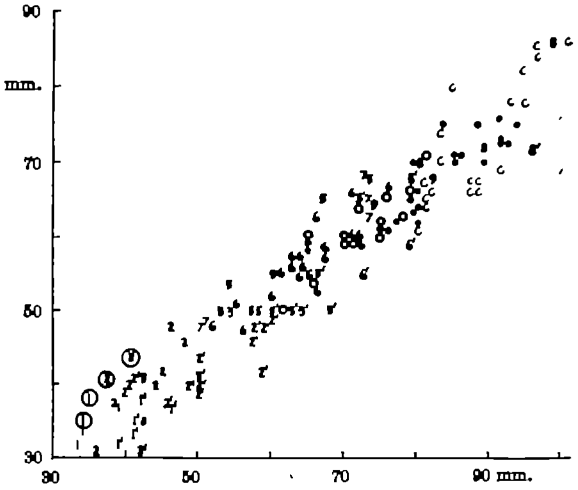

Fig. 1. Ratio molars/premolars in the Equidæ. Ordinate: molars; abscissa: premolars. 1, *Mesohippus*; 2, *Miohippus*; 3, *Kalobatippus*; 4, *Anchitherium*; 5, *Parahippus*; 6, *Merychippus*; 7, *Protohippus*; 8, *Pliohippus*; 9, *Hypohippus*; black dots, *Hipparion* from Pikermi; circles, *Hipparion* from other localities: $C$, *Equus caballus*; 1′, 2′, . . ., as above, but $P^1$ included

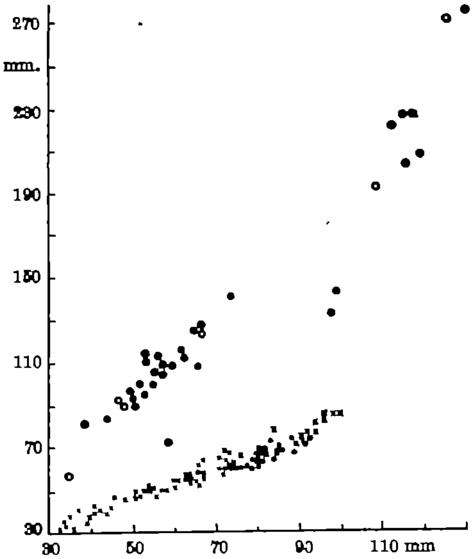

Fig. 2. The same ratio as in Fig. 1 in the Titanotheridæ (circles) and in the Equidæ. Black dots, *Hipparion*. Ordinate: molars; abscissa: premolars

That some individuals of ***Mesohippus*** and ***Miohippus*** have indices higher than 100 suggests that there may have been a trend which has been very soon abandoned by the Equidæ. This earlier trend may have been retained in other families of Perissodactyls. Indeed, in the Titanotheridæ, as described by Osborn[3], the evolution of the dentition has followed a course opposite to that seen in the Equidæ. The index $M/P \times 100$ is always greater than 100, and often reaches about 200. That the two families, at first near each other, have steadily diverged in the course of their respective evolutions, may be shown by plotting the lengths of the series as in Fig. 2.

## Light Emission and Light Perception in Species of *Diadema*

That echinoderms are sensitive to light has been generally agreed, but the nature of their photoreceptors has been the subject of many conflicting statements, sometimes based wholly on inadequate evidence. This is especially so in the echinoids, one family of which, the Diadematidæ, possesses several members which are strikingly sensitive to light[1–6]. Light emission has also been attributed to the species of *Diadema*[1,7], but this has also been questioned[1] and, in the case of *Diadema setosum* (Leske), denied[5].

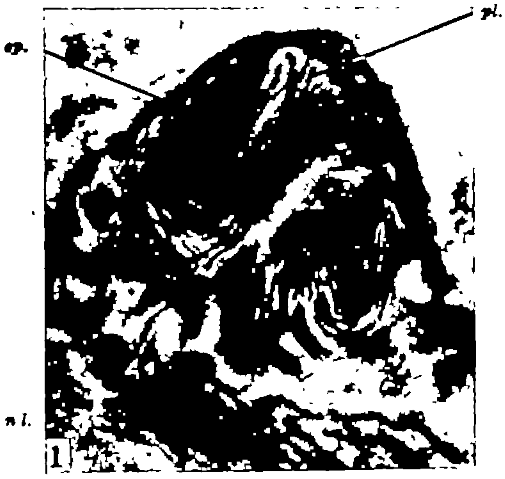
I have examined several hundred individuals of varying ages, of the allied species *Diadema antillarum* Philippi, at various times of the day and year, but I have never seen any signs of phosphorescence. There is a striking iridescence on the test, however, especially in young forms, appearing in bright light as thin lines[8–10] or spots of brilliant blue which correspond closely in distribution with the similar iridescent spots described in *D. setosum*[1,4], and with the areas that have been described as phosphorescent[7].

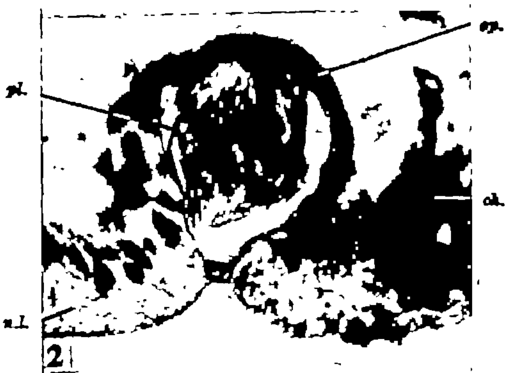
In sections through the test of *D. antillarum*, these areas are distinguished by the presence of the remarkable organs shown in Figs. 1 and 2. Each is composed of single or clustered units containing more-or-less regularly arranged plates (*pl.*) which at once recall those of iridophores[11]. It seems likely that the plates are responsible for the iridescence, which is probably intensified by the dispersion of melanin in the superjacent processes of melanophores (*ch.*).

The blue spots in *D. setosum*, however, have been described as eyes[1,4,5], and to them has been attributed the sensitivity to light. Sarasin, F., and Sarasin, P., have described and figured highly differentiated compound photoreceptors, each unit with cornea, lens and retina[4]. Their ideas have been widely accepted and their figures appear in standard zoological textbooks, despite some hesitancy as to their accuracy[1,12].

In *D. antillarum*, which is extremely sensitive to light[6], I can find nothing corresponding to a lens or a retina in these structures, which are much more reminiscent of clusters of iridophores than of eyes, a suggestion that agrees well with the iridescence observed in the areas where they are located.

Experimental evidence as to the relative sensitivity to light of various parts of the surface gives no support to the idea that these structures are eyes; for, using the production of the spine reflex[6] as an index of sensitivity toward changes in intensity of illumination, it is found that, on obliterating minute light spots projected on to various parts of the surface, the whole surface of the test (including the swollen spine bases) is sensitive to such changes, but the parts bearing the blue lines or spots are much the least sensitive[6]. If, therefore, these are photoreceptors, they are clearly not significantly involved as such in the animal's most striking and characteristic response to light.





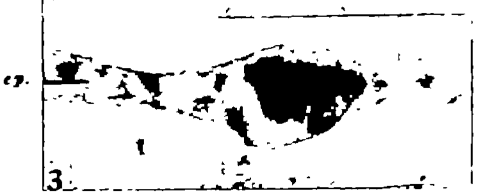


Fig. 1. Vertical section through a cluster of iridophores from a young *Diadema antillarum* (ambital diameter of test, 1·3 cm.), fixed Bouin, stained by Masson's method for the argentaffine reaction, counterstained Mallory's triple stain. Approx. × 500

Fig. 2. Vertical section through a single iridophore of the same individual showing the accompanying melanophore (*ch.*), the contents of which can be seen to have been partly discharged by the action of the fixative. Fixation and staining as above. Approx. × 500

Fig. 3. Vertical section through a developing iridophore from the interambulacrum of a very young *Diadema antillarum* (diameter of test at ambitus, 2·5 mm.). Compare with foregoing and note absence of a recognizable superficial nerve layer. Fixed Bouin, stained Delafield's hæmatoxylin and eosin. Approx. × 500

*ch.*, melanophore; *ep.*, epidermal layer covering test; *n.l.*, superficial nerve layer beneath epidermis; *pl.*, plate-like structure within iridophore

Fully in agreement with this is the recent discovery that a very young form (diameter of test 2·5 mm.), in which the iridescent areas were few and very imperfectly formed (Fig. 3), showed a clear response to shading on the part of the spines, pedicellariæ and suckered tube feet; though it must be admitted that the spine jerks were feeble and lacked the co-ordination characteristic of older forms. Moreover, so far as ordinary histological methods (fixation in Bouin's fluid followed by staining in hæmatoxylin and eosin) may be considered of value, they fail to reveal any direct connexion between many of these organs and the nervous system, for the superficial nerve layer (*n.l.*) so readily demonstrable immediately beneath them in older forms by a similar technique is apparently incomplete and missing from considerable areas of the interambulacra (Fig. 3) which bear these structures. It is highly significant that the absence of special nerves to the organs, in older individuals of *D. setosum*, has been mentioned by authors who regarded them as eyes[4].

For the present, therefore, I find no good reason for regarding these structures in *D. antillarum* as eyes, and in view of the obvious close relationship between *D. antillarum* and *D. setosum*, the matter clearly requires re-investigation in the latter form.

It is suggested that the organs in *D. antillarum* are iridophores, and reflect light on to the neighbouring areas which are more sensitive to changes in light intensity. This function would be especially useful in the deep recesses between the spine bases, and it is here that large masses of them are found. The iridophores would be effective only when the melanin in the chromatophores (which always accompany the iridophores (*ch.*, Fig. 2)) is largely concentrated; for when fully dispersed, the iridophores are covered. This would perhaps, in part, account for the fact that the animal becomes more sensitive to shading as the light fades, for it is then that the melanin becomes concentrated[10]. If the spine reflex is regarded as part of the general defensive reaction set off by the shadow of a potential enemy falling on the light-sensitive surface, the significance of increased sensitivity in fading light becomes obvious.

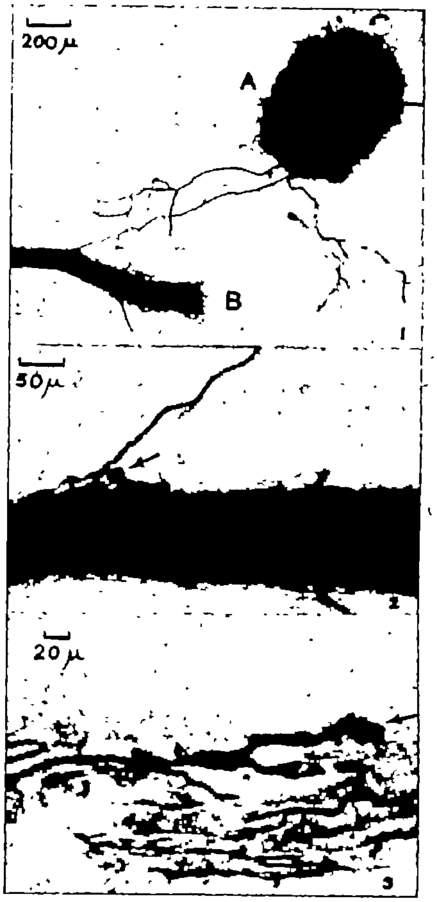
## Fructifications associated with Mycorrhizal Strawberry Roots

ROOT infections by vesicular-arbuscular mycorrhizal fungi have been reported in many plants for more than half a century. With the exception of one unconfirmed report, reproductive stages of these fungi have not been described[1]. Numerous attempts to isolate the fungus from infected tissue have been unsuccessful, and mycelial transplants unattached to a piece of infected plant tissue have never survived[2]. Butler[3] pointed out the close relationship of the vesicular-arbuscular mycorrhizal fungi to the Endogonaceae, and concurred with Peyronel's view that they are probably members of this family.

In 1951, fructifications of the Endogone type were found attached to mycorrhizal strawberry roots grown in pots. The presence of hyphal connexions between these fructifications and the mycorrhizal fungus inside the strawberry roots has been clearly established (Figs. 1–3). The fructifications appear as light-brown spherical bodies, up to 1 mm. in diameter. They consist of a loose weft of hyphæ containing usually two to six, but sometimes up to thirty-two small spores, 92–197 µ in diameter. The spores are distributed at random inside the weft. Mature spores are yellow to brown, with a thick endospore and a thin exospore wall. This, according to Kanouse[4], is a characteristic of the Endogonaceæ.



(1) Hyphal connexion between fructification (*A*) and strawberry root (*B*).
(2) Enlargement of connecting hypha at point of entry into root.
(3) Longitudinal section of the same root showing connecting hypha at point of entry, and its continuity with the mycorrhizal fungus inside the root. Arrows in (2) and (3) mark identical parts of the fungus

Inoculation experiments are in progress to synthesize mycorrhiza under controlled conditions, using the fruit bodies and sterilized spores excised from these to provide the fungus constituent. In these experiments some typical mycorrhizal infections have been obtained in strawberry seedlings grown in test-tubes in soil sterilized by autoclaving and with propylene dioxide. Attempts are also being made to germinate the excised spores on artificial media. The results of these experiments will be reported elsewhere.

## Aggregation in Cellular Slime Moulds: *in vitro* Isolation of Acrasin

In *Dictyostelium* and *Polysphondylium*, members of the Acrasieæ, there is an aggregation stage in which previously independent amœboid cells stream towards certain cell clumps, which thus act as collecting centres, and there form communal fruiting bodies[1]. Communication between the centres and the reacting cells is through the external medium. Bonner[2] produced indirect evidence that a chemical diffused outwards from the centres, setting up a concentration gradient by which the separate cells oriented themselves; pointing out that isolation *in vitro* would be the final proof of the chemical's existence, he named it 'acrasin'.

Pfützner-Eckert[3] claimed that sensitive amœbæ of *D. mucoroides* would move towards a cell-free block of agar on which centres had rested. My own repeated attempts to get orientation to an artificial gradient set up by such an agar block, or by drops of water which had bathed centres and then been absorbed on agar or sucked up a capillary tube, were unsuccessful. Theoretical arguments and experimental observations both suggested that acrasin was short-lived, the active molecules probably having a mean life of a few minutes. If this were so, it would be necessary to renew the head of an artificial gradient at frequent intervals in order to demonstrate orientation. This was finally achieved by sandwiching amœbæ between an agar block and a glass slide; drop by drop, washings from living centres were then rapidly and continually transferred to the meniscus around the block, whence the acrasin they contained diffused into the interior. Chemotaxis now occurred, sensitive cells moving not towards a point, as in normal aggregation, but parallel to each other towards the nearest edge.

To study the stability of acrasin, the washings were kept for short periods before adding them to the meniscus: if kept 1 min., attraction was strong; if 5 min., weak; if 15 min., absent. The washings unavoidably contained a few loose cells from the centres, and there was scarcely sufficient time to remove them by centrifuging; but the fact that the reacting amœbæ, unless they had formed an autonomous organization, became disoriented immediately I stopped adding washings to the meniscus made it unlikely that loose cells which had been carried over were playing any part in setting up the gradient. It was later found that if the washings were frozen within a few seconds of collection their activity was retained indefinitely, though lost as rapidly as before when they were returned to room temperature. No viable cells survived severe freezing.

A test for the presence of acrasin and a means of preserving it made possible a wide variety of experiments. Studies were made of conditions under which acrasin was secreted; the changes in sensitivity of reacting amœbæ; and the rate of decay of acrasin at different temperatures. No evidence could be obtained that acrasin was stored in centres.

As two mixed species of *Dictyostelium* form joint aggregations, whereas when *Dictyostelium* is grown with *Polysphondylium* each genus forms its own[4], it might be expected that acrasin would be genus-specific. I examined *D. discoideum*, *D. mucoroides*, *D. giganteum*, *D. purpureum* and *P. violaceum*. *Dictyostelium* amœbæ of any species responded, as expected, to washings obtained from any *Dictyostelium* centre; but they also oriented themselves to washings from *P.* centres. This seemed to indicate that acrasin was not specific; but further work showed that specific *Polysphondylium*- and *Dictyostelium*-acrasins, which oriented the corresponding cells, did in fact exist. Young *P.* centres and streams made only *P*-acrasin and attracted only *P.* cells. At a certain stage of development, *P.* centres began to make *D*-acrasin too and then attracted both *P.* and *D.* cells; for technical reasons, only centres of this later stage could be bathed to yield acrasin solution, and this oriented both cell types. *D.* centres did not attract *P.* cells, except old ones at short range; probably *D.* centres made only *D*-acrasin, which had a weak effect on specially sensitive *P.* cells. The behaviour of *P.* centres was remarkable, for as they began to make *D*-acrasin their production of *P*-acrasin fell off; that is, they manufactured a foreign chemical, to which most *P.* cells were chemotactically insensitive, apparently at the expense of their own. It may be that *D*-acrasin takes some other role, as yet unknown, in both genera; whatever the explanation, the distribution of sensitivities and powers of synthesis suggest that *Polysphondylium* evolved from *Dictyostelium*; this is consistent with the morphological evidence.

Sussman and Noël[5], and Sussman[6], have shown that initiation of aggregation is a special process, and this confirms my own views based on quite different evidence. Once it is recognized that different acrasins are made at different stages of development, the possibility must be considered that some initiation factors are further slight modifications of the basic acrasin molecule.

## Intolerance of Dizygotic Twin Lambs to Skin Homografts

It has been shown that homografts exchanged between dizygous cattle twins may often survive indefinitely in spite of the fact that grafts exchanged between full siblings other than twins, or between calves and dam, have not been found to survive more than twenty days after transplantation[1,2]. This anomalous tolerance on the part of dizygous cattle twins is thought to have the same origin as their conformity of red-cell agglutination types[3,4], namely, the confluence of their fœtal circulations. The purpose of the present inquiry was to determine whether dizygous sheep twins are also tolerant to grafts of each other's skin.

The same methods were used as have been described for cattle[2]. Pinch grafts were taken from the shaved dorsal surface of the ear and fitted into recesses cut to receive them in a shaved area of the animal's side, just below the withers. The grafts were covered with tulle gras, a layer of sterile gauze and a pad of cotton wool. These dressings were held in place by a 'Lastonet' bandage which completely surrounded the animal. The bandage was secured by rubber latex solution ('Copydex') and Michel suture clips. With cattle, a hessian covering is used for protecting the bandage;

but this was not thought necessary with sheep as their wool seemed to provide sufficient protection. At each operation site, a subcutaneous injection of 2–3 c.c. of 2 per cent ethocaine hydrochloride was given as an anaesthetic.

Two Scottish blackface ewes with twin lambs by a Cheviot ram or rams were available. The ewes were unrelated; but it is possible that all four lambs were half-sibs. The ewes were both about six years old. Ewe 27, dam of lambs ♀2*K*9 and ♂2*K*8, weighed 112 lb. and had lambed on March 29, 1952; ewe 129, dam of lambs ♀2*K*4 and ♀2*K*5, weighed 104 lb. and had lambed on March 26, 1952. All skin interchanges were made on April 30, 1952, when the lambs were about five weeks old.

Four grafts were put on to each animal in a square, thus:

| | |
|---|---|
| 1 | 2 |
| 3 | 4 |

On lambs, position No. 1 was occupied by an autograft, No. 2 by skin from an unrelated ewe, No. 3 by skin exchanged between dam and offspring, and No. 4 by skin exchanged between full-sib twins. On ewes, the arrangement was the same, except that position No. 4 was occupied by skin from the second lamb. The grafts on ewe 27 and her lambs behaved as shown in Table 1. The graft from the unrelated ewe 129 on to lamb 2*K*8 was lost by faulty healing, and the resulting scab obscured the fate of the neighbouring autograft.

Table 1

| Recipients | Donors | | | |
|---|---|---|---|---|
| | Ewe 27 | Lamb 2*K*9 | Lamb 2*K*8 | Unrelated ewe 129 |
| Ewe 27 | + | − | − | − |
| Lamb 2*K*9 | − | + | − | − |
| Lamb 2*K*8 | − | − | ? | lost |

+ indicates survival and − indicates a breakdown in 7–14 days

The parallel series of grafts on ewe 129 and her lambs gave the results shown in Table 2.

Table 2

| Recipients | Donors | | | |
|---|---|---|---|---|
| | Ewe 129 | Lamb 2*K*4 | Lamb 2*K*5 | Unrelated ewe 27 |
| Ewe 129 | Bandage slipped and all grafts lost | | | |
| Lamb 2*K*4 | − | + | − | − |
| Lamb 2*K*5 | − | − | + | − |

Of the six independent autografts, all, except the two lost for technical reasons, survived. At the end of a month they were perfectly established and healthy. That on ewe 27 was particularly well defined, as it consisted of black ear skin and carried a good crop of hair easily distinguishable from wool. The remaining live autografts on the lambs consisted of white ear skin which was less conspicuous but carried white hair instead of wool and were readily differentiated from the scars left by the neighbouring homografts. All homografts broke down rapidly, and fourteen days after the operation only dry scabs remained. It has been assumed that the like-sexed pair is dizygous. This is justified by the established rarity of one-egg twins[5].

These observations make it improbable that, in sheep, homografts between dizygous twins will survive transplantation. Accordingly, skin interchange could be used as a highly critical test for monozygotic twinning in sheep. The intolerance to homografts shown by two-egg sheep twins contrasts with the tolerance shown by two-egg cattle twins, a difference which is no doubt associated with the fact that freemartins occur in cattle but not in sheep.

## Alteration of *p*H in the Sheep's Oviduct

During previous work on the oviduct of the sheep, evidence was obtained which suggested that a change of *p*H might be associated with the cyclical changes of mucin secretion[1] in this duct. In a further investigation the *p*H of the oviducts of seventy sheep, recovered at slaughter from the abattoir, was determined by using Lovibond's comparator. This material covered all stages of the oestrous cycle.

The oviducts were examined within 45–60 min. after death. One oviduct of each animal was washed out with 1 c.c. of double-distilled water, then a further amount of double-distilled water was added to the washing to bring the total amount of liquid to 10 c.c. The first ten oviducts showed a *p*H with the universal indicator between 6 and 7; therefore in all further work bromthymol blue (*p*H 6–7·6) and methyl red (*p*H 4·2–6·3) indicators were employed.

The investigations showed that the *p*H of the oviduct undergoes cyclical change which seems to correspond to the sexual cycle. Where the specimen was clearly in the di-oestrous stage, a *p*H of 6–6·4 was found, in pro-oestrus the *p*H rose to 6·4–6·6 and in oestrus and met-oestrus the *p*H ranged from 6·8 to 7·0. The phase of the cycle was determined by macroscopical examination of the ovary, and in the majority of specimens the follicle or corpus luteum permitted an accurate estimation to be made. In doubtful cases, however, it was found that the *p*H of the oviduct was more reliable than the naked eye diagnosis.

After standing for about two hours, it was found that the *p*H of the specimen fell to 6·2 regardless of the phase of the cycle and the temperature of the refrigerator.

The question arises whether this *p*H has any connexion with the conditioning factor[2] which enables the spermatozoa to penetrate the zona pellucida.

## The Shark, *Isurus oxyrinchus*, in South African Waters

The isurid shark, *Isurus oxyrinchus* Rafinesque, 1810, although most closely related to the Indo-Pacific *I. glaucus* Müller and Henle, 1841, is apparently constantly and clearly differentiated in certain features, notably the height of the dorsal fin and the relative length of the head from snout tip to pectoral origin. Primarily of tropical and subtropical oceanic waters, this species has hitherto been known from a wide range in the Atlantic both east and west. It is extremely virile and vigorous, and is a game fish of repute much sought after by anglers.

Although known in mid-Atlantic at St. Helena, there has hitherto been no positive coastal record from West Africa south of about 12° N. The discovery of a specimen of undoubted *I. oxyrinchus* Rafinesque, off Algoa Bay (about lat. 34° S., long. 26° E.), is therefore of considerable interest. This is obviously a young specimen (see Figs. 1 and 2) which, taken on a line, gave the angler a spectacular fight.

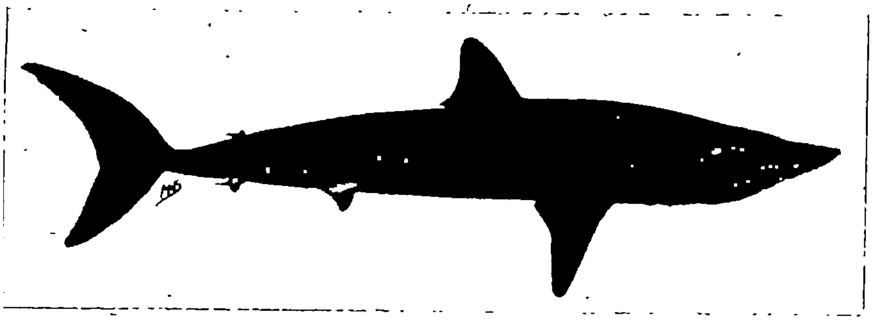

Fig. 1. *Isurus oxyrinchus* Rafinesque, 1810, ♂, 1,130 mm. total length, taken in Algoa Bay, South Africa

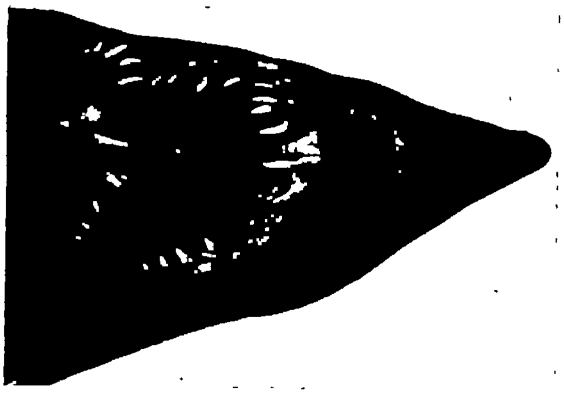

Fig. 2

The specimen is a young male, total length 1,130 mm. The following are percentages of total ength: body to upper caudal pit, 80·0; depth of ody at dorsal origin, 16·4; distance from snout tip o (1) first gill slit, 20·4; (2) pectoral origin, 25·6; 3) first dorsal origin, 38·0; (4) pelvic origin, 56·0; 5) second dorsal origin, 70·3; (6) anal origin, 72·2; 7) line connecting nostrils, 5·1; (8) front of mouth, ·55. The internarial distance, 3·9; diameter of eye, ·6; the interorbital, 6·0; width of mouth (equals eight), 7·6; height of first dorsal, 8·85; its base, ·42; distance from hind margin of eye to fourth ill slit, 17·5.

There are thirteen teeth on each side of each jaw, the third upper smaller, the front two on each side longer and more slender than all others. The body is coloured steel-blue above, white below. Weight 25 lb.

From information since received, it seems that this species may be not uncommon in South African waters.

## Effect of Galvanized Iron on Some Tree Seedlings

It has become usual in Australian forest nurseries to grow tree seedlings in lacquered tin-plate tubes about 6 in. high and 1–1½ in. diameter, which contain sufficient soil for up to two seasons' growth before final planting. A shortage of tin-plate over recent years caused a change to the cheaper and more readily available galvanized iron.

Most varieties appeared unaffected by the change, but some species showed a yellowing of the foliage, stunting of growth and in some cases the death of the seedling after six months or more. Typical species affected are *Acacia spectabilis*, *Callitris cupressiformis*, *Casuarina suberosa*, *Eucalyptus grandis* and *Melaleuca hypericifolia*. For affected species, root growth was normal until the roots reached the tube, when further growth ceased, followed by progressive dying back of the roots until only those running straight downwards remained alive. A similar, but slower, process was seen with the roots of species which appear unaffected above ground, such as *Acacia decurrens*, *Casuarina cunninghamii*, *Eucalyptus saligna*, *Melaleuca bracteata* and *Tristania conferta*. Affected seedlings transplanted in time may recover, and there is some evidence that excessive watering may aggravate the trouble. Rusty tin-plate tubes or uncoated steel tubes, whether rusty or not, are satisfactory.

There have been reports that soils with high zinc contents have given rise to a similar chlorosis with other plants; zinc absorbed by the plant fixes available iron in the tissues so that it is no longer available for biochemical processes. A similar mechanism probably holds for chlorosis in galvanized iron seedling tubes.

In view of the convenience of galvanized sheet or wire as plant containers or protectors, this adverse effect is not so well known as it should be, particularly as there may be some effect not visible above ground. It has also been found that to dip the tubes in bitumen, as a convenient way of covering the zinc, is likely to kill the seedlings in tubes so treated. Experiments being carried out will be published elsewhere later.

We acknowledge the assistance of officers of the New South Wales Forestry Department in providing information and of Mr. E. J. Mansfield in particular, who directed attention to the effect.

## Effects of DDT and BHC on Soil Arthropods

UNDESIRABLE changes in the composition of animal communities after applications of insecticides have become increasingly common phenomena since the widespread use of the more persistent chlorinated hydrocarbons[1]. With the view of throwing further light on this problem, the insecticidal treatment of soil was considered to be a convenient experimental technique, as special attention could be paid to the effects of the insecticides on the dominant soil arthropods, namely, Collembola and Acari.

Replicated plots were treated with (1) 2 oz. per sq. yd. of 2 per cent DDT (75–80 per cent *p,p′* isomer); (2) 2 oz. per sq. yd. of 2 per cent BHC (13 per cent γ isomer); and (3) a combination of these. The insecticides were incorporated to a depth of 9 in., and after treatment the plots were resown with perennial rye grass (*L. perenne*). Samples were taken periodically to a depth of 6 in. and the arthropods extracted with an apparatus similar to that described by Salt and Hollick[2].

The census of total Collembola taken seven months after treatment is of special interest. Treatment totals and the standard error of their differences (all expressed as a percentage of the control population) were:

| DDT | BHC | DDT plus BHC | 0 | S E.* |
|---|---|---|---|---|
| 118 | 76·1 | 106 | 100 | 6 38 |

* 9 d.f., $t = 2{\cdot}26$, $p = 0{\cdot}05$; $t = 3\ 25$, $p = 0\ 01$

A significant increase and a significant decrease in the population of Collembola occurred in the plots treated with DDT and BHC, respectively. The population of the plots receiving both insecticides, however, did not differ significantly from that of the control, but was significantly higher than the population of the plots receiving BHC alone.

In previous investigations, phenomena of this kind have been explained on the basis of predator – prey interaction, and it is probable that the latter may provide an explanation for the results of the present investigation. On the other hand, the results may be wholly or partly explained by the reduction of competition for a common food supply. More conclusive evidence on these points is being sought, and it is hoped to publish a detailed account of the investigation in the near future.

It was also noted that in two of the plots treated with DDT the dominant species included *Tullbergia crassicuspis* Gisin, a species hitherto unrecorded for Britain.

The advice given by Dr. D. S. MacLagan and Mr. M. V. Brian is gratefully acknowledged, and thanks are also due to Miss T. Clay, who identified *T. crassicuspis*.

## Investigation of Nuclear Motion by Electron Diffraction

IT has long been known that the amplitude of nuclear vibrations in free molecules could be studied by electron diffraction if sufficiently accurate intensity measurements were made. Several years ago, Karle and Karle[1] developed the first successful experimental procedure for investigating nuclear motion. Since that time results for a number of molecules have been obtained, both by the Karles and by this laboratory. It is hoped that such information will prove useful in studies of potential fields of molecules, and will also serve to help in the interpretation of diffraction patterns of more complicated molecules with similar interatomic linkages.

In a recent communication in *Nature*, Schomaker and Glauber[2] discussed for the first time the effect of the variation with scattering angle of the phase shift of electron waves scattered by atoms. In particular, they showed that conventional procedures which neglect phase shift on scattering in the interpretation of electron diffraction data may incorrectly deduce an unsymmetrical structure for a symmetrical gas molecule containing a heavy atom.

We should like to point out that atomic phase shifts must be taken into consideration in the calculation of vibrational amplitudes also, even for light atoms. No values in the literature are corrected for this source of error. According to Schomaker and Glauber, the effect upon the molecular intensity is a factor of the form $\cos s\delta$, where $s\delta = |\eta_i(\vartheta) - \eta_j(\vartheta)|$, the phase difference introduced by the scattering processes at the atoms $i$ and $j$.

We note that, if the atoms are light, that is, if $\delta$ is small, Fourier analysis of the molecular diffraction terms for non-rigid molecules including the phase shift factor,

$$|f_i(\vartheta)|\ |f_j(\vartheta)| \cos s\delta \int_0^\infty P_{ij}(r)\ \frac{\sin sr}{sr}\ dr,$$

will lead to an apparent distribution function of the form $\exp\{-(r-r_e)^2/2(\overline{l^2}_{ij}+\delta^2)\}$ for the separation of nuclei $i$ and $j$, rather than the true $P_{ij}(r)$ of the form $\exp\{-(r-r_e)^2/2\,\overline{l^2}_{ij}\}$. The real vibrational amplitude $(\overline{l^2}_{ij})^{1/2}$ can be obtained from the apparent amplitude $(\overline{l^2}_{ij}+\delta^2)^{1/2}$ if $\delta$ is known. Schomaker and Glauber considered the case for $s\delta$ larger than $\pi/2$, in which the apparent distribution splits into two peaks separated by $2\delta$.

The atomic pairs treated by Schomaker and Glauber each contain a fairly heavy atom, and for these pairs $\delta$ is approximately equal to $1{\cdot}8 \times 10^{-3}\,\Delta Z_{ij}$ for 40-kV. electrons. A rough calculation for argon at this laboratory indicates that the formula $\eta(\vartheta)/s \sim 2 \times 10^{-3} Z$ also holds for lighter atoms. If only small differences in atomic number are involved, the apparent amplitude of motion has a relative error of $\sim 2 \times 10^{-4}\,\overline{\Delta Z^2}/l^2_{ij}$. We find then, for example, that the error for a C—F bond is negligible, and the error for a C—Cl bond is about 10 per cent. If $\Delta Z$ is much greater than 10, any information about the associated interatomic spacing which is derived from the shape of the distribution function (such as amplitudes of vibration or restricted rotation or, in extreme cases, type of symmetry) must be regarded with caution unless careful corrections have been made.

Further details and experimental results will be published later.

## Difference between the Density Distribution of Neutrons and Protons in Atomic Nuclei

IN a former communication[1] I calculated the energy and distribution of nucleon density of atomic nuclei by Ritz's method in the first approximation, assuming Yukawa forces between the nucleons. In the energy expression of the nucleus, in addition to the exchange energy and kinetic zero-point Fermi energy of the nucleons, we have also taken into account the kinetic energy correction of Weizsäcker, the electrostatic Coulomb energy of protons and the Coulomb exchange energy of protons arising from the Coulomb interaction of protons. In the first approximation for the neutron density $\rho_n$ and the proton density $\rho_p$, functions of Gaussian type have been set up in the following form:

$$\rho_n(r) = \rho_{n_0} \exp(-a^2r^2/r_0^2), \qquad (1)$$
$$\rho_p(r) = \rho_{p_0} \exp(-a^2r^2/r_0^2), \qquad (2)$$

where $r$ is the distance from the centre of the nucleus, $r_0$ is the Compton wave-length of the $\pi$-mesons divided by $2\pi$, $\rho_{n_0}$ and $\rho_{p_0}$ are normalizing factors and $a$ denotes a variational parameter to be determined from the minimization of the energy.

As a second approximation of Ritz's method, the expressions (1) and (2) have been multiplied by the factor $1 + b(r/r_0)^2$, where $b$ denotes a further variational parameter. By varying the two parameters $a$ and $b$ independently of each other, the energy and the density distribution of the nucleons have been calculated in the second approximation. Thus we have obtained a small energy gain increasing with the mass number, which, however, even for the heaviest nuclei, is smaller than ½ per cent. The change in the nucleon density is also very slight, and except for the outermost boundary areas of the nucleus, only amounts to a few per cent. Thus, in the second approximation the density distribution practically remains a function of the Gaussian type for the heaviest nuclei also. In almost all work on this subject a Gaussian density distribution has been assumed for light nuclei only; for heavy nuclei, however, in the inner parts of the nucleus a constant nucleon density has been assumed, which rapidly decreases on the boundary of the nucleus. Although our variational densities in the second approximation are sufficiently general to represent such a distribution, in spite of this the nucleon distribution we obtain from the minimization of the energy is a Gaussian-type function also for the heaviest nuclei.

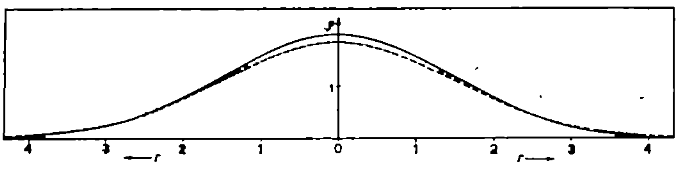

Fig. 1. Neutron density $\rho_n$ (———) and proton density $\rho_p$ (- - - - -) in the nucleus $A = 200$, $N = Z = A/2$. $r$ in $r_0$ units, $\rho_n$ and $\rho_p$ in $1/r_0^3$ units

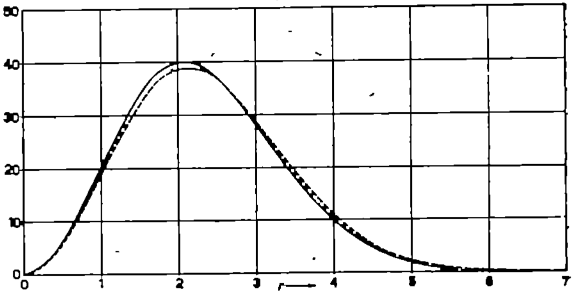

Fig. 2. Radial neutron density $D_n$ (———) and radial proton density $D_p$ (- - - - -) in the nucleus $A = 200$, $N = Z = A/2$. $r$ in $r_0$ units, $D_n$ and $D_p$ in $1/r_0$ units

In all these calculations the variations of the neutron and proton density have not been carried out independently of each other. Except for the normalization factors, which are in general different, both density functions have been assumed to be equal, both of them containing the same variational parameters. As the next step of Ritz's method, both the neutron and proton density have been varied independently of each other. Thus we have obtained a further slight energy gain increasing with the mass number, and being also for the heaviest nuclei smaller than 1 per cent. Between the neutron and proton density a comparatively small difference results. As was to be expected, due to the Coulomb repulsion, the protons are pushed somewhat towards the boundary of the nucleus. The curves of the neutron and proton density, as well as those of the radial densities $D_n = 4\pi r^2\rho_n$ and $D_p = 4\pi r^2\rho_p$, are represented in Figs. 1 and 2 respectively, the difference between the two density functions being more distinctly shown in the latter. As can be seen in Fig. 1, the density functions are still of the Gaussian type. Accordingly, nothing suggests in our case the tendency to form a hole in the centre of the nucleus, resulting from the Coulomb repulsion of protons, as found by Feenberg[2].

The density distributions of the nucleons determined in this way can be used to calculate various nuclear properties and constants. Thus they have been applied to calculate the angular momentum distribution of nucleons. We have obtained for the neutron and proton numbers, at which an *s*-, *p*-, *d*-, *f*-, *g*-, *h*-, *i*-, . . . neutron or proton appears in the nucleus for the first time: 1, 2, 8, 20, 42, 74, 119, . . . . These numbers are in good agreement with the corresponding neutron and proton numbers 1, 3, 9, 21, 41, 71, 113, . . . obtained from the wave-mechanical shell model[3].

A more detailed account of these calculations will be given in the *Acta Physica Hungarica*.

## Wave Hypothesis of Moving Irregularities in the Ionosphere

THE existence of moving irregularities in ionospheric regions has been demonstrated by a number of workers using a wide variety of radio techniques[1], and information regarding their properties is accumulating rapidly. The motions are frequently described in terms of 'winds'; but, as has been repeatedly stressed, the observations need not imply any large-scale movement of the atmosphere. Indeed a number of fairly general considerations can be advanced in support of an alternative view, that a propagated wave-like disturbance is the cause. At the suggestion of Mr. J. A. Ratcliffe, I have begun a theoretical examination of the magneto-hydrodynamic effects involved in such an interpretation.

It is found that travelling atmospheric disturbances, governed by pressure oscillations and gravitational forces, will be accompanied by electromagnetic oscillations which can, under special resonant conditions, become large. The corresponding amplification of the associated electron motions would render such disturbances particularly susceptible to detection by radio methods. Gravity tends to confine the movement of these disturbances to the horizontal plane, though a vertical component is introduced by the effects of cross-conductivities and temperature inhomogeneities. If these, and similar complications, are neglected, it is found that conditions are particularly favourable for disturbances of quasi-period

$$\tau \sim 2\pi \sqrt{2/\gamma(\gamma - 1)}\, C/g, \qquad (1)$$

and group speed

$$V_G \sim C \sqrt{(\gamma - 1)/2\gamma}, \qquad (2)$$

in which $\gamma$ is the ratio of specific heats, $C$ the speed of sound, and $g$ the acceleration due to gravity. No preferred directions of travel relative to the earth's magnetic field appear at this stage, but they can be introduced, in some circumstances, by taking detailed account of electron motions and cross-conductivity effects.

It is natural to associate these resonant oscillations with the large-scale $F_2$-region disturbances observed by Munro[2], in which the numerical density of electrons may change by as much as 25 per cent. They appear to have a fundamental motion in the horizontal plane, with a secondary vertical component superimposed, in agreement with the theoretical predictions. Again, the larger amplitudes and shorter fractional durations (relative to $\tau$), associated by Munro with longer periods, receive plausible explanation in terms of varying resonance conditions.

If typical values for these disturbances, say, $\tau \sim 25$ min. and $V_G \sim 7$ km./min., are inserted directly in (1) and (2), the estimates $\gamma \sim 1 \cdot 1$ and $C \sim 35$ km./min. result. The corresponding temperature ($\sim 1{,}000°$ K.) is in good agreement with other estimates for this region, but the specific heat ratio is appreciably lower than one would expect from the usual considerations. Martyn[3], however, was led to a similar result when considering the bounding of ionospheric disturbances, and he pointed out that low values of $\gamma$ might well occur in regions where ionization was taking place. In any event, (1) and (2) do not take into account a number of factors which will be operative in practice, and so should only be considered as order-of-magnitude relations; as such, they appear to be quite satisfactory.

Favourable conditions are also obtained when

$$\tau \sim 2\pi \sqrt{2/\gamma}\, C/g, \quad V_G \sim C/\sqrt{2\gamma}, \qquad (3)$$

but these values do not appear to correspond to any disturbances so far reported.

No detailed analysis of the higher-frequency radio-star and $E$-region fluctuations has been undertaken as yet; but they appear amenable to a wave interpretation, and many of their properties can be profitably discussed on this basis.

In view of its potentialities and initial successes, the wave hypothesis might well be kept in mind when further analyses of the experimental data are undertaken.

This investigation, which is continuing, is supported by the National Research Council of Canada through a special scholarship. Full details are to be published at a later date.

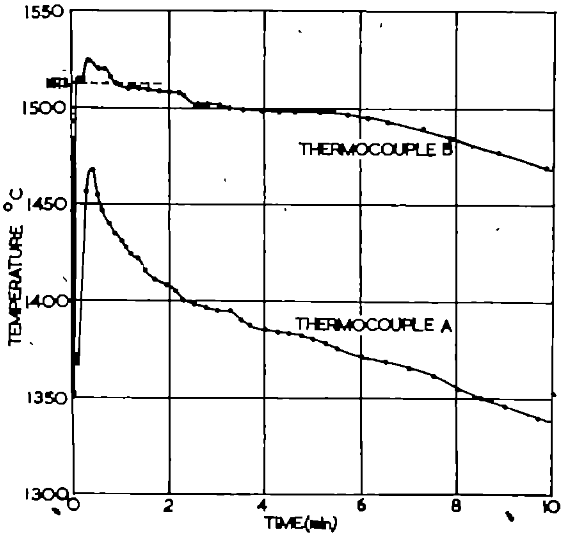
## Measurement of Temperatures of Metal/Mould Interfaces

MANY workers have attempted to observe metal/mould interface temperatures in metal castings by means of thermocouples with sheathed hot-junctions. However, since the temperature gradient in the refractory sheath is high, such measurements are liable to considerable error. We have therefore made measurements on an experimental steel casting with an unsheathed platinum / platinum - 13 per cent rhodium hot junction, the metal of the casting being used as intermediate metal; the two wires were simply pushed through the mould wall some 0·3 cm. apart. The technique has the following advantages: (i) it eliminates errors due to the temperature gradient across the sheath; (ii) it minimizes thermal lag; (iii) it ensures accurate location of the hot junction at the metal/mould interface, since the hot junction is formed at the points where the molten metal comes into contact with the thermocouple wires.



The temperatures recorded at the interface in the base of a 280-lb. low-carbon steel casting during the first 10 min. after pouring are shown in the accompanying graph, where the 'intermediate metal' thermocouple (*B*) is compared with a conventional thermocouple (*A*) of which the sheathed butt-welded hot junction lay in the plane of the metal/mould interface. The metal liquidus temperature of 1,518° C., shown on the graph, was determined in an independent laboratory experiment. The comparison shows that the initial chilling and subsequent remelting of the first metal to be poured are clearly recorded by *B*, but not recorded at all by *A*, owing to the temperature gradient in its sheath and its marked thermal lag. Also the temperatures recorded by *A* throughout are much lower than those of *B* because of the temperature-gradient error. Calibration of *B* before and after the experiment showed that errors due to contamination were negligible.

The method may have wider application than the one described. A detailed account of the use of the thermocouple will be published elsewhere.

## Oat Lipase and Tributyrin

OAT lipase is located in the outer pericarp layers of the groat and can be removed by wet-brushing[1]. Using this technique with 20 gm. of groats per 100 ml. distilled water, a suspension is obtained which contains c. 98 per cent of the total active lipase. From such extracts oat lipase has been purified approximately 1,700-fold on a dry weight basis compared with the original activity in oatmeal.

The lipase activity has been measured by two methods: (*a*) a 'dough' method using olive oil as substrate[2]; (*b*) a manometric method[3] using tributyrin as substrate in a bicarbonate – carbon dioxide buffer system at $pH$ 7·4. Although the substrates are not interchangeable, that is, the lipase will not hydrolyse tributyrin in the 'dough' method nor olive oil in the manometric method, the same enzyme is thought to be responsible for both activities, since the ratio of the activities against the two substrates remains the same during the various stages in the purification of the enzyme.

The difficulties of differentiating lipase and esterase activities have been discussed by Desnuelle *et al.*[4], and it is generally considered that tributyrin hydrolysis is effected by a true lipase; in the case of milk, the tributyrinase and lipase activities have been definitely correlated[5].

In the course of a study of the kinetics of the purified enzyme using the manometric method with tributyrin at low substrate concentrations and $pH$ 7·4, the reaction was observed to cease when only a third of the total possible carbon dioxide had been evolved. This suggested that the purified lipase was only splitting off one butyric acid radical, leaving a dibutyrin as a reaction product. Krebs's pots were set up and the product of reaction (*X*) was isolated as a faintly yellow oil, boiling point 185–7°/26 mm., giving a negative periodate-fuchsin reaction; analysis gave C 56·71 per cent, H 8·52 per cent and saponification value 478 (calculated for dibutyrin, 56·86 per cent, 8·68 per cent and 483, respectively).

This suggests that the hydrolysis of the triglyceride by the purified lipase involves the splitting off of only one fatty acid radical and not a complete hydrolysis to glycerol and free fatty acid. Further evidence supporting this interpretation of the mode of action has been obtained by testing the activity of the purified lipase against the other compounds of glycerol and butyric acid. α-Monobutyrin was prepared by the method of Schuette and Hale[6], β-monobutyrin by the method of Daubert[7], and the two dibutyrins were prepared from the corresponding dibromhydrins by heating in sealed tubes with sodium *n*-butyrate as described by Guth[8]. The accompanying table gives the analytical data for these compounds.

These four compounds, together with *X* and tributyrin, were set up at 37° in manometers against a freshly prepared, purified lipase (3·3 mgm. substrate per flask, 0·0148 *M* sodium bicarbonate $pH$ 7·4, total vol. 3 ml., gas phase 5 per cent carbon dioxide/95 per cent nitrogen) together with appropriate boiled enzyme blanks. Lipolysis was only observed with tributyrin, the reaction being complete after 45 min. when one-third of the total possible carbon dioxide had been evolved. Thus under these conditions lipase is unable to hydrolyse either the di- or mono-butyrins, and attacks tributyrin by removing one fatty acid chain only. From the boiling point of *X* it would appear probable that the β-linkage is the one specifically hydrolysed and that *X* is in fact αγ-dibutyrin.

A high production of diglyceride has been observed with certain preparations of pancreatic lipase[4,9], and Frazer (see ref. 9) has suggested that more than one enzyme may be involved in the complete hydrolysis of a triglyceride. This, however, appears to be the first direct demonstration, with a lipase preparation acting upon a triglyceride, that only one fatty acid radical is specifically split off.

## A New Spraying Agent for Paper Chromatography of Carbohydrates and Polyols

While investigating the chromatographic separation of sugars upon filter paper impregnated with sodium borate buffer (0·05 *N* borax, *p*H 9·18) it was found that the carbohydrates showed up prominently on spraying with 80 per cent aqueous ethanol containing either 1 mgm./ml. of phenolphthalein or phenol red just made alkaline with sodium hydroxide. Phenolphthalein gave rise to white spots on a purple background and was rather more effective than phenol red, which gave yellow spots on a purple background.

It was considered that the change in *p*H consequent upon the formation of carbohydrate–borate complexes might be used directly. Preliminary studies led to the development of a spraying reagent consisting of 1 part 0·05 *N* sodium borate (*p*H 9·18), 2 parts phenol red (2 mgm./ml. in ethanol made just alkaline with sodium hydroxide) and 7 parts methanol. The reagent could also be made up in ethanol. This, however, caused some precipitation of borate, which might lead to variability of performance, although the ethanolic reagent has given uniformly good results in our hands. Phenolphthalein was an inferior substitute for phenol red, as the reagent had to be adjusted to such a *p*H that it just coloured the paper. This proved awkward and, since the indicator did not always spread evenly, owing apparently to adsorption on the paper, phenolphthalein is not recommended.

Although we have experienced no trouble from this cause, it should be noted that acidic or basic substances able to move in the solvents used might interfere. These could be removed by ion exchange resins. The method has, however, proved more satisfactory than the use of ammoniacal silver nitrate. Methanolic phenol red – borate gave good definition with 25–50 μgm. dihydroxyacetone, arabinose, xylose, fructose, glucose, lactose, mannose, sucrose, maltose, cellobiose, raffinose and a number of polyols.

Ascending chromatography on Whatman No. 4 paper was carried out for 15 hr. using developing solvents similar to those described by Jeanes, Wise and Dimler[1]. The distances moved by glucose were about 9·5 cm. in solvent *B* and 4·5 cm. in solvent *F*. Typical *Rg* values are quoted in the accompanying table for some polyols.

The method may also be of value when it is necessary to determine the position of sugars by a technique that leaves them unchanged, so as to make possible leaching out the spots for micro-determinations.

$$Rg = \frac{\text{distance moved by substance}}{\text{distance moved by glucose}}$$

| Solvent | *B* *n*-Butanol : pyridine : water = 3 : 2 : 1·5 | *F* *n*-Butanol : pyridine : water = 4 : 1 : 1 |
|---|---|---|
| Dihydroxyacetone | 1·84 | 3·38 |
| Glycerol | 1·61 | 2·58 |
| Erythritol | 1·35 | 1·85 |
| Mannitol | 0·91 | 0·92 |
| Sorbitol | 0·92 | 0·87 |
| *i*-Inositol | 0·39 | 0·19 |

Reference has been made by Bradfield and Flood[2] in a communication entitled "Soluble Carbohydrates of Fruit Plants" to the use of borate buffer containing bromcresol purple for similar purposes to the above.

## Serological Activity of Globulin Fractions of Anti-*D* Sera separated by Paper Electrophoresis

It seems that the existence of blocking, incomplete (non-blocking) and complete (saline) antibodies is generally accepted; but up to now little work has been done to widen our knowledge about serological activity of different fractions of anti-*Rh* sera containing those kinds of antibodies.

After preliminary examination of many immune sera, three anti-*D* sera were chosen. All these sera are very close to each other from the point of quantitative serological reaction, but at the same time they show marked differences in respect of the qualitative behaviour of anti-*D* antibody in carrying out various serological tests. The sera used are: No. 1286, containing blocking antibody (blocking titre 1/16, trypsin titre 1/32, albumin titre 1/16, saline titre negative, indirect *AHG* titre 1/128); No. 23530 with incomplete (non-blocking) antibody (blocking titre negative, trypsin titre 1/64, albumin titre 1/16, saline titre negative, indirect *AHG* titre 1/256); and No. 11871 with saline antibody (blocking titre negative, trypsin titre 1/64, albumin titre 1/64, saline titre 1/16, indirect *AHG* titre 1/128).

Electrophoresis on filter-paper strips (Whatman No. 2, 37 cm. × 5 cm.) was carried out to isolate $\alpha_1$-, $\alpha_2$-, β- and γ-globulin. The apparatus described by Flynn and de Mayo[1] was used with barbitone buffer *p*H 8·6; potential 350 V., for 3 hr., current 0·4 m.amp./cm. width.

In all experiments seven strips were used for each serum to be investigated; 0·03–0·04 ml. of serum was placed on each strip in a straight line 4 cm. long by means of a capillary glass pencil. After each run the strips, still wet, were cut into two parts and one of 37 cm. × 1·5 cm. was dried and stained with a solution of 1 per cent bromphenol blue in 95 per cent ethyl alcohol saturated with mercuric chloride. The strips were then washed in running tap water. The coloured strips were used for detecting the exact position of the different globulin fractions on the uncoloured parts of the strips. Each unstained strip was cut into fractions and the different globulins immersed in 1 ml. of saline (for each fraction) and eluted for 16 hr. at + 4° C. The filter paper was removed from the eluate by centrifugation and the eluates were examined, using blocking, trypsin, papain, albumin

| Test | No. 1286 | | | | No. 23530 | | | | No. 11871 | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | $\alpha_1$ | $\alpha_2$ | $\beta$ | $\gamma$ | $\alpha_1$ | $\alpha_2$ | $\beta$ | $\gamma$ | $\alpha_1$ | $\alpha_2$ | $\beta$ | $\gamma$ |

All controls were normal. v, Visible clumps; ++, large clumps visible in microscopic field; +, smaller clumps; w, microscopically weak reaction; −, no agglutination

saline and indirect anti-human-globulin tests. In all experiments the same $OR_1r$ and $Orr$ normal, trypsinized and papainized red cells were used. The results are tabulated herewith.

It is obvious from these results that the blocking, incomplete (non-blocking) and complete (saline) antibodies belong to the γ-globulin fraction of anti-*D* sera. Anti-*D* activity was not found in any other fraction.

We could not confirm the observation of Cann *et al.*[2] that other globulin fractions contain also *Rh* antibodies. It seems to us that it is rather difficult to obtain a clear conclusion from the results obtained by those authors. This discrepancy between the results of Cann and co-workers and our results is probably due to the fact that a better separation of globulin fractions is possible by means of paper electrophoresis than by the electrophoresis convection method.

Serological examinations of different fractions, using different tests, show that the albumin method gives the weakest reactions, whereas the indirect anti-human-globulin test and the tests with trypsinized and papainized red cells give very clear reactions. It is to be noted that some samples of eluates from the γ-globulin fraction of serum No. 1286 show a very weak blocking effect in spite of a satisfactory titre obtained with the indirect *AHG* test.

The use of the paper electrophoresis method for investigating an anti-*D* serum is very simple and gives accurate results. The method can probably be used for immune sera which contain two or more antibodies with different serological specificity. The method is especially convenient for the examination of very rare antisera, since a quantity of about 0·25 ml. is enough to obtain an eluate with good serological activity. The main disadvantage of the paper electrophoresis method is that it is practically impossible to obtain an eluate with the same concentration of antibody as in the original sample of the serum used.

## A Simple Method for the Preparation of Crystalline Potato Phosphorylase and Q-Enzyme

IN the purification of potato phosphorylase[1] by ethanol precipitation[2], it has been found that conditions established for a particular variety of potato, harvested at a particular time of the year, are not generally applicable to other potatoes, even though these may contain as much enzyme. This is because the solubility of the enzyme is affected by its association with other constituents, the nature and quantity of which vary with the type of potato and the season. Since, in spite of this association, the enzyme is always able to react with its substrate, it was thought that the formation of the enzyme substrate complex might be utilized to free the enzyme from these other complexing molecules. Preliminary experiments in which the precipitation of phosphorylase was carried out in the presence of glucose-1-phosphate did not, however, show any appreciable change in the solubility of the enzyme. These experiments were not pursued further after it had been found that the presence of the co-substrate, amylose, results in a strong and selective precipitation of phosphorylase at a concentration of ethanol at which the enzyme is otherwise soluble[3], and in at least a thousandfold purification of the enzyme with respect to protein. The phosphorylase is accompanied in the precipitate by the *Q*-enzyme of the potato[3]. The enzymes are readily extracted from the precipitate and can then be precipitated from solution with ammonium sulphate in crystalline form.

The exact conditions of the preparation do not seem to be critical, and crystalline enzymes have been obtained from four varieties of potato for which the ordinary ethanol precipitation was ineffectual. The following has proved to be a convenient procedure. Freeze-dried potato juice is reconstituted with distilled water and brought at 0° to 11 per cent ethanol concentration with 50 per cent ethanol–citrate reagent[4] (0·282 ml./ml. juice). The precipitate, which contains amylose precipitant, is discarded. A suspension of wrinkled pea amylose[5] in water (0·2 gm./ml.) is boiled for about three minutes, and cooled to 0°. The supernatant liquid is poured into this suspension (2 ml. supernatant/1 ml. suspension) and the mixture brought to 11 per cent ethanol by adding 50 per cent ethanol–citrate reagent (0·094 ml./ml. mixture). After stirring for 10 min. the mixture is centrifuged and the precipitate washed five times, each time with seven times its volume of 11 per cent ethanol containing 0·01 *M*-citrate *p*H 6·0, all these operations being performed at 0°. The precipitate is then extracted twice for 15-min. periods with stirring with three times its volume of 0·05 *M*-citrate *p*H 6·0. The extract is brought to a concentration of 30 per cent w/v ammonium sulphate by adding the appropriate volume of 50 per cent w/v ammonium sulphate (ammonia to *p*H 7·0), and left 1 hr. at 0°. The precipitate, after centrifugation, is extracted with 19 per cent ammonium sulphate solution (0·2 ml./ml. of original juice), to give a solution I and a residue II. Crystalline phosphorylase is precipitated from solution I when this is brought at 0° to 25 per cent w/v ammonium sulphate. Crystalline *Q*-enzyme is obtained by dissolving residue II in 0·05 *M*-citrate *p*H 6·0 (0·2 ml./ml. of original juice) and bringing the solution to 17 per cent w/v ammonium sulphate *p*H 7. The enzymes can be recrystallized from the appropriate ammonium sulphate solutions.

The amount of amylose required per unit volume of juice (for example, 13 per cent w/v above) depends on the previous history of the amylose, and particularly on the extent to which it has retrograded during preparation. The pea amylose used was a rather insoluble alcohol-dried sample. Potato amylose and potato whole starch also adsorb the enzymes under the conditions described; but the use of whole starch is not advocated owing to the complications introduced by its content of amylopectin. A non-retrograded, undried sample of potato amylose was found to adsorb 50 per cent of the phosphorylase of the potato juice when added to the extent of only 3 per cent w/v of the juice. Moreover, the whole of the *Q*-enzyme was adsorbed by 0·15 per cent of this amylose, enabling the *Q*-enzyme to be removed from the phosphorylase at this stage if desired.

Part of the adsorbed *Q*-enzyme is firmly bound to the amylose and cannot be removed with salt solution. It can only be removed by washing the precipitate with starch solution. This suggests that there is a general attraction of the amylose chains for the *Q*-enzyme molecule (presumably through secondary valency forces) leading to a complex which is easily dissociated in salt solution, and that in addition there are a number of sites at which the full enzyme-substrate complex is formed. From these sites the enzyme can be removed only by presenting the substrate in the dissolved form.

It will be noticed that the method of preparation above resembles that used by Schwimmer and Balls[6], who obtained α-amylase from barley by adsorption of the amylase on starch grains from alcoholic solution, and by Hobson, Whelan and Peat[7], who removed *Q*-enzyme irreversibly on potato starch in the preparation of *R*-enzyme.

We wish to thank Prof. H. W. Melville and Prof. M. Stacey for their interest in this work. One of us (H. B.) is indebted to the Department of Scientific and Industrial Research for a maintenance grant.

## A Method of Embedding Brittle Specimens of Wood for Sectioning

GREAT difficulty was encountered in cutting sections from the brittle and often partly carbonized wooden remains found on the sites of Roman and ancient British settlements. The impact of the razor caused instantaneous fragmentation of the sections, and identification became very difficult. A simple embedding material was sought which would penetrate the specimen without difficulty, and which could be cut easily and would prevent the resulting section from crumbling.

A proprietary brand of a polyvinyl lactophenol mixture (that is, polyvinyl alcohol in lactic acid and phenol) was used at first, as it was known that this substance had proved satisfactory in the mounting of entomological specimens without the necessity of previous dehydration. The procedure adopted was as follows. Cubes of the brittle wood are cut in the usual way, with a tangential, a radial and a transverse face; they are then immersed in the polyvinyl lactophenol mixture and warmed gently for half an hour. After removal from the liquid, the cubes were allowed to drain and cool for 24 hr. (It will be found that the cubes are now darker in colour and of a rubbery consistency.) The cubes can then be sectioned with a sharp razor, and the sections mounted directly on to a slide, using the embedding agent as a mounting medium.

The resulting preparation possesses the added advantage of being 'cleared' by the polyvinyl lactophenol. The cell walls, which may be blackened and beginning to undergo carbonization, are rendered clear and translucent, enabling details of structure to be easily observed.

The method has proved to be a quick, easy and efficient one, but possesses certain aspects where care has to be taken. Due to the rubbery nature of the material, sections have to be cut with a sharp razor or else the cube will bend under the impact of the blade. Staining is somewhat difficult, because many dyes tend to diffuse from the sections into the mounting medium[1]. It has proved possible to stick the section to a slide, wash off the polyvinyl lactophenol in hot water, and then to stain, clear and mount up in canada balsam in the usual way, but this technique still requires to be perfected. Some preparations of polyvinyl lactophenol (for example, the proprietary one already mentioned) cause a slight shrinkage to the tissues on drying. Other preparations dry more slowly and so require a longer period at the second and third stages outlined above (for example, Salmon's type *M.A.*1 [2]).

Subsequent search through the literature has shown that this method is not new. Lubkin and Carsten[3] have used a polyvinyl alcohol – glycerine mixture for embedding and sectioning medical pathological material, such as heart, lungs, liver and spleen. Gray and Wess[4] advocate a polyvinyl alcohol – glycerine – lactic acid – acetone mixture for mounting entomological specimens, which has a slightly lower refractive index, but which Brown[5] claims overcomes the tendency to shrink and sets harder than other preparations. These preparations and others are being tested and may well eliminate some of the difficulties in the technique mentioned. Even with these disadvantages, the ease and quickness of embedding and mounting the material should commend itself as a useful method, especially where speed in identification of specimens is an important consideration.

OIL AND COLOUR CHEMISTS' ASSOCIATION (at Eastbourne).—Biennial Conference.

### Thursday, June 4

BRITISH PSYCHOLOGICAL SOCIETY, INDUSTRIAL SECTION (in Room 105, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 1 p.m.—Mr. H. W. Thiele: "A Study of the Occupational Achievements of a Group of Adults Educated at certain Schools for the Blind".

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Meeting to commemorate the Present-day Aspects of the Work of Sir William Ramsay.

### Friday, June 5

PRESENTATION OF TECHNICAL INFORMATION, DISCUSSION GROUP (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 6 p.m.—Dr. P. M. Woodward: "Information Theory".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. M. F. Perutz: "Glaciers".

### Saturday, June 6

BRITISH PSYCHOLOGICAL SOCIETY (in the Psychology Department, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Mr. H. M. B. Hurwitz: "Frustration in Learning, an Account of some Experiments".

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Neville Hall, Newcastle-upon-Tyne), at 2.30 p.m.—Mr. A. B. Dawson: "Methane Emission".

---

## APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT (Grade B) IN MATHEMATICS, and an ASSISTANT (Grade B) IN PHYSICS—The Principal, Derby Technical College, Normanton Road, Derby (June 6).

HEAD OF THE CHEMISTRY DEPARTMENT—The Principal, North Staffordshire Technical College, Stoke-on-Trent (June 6).

LECTURER or ASSISTANT LECTURER IN GEOGRAPHY—The Registrar, University College, Leicester (June 6).

PHYSICAL CHEMIST (with good honours degree, and thoroughly interested in the theory and experimental techniques associated with corrosion research) IN THE BOILER CORROSION RESEARCH LABORATORY, St. John's Wood, London—The Director of Establishments, British Electricity Authority, Winsley Street, London, W.1, quoting A.E.379 (June 8).

SENIOR ASSISTANT ENGINEER (turbines) for general investigations into turbine design problems including the effect of cycle conditions on performance, the preparation of specifications and the critical assessment of the technical features and performance of particular designs, IN THE GENERATION DESIGN BRANCH, Headquarters—The Director of Establishments, British Electricity Authority, Winsley Street, London, W.1, quoting T/381 (June 8)

ASSISTANT LECTURER IN THE DEPARTMENT OF AGRICULTURE (Crop Husbandry)—The Registrar, University College of Wales, Aberystwyth (June 10).

WELLCOME RESEARCH FELLOW for research in connexion with veterinary science or practice—The Scientific Director, Animal Health Trust, 232–235 Abbey House, Victoria Street, London, S.W.1 (June 10).

SENIOR LECTURER IN MECHANICAL ENGINEERING, LECTURERS (2) IN MECHANICAL ENGINEERING, a LECTURER IN PHYSICS, a LECTURER IN RADAR AND TELECOMMUNICATIONS, and DEMONSTRATORS IN MECHANICAL AND ELECTRICAL ENGINEERING, at the Royal Military College of Science, Shrivenham—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4211/53 (June 12).

DESIGN ENGINEERS to assist on design problems of control and nstrumentation for new types of reactors (Ref. D.186/53A), an ENGINEER (mechanical) to work on mechanical design and specification of new types of reactors (Ref. C.252/53A), and ENGINEERS (electrical) to assist design, planning, construction of electric plant and services for large new project (Ref. D.187/53A); in the Ministry of Supply at Harwell—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No. (June 13).

PRINCIPAL SCIENTIFIC OFFICER (with University degree with first- or second-class honours in mathematics or physics or an equivalent qualification, and at least three years postgraduate or other approved xperience in astrophysics, preferably with some experience in line ntensity spectrophotometry) at the Royal Observatory, Edinburgh—he Establishment Officer, Scottish Home Department, Room 364, St. Andrew's House, Edinburgh 1 (June 15).

SHELL SCHOLARSHIPS IN CHEMICAL ENGINEERING—The Registrar, mperial College of Science and Technology, South Kensington, London, S.W.7 (June 16)

GUIDE-LECTURERS (2) (with university honours degree; experience in lecturing or teaching essential, and a sound knowledge of French and at least one other European language desirable) at the British Museum, Bloomsbury—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting 4208/53 (June 18).

LECTURER IN MATHEMATICS (with special qualifications in applied mathematics)—The Registrar, The University, Manchester 13 (June 20).

NUFFIELD FELLOWSHIPS (2) IN THE DEPARTMENT OF PHYSICS in connexion with research on the structure of crystalline proteins—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (June 20).

UNIVERSITY DEMONSTRATOR IN ORGANIC CHEMISTRY—Dr. F. B. Kipping, Chemical Laboratory, The University, Cambridge (June 20).

CHAIR OF BOTANY at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 22).

CHAIR OF CHEMISTRY in the Durham Division of the University of Durham—The Registrar, University Office, 46 North Bailey, Durham (June 22).

CHAIR of ELECTRICAL ENGINEERING at the Imperial College of Science and Technology—The Academic Registrar, University of London. Senate House, London, W.C.1 (June 23).

ASSISTANT EXAMINERS (3) (with such training in chemistry and physics as will enable them to make tests to detect faults in paper, stationers' sundries, etc., supplied for the Public Service) IN H.M. STATIONERY OFFICE—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting 205/53 (June 25).

APPLIED MATHEMATICIAN (preferably with experience in the application of statistical methods or in modern computational methods) in the National Physical Laboratory, Pretoria—The South African Scientific Liaison Officer, Africa House, Kingsway, London, W.C.2 (Pretoria, June 27).

RESEARCH OFFICER (with sufficient background and research experience in colorimetry and/or photometry) IN THE OPTICS SECTION of the National Physical Laboratory, Pretoria—The South African Scientific Liaison Officer, Africa House, Kingsway, London, W.C.2 (Pretoria, June 27).

ASSISTANT (Experimental Officer grade) IN THE PATHOLOGY DEPARTMENT, to work on selection and indexing of fruit stocks for virus infection, and assistance with experimental work on plant virus diseases—The Secretary, Scottish Horticultural Research Institute, Mylnefield, Invergowrie, Dundee (June 30).

ASSISTANT LECTURER or LECTURER (preferably with experience in cytogenetics) IN THE DEPARTMENT OF BOTANY—The Registrar, The University, Liverpool (June 30).

ASSISTANT EDUCATIONAL PSYCHOLOGIST (woman) (with honours or research degree in psychology, and experience in teaching) to the Child Guidance Clinic and Bristol Schools—The Chief Education Officer, Council House, College Green, Bristol 1.

ASSISTANT LECTURER (with honours degree in geology, and preferably some research experience in stratigraphy and palæontology) IN GEOLOGY—The Secretary, University College, Gower Street, London, W.C.1.

ASSISTANT LECTURER (with good honours degree) IN PHYSICS—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

ASSISTANT SUPERINTENDENT (Senior Scientific Officer grade) (professional/academic qualifications and administrative ability essential; thorough knowledge of the use and testing of textile and related materials used on railways required) IN THE TEXTILES DIVISION of the Research Department, Derby—The Director of Research, Railway Executive, 222 Marylebone Road, London, N.W.1.

CURATOR (with university degree in anthropology or archæology) OF THE ZANZIBAR MUSEUM—The Director of Recruitment (Colonial Service), Colonial Office, Great Smith Street, London, S.W.1, quoting CDE.167/1C/01.

DEMONSTRATOR IN BOTANY, and a DEMONSTRATOR IN ZOOLOGY (with good honours degree in botany, agricultural botany, or zoology) IN THE DEPARTMENT OF BIOLOGICAL SCIENCE—The Registrar, Wye College, Ashford, Kent.

LECTURER IN ELECTRICAL ENGINEERING (with honours degree in electrical engineering, and some practical experience)—The Professor of Electrical Engineering, Imperial College of Science and Technology, Exhibition Road, London, S.W.7.

LECTURER IN ELECTRICAL ENGINEERING (electronics) (with honours degree in physics or electrical engineering, and experience in airborne radio and radar systems, servomechanisms, or electronic techniques in measurement and control) to cover fundamental electronic circuits, including pulse circuits and their application to the measurement of non-electrical quantities—The Recorder, College of Aeronautics, Cranfield, Bletchley, Bucks.

LECTURERS and ASSISTANT LECTURERS IN (*a*) APPLIED MECHANICS, (*b*) HEAT ENGINES, and (*c*) ENGINEERING DRAWING, IN THE DEPARTMENT OF CIVIL AND MECHANICAL ENGINEERING—The Secretary, Royal Technical College, Glasgow.

REGIONAL TRIALS OFFICER (with degree in botany or agriculture or equivalent qualification, and practical experience in crop production) for work possibly at Newcastle—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge

RESEARCH STUDENT (with some biochemical experience, and preferably with a knowledge of tissue slice techniques) IN THE CANCER RESEARCH DEPARTMENT, to work on problems concerning the mechanism of enzyme synthesis—The Secretary, London Hospital Medical College, Turner Street, London, E.1.

SCIENTIFIC OFFICER (Grade 1) and a SCIENTIFIC OFFICER (Grade 2) to work on behalf of the British Transport Commission on problems of friction and adhesion, at the Mechanical Engineering Research Organization, East Kilbride—The Director of Research, Railway Executive, 222 Marylebone Road, London, N.W.1.

---

## REPORTS and other PUBLICATIONS

*(not included in the monthly Books Supplement)*

### Great Britain and Ireland

Report to the Boiler Availability Committee by the Burton Investigation Group on the Relationship between the Chlorine Content of the Coal Burned and the Availability of a Stoker Fired Boiler at the Burton Generating Station of the British Electricity Authority East Midlands Division. (Bulletin MC/233. Technical Paper No. 3.) Pp. 51. Second Interim Report on External Deposits and Corrosion in Boiler Plant, 1946–1951. (Bulletin MC/234.) Pp. 31. Summaries of Published Papers. (Bulletin MC/235.) Pp. 24. Bibliography of

Papers relating to the External Fouling and Corrosion of Boiler Plant, 1940–1951. (Bulletin MC/236.) Pp. 27. (London: Boiler Availability Committee, 1953.) [263

Memoirs of the Geological Survey of Great Britain. The Mesozoic Ironstones of England—The Liassic Ironstones. By T. H. Whitehead, W. Anderson, Dr. Vernon Wilson and Dr. D. A. Wray; with Contributions on Petrography, by Dr. K. C. Dunham. Pp. viii+211+8 plates. (London: H.M. Stationery Office, 1952.) 25s. net. [303

Royal Institute of International Affairs. Information Papers No. 18: World Production of Raw Materials. New and revised edition. Pp. viii+104. (London and New York: Royal Institute of International Affairs, 1953.) 7s. 6d. net. [313

Library Association: Reference and Special Libraries Section (South Eastern Group). Library Resources in the Greater London Area, No. 2: Photographic Literature; a Symposium. Pp. 20. (West Wickham: Miss O. T. Smith, Hon. Secretary, 230 Queensway, 1953.) 2s. 9d.; to Members, 2s. [313

Lundy Field Society. Sixth Annual Report, 1952. Pp. 62+2 plates. (Exeter: Dr. A. Harvey, Secretary, University College, 1953.) 2s. 6d. [14

Chelsea Polytechnic. Fifty-seventh Annual Report, Session 1951–52. Pp. 32. (London: Chelsea Polytechnic, 1953.) [14

Photography and the Amateur Astronomer. By Dr. Gerald Merton. (B.A.A. Reprint No. 1.) Pp. 24+7 plates. (Hounslow: British Astronomical Association, 1953.) 1s. [84

The Production of Barley for Malting. (Monographs on Malt and Malt Products.) Pp. 28. (Bedford: Muntona, Ltd.; Ipswich: Edward Fison, Ltd., 1953.) [84

Department of Scientific and Industrial Research: Food Investigation. Special Report No. 58: Whalemeat; Production and Preservation. By Dr. J. G. Sharp and Dr. B. B. Marsh. Pp. vi+48+4 plates. 2s. 6d. net. Special Report No. 59: Whalemeat; Bacteriology and Hygiene. By R. H. M. Robinson, Dr. M. Ingram, Dr. R. A. M. Case, Dr. J. G. Benstead; with Appendix by Dr. H. E. Daniels. Pp. vi+56. 2s. net. (London: H.M. Stationery Office, 1953.) [84

Anti-Locust Memoir 5: Seasonal Breeding and Migrations of the Desert Locust (*Schistocerca gregaria* Forskål) in South-Western Asia. By J. Fortescue-Foulkes. Pp. 36. (London: Anti-Locust Research Centre, c/o British Museum (Natural History), 1953.) 10s. [84

Transactions of the Royal Society of Edinburgh. Vol. 62, Part 2, No. 12: The Monomyarian Condition in the Lamellibranchia. By C. M. Yonge. Pp. 443–478. (Edinburgh and London: Oliver and Boyd, Ltd., 1953.) 9s. [84

Thirty-second Annual Report of the E.R.A. for the period ended 31st December, 1952. Pp. 162. (Leatherhead: British Electrical and Allied Industries Research Association, 1953.) [94

Philosophical Transactions of the Royal Society of London. Series A: Mathematical and Physical Sciences. No. 903, Vol. 245: Mass Transport in Water Waves. By M. S. Longuet-Higgins. Pp. 535–581. (London: Cambridge University Press, 1953.) 11s. [94

Commonwealth Bureau of Horticulture and Plantation Crops Technical Communication No. 23: Field Experimentation with Fruit Trees and other Perennial Plants. By S. C. Pearce. Pp. x+131. (Farnham Royal: Commonwealth Agricultural Bureaux, 1953.) 10s. [94

University of Cambridge. Report of the Observatories Syndicate for the Year ending 1952 September 30. Pp. 4. (Cambridge: The University, 1953.) [204

Wye College: Department of Hop Research. Annual Report, 1952. Pp. 70. (Wye: Wye College, 1953.) 4s. [204

British Iron and Steel Research Association. Annual Report, 1952. Pp. 128. (London: British Iron and Steel Research Association, 1953.) [204

Transactions of the Royal Society of Edinburgh. Vol. 62, Part 2, No. 11: Serpentine Lavas—The Ankara Mélange and the Anatolian Thrust. By Sir E. B. Bailey and Prof. W. J. McCallien. Pp. 403–442+8 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1953.) 17s. 6d. [204

## Other Countries

Carnegie Institution of Washington. Year Book No. 51, July 1, 1951–June 30, 1952; with Administrative Reports through December 12, 1952. Pp. xxxv+286. (Washington, D.C.: Carnegie Institution, 1952.) 1 dollar. [313

Ministry for Foreign Affairs of the Polish People's Republic. Documents on the Hostile Policy of the United States Government towards People's Poland. Pp. xii+246+8 plates. (Warsaw: Ministry for Foreign Affairs of the Polish People's Republic, 1953.) [14

East African Industrial Research Board. Technical Pamphlet No. 16: Clays, Red and Black, and Nairobi Building Stone; an Attempt to use them for the Manufacture of Bricks and Tiles. By W. Colet Birch. Pp. 22. (Nairobi: Government Printer, 1953.) 1s. 6d. [14

Smithsonian Miscellaneous Collections. Vol. 121, No. 3: A Revision of the Colombian Species of Monnina (Polygalaceae). By Ramón Ferreyra. (Publication 4100.) Pp. v+59. (Washington, D.C.: Smithsonian Institution, 1953.) [14

Department of Transport: Meteorological Division. Summaries of Radiosonde Observations in Southern Canada, Stations South of Latitude 55° N., June 1941–December 1949. Pp. 149. (Toronto: Department of Transport, n.d.). 1 dollar. [14

United States Department of Agriculture. Farmers' Bulletin No. 1945: The Pea Aphid on Peas and Methods for its Control. By J. E. Dudley, Jr., and T. E. Bronson. Pp. ii+13. 5 cents. Farmers' Bulletin No. 1971: The Pea Weevil and Methods for its Control. By T. A. Brindley, J. C. Chamberlin and Ralph Schopp. Revised edition. Pp. ii+24. 15 cents. Circular No. 906: Improvements in the Control of Ribes by Chemical and Mechanical Methods. By H. R. Offord, V. D. Moss, W. V. Benedict, H. E. Swanson and A. London. Pp. 72+9 plates. 35 cents. Technical Bulletin No. 1036: Parasites of the Lima-Bean Pod Borer in Europe. By Henry L. Parker. Pp. 28. 15 cents. Technical Bulletin No. 1039: Effect of Winter Cover Crops on Wireworm Injury to the Dry Lima Bean Crop. By M. W. Stone. Pp. 20. 10 cents. Technical Bulletin No. 1047: Effect of Soil Treatments with DDT, Benzene Hexachloride and Toxaphene on Tobacco, Cotton and Cowpeas. By Norman Allen and Floyd F. Bondy, J. F. Bullock and R. E. Hall. Pp. 22. 15 cents. Technical Bulletin No. 1052: Classification of the Ortheziidae; Supplement to Classification of Scale Insects of the Subfamily Ortheziinae. By Harold Morrison. Pp. 80. 30 cents. (Washington, D.C.: Government Printing Office, 1951–1952.) [14

Bulletin of the World Health Organization. Supplement 7: Guide for National Studies of Nursing Resources. By Margaret G. Arnstein. Pp. 36. (Geneva: World Health Organization; London: H.M. Stationery Office, 1953.) 0.75 Swiss francs; 1s.; 20 cents. [14

Mededelingen van de Koninklijke Vlaamse Academie voor Wetenschappen, Klasse der Wetenschappen. Jaargang 14, Nr. 12: Het probleem der bevruchting in de loop der tijden. Door Dr. A. Schierbeek. Pp. 30. (Brussel: Koninklijke Vlaamse Academie voor Wetenschappen, 1952.) [14

Publications of the Kapteyn Astronomical Laboratory at Groningen. No. 55: An Investigation on the Eclipsing Binaries brighter than Photographic Magnitude 8.50 at Maximum. By L. Plaut. Pp. iii+62. (Groningen: Verenogde Drukkerijen Hoitsema N.V., 1953.) [14

United States Department of Agriculture. Miscellaneous Publication No. 273: Insect Enemies of Western Forests. By F. P. Keen. Revised edition. Pp. 280. (Washington, D.C.: Government Printing Office, 1952.) 1 dollar. [14

Scientific Institutions and Scientists in Latin-America. Cuba, Vol. 1. Pp. iv+96. (Montevideo: Unesco Centro de Cooperacion Cientifica para America Latina, 1953.) [14

Carnegie Institution of Washington. Annual Report of the Director of the Department of Terrestrial Magnetism. (Reprinted from Carnegie Institution of Washington Year Book No. 51.) Pp. 65–98. (Washington, D.C.: Carnegie Institution, 1952.) [14

Annals of the New York Academy of Sciences. Vol. 56, Article 2: Comparative Conditioned Neuroses. By Edward J. Kempf and 16 other Authors. Pp. 141–379. (New York: New York Academy of Sciences, 1953.) 3.50 dollars. [14

State of California: Department of Fish and Game. Forty-second Biennial Report of the Department of Fish and Game for the Years 1950–1952. Pp. 187. (San Francisco: Department of Fish and Game, 1953.) [14

Smithsonian Miscellaneous Collections. Vol. 121, No. 1: Geology of the San Jon Site, Eastern New Mexico. By Sheldon Judson. (Publication 4098.) Pp. v+70+5 plates. Vol. 121, No. 13: Regarding Washington, D.C., Precipitation and Temperature, 1952 and 1953. By C. G. Abbot. (Publication 4130.) Pp. ii+7. (Washington, D.C. Smithsonian Institution, 1953.) [14

Bulletin of the American Museum of Natural History. Vol. 100 Article 3: Avian Systematics and Evolution in the Gulf of Guinea: the J. G. Correia Collection. By Dean Amadon. Pp. 393–452+4 plates. 1 dollar. Vol. 100, Article 4. A Generic Revision of Flycatchers of the Tribe Muscicapini. By Charles Vaurie. Pp. 453–538. 1 dollar. (New York: American Museum of Natural History, 1953.) [14

Travaux et Mémoires du Bureau International des Poids et Mesures. Publiés sous les auspices du Comité International par le directeur du Bureau. Tome 21. Pp. vii+458. (Paris: Libr. Gauthier-Villars 1952.) [84

State of California: Department of Fish and Game, Marine Fisheries Branch. Fish Bulletin No. 89. The Commercial Fish Catch of California for the Year 1951, with an Evaluation of the Existing Anchovy Case Pack Requirements. By the Staff of the Bureau of Marine Fisheries. Pp. 68. Fish Bulletin No. 90: Common Marine Bivalves of California. By John E. Fitch. Pp. 102. (San Francisco: Department of Fish and Game, 1953.) [84

University of Illinois Engineering Experiment Station. Bulletin Series No. 403: Comparative Performances of Two Warm-Air Perimeter Systems and Three Convection Systems. By Morris E. Childs, Robert W. Roose, Herbert T. Gilkey and Seichi Konzo. Pp. 55. 60 cents. Bulletin Series No. 404: Gradually Varied Flow in Uniform Channels on Mild Slopes. By Ming Lee, Prof. Harold E. Babbitt and E. Robert Baumann. Pp. 90. 1 dollar. Bulletin Series No. 405 Studies of Slab and Beam Highway Bridges, Part 4, Full-Scale Tests of Channel Shear Connectors and Composite T-Beams. By I. M. Viest, C. P. Siess, J. H. Appleton, and N. M. Newmark. Pp. 155. 1 dollar. Circular Series No. 65: An Electric Recording Water Meter. By John K. Tuthill. Pp. 18. 20 cents. Reprint Series No. 50: Electro Organic Chemical Preparations, Part 4. By Sherlock Swann, Jr. Pp. 20. 20 cents. (Urbana, Ill.: University of Illinois, 1952.) [8

Jamaica. Annual Report of the Department of Agriculture for the Year ended 31st December 1951. Pp. 24. Department of Agriculture Bulletin No. 49 (New Series): Investigations, 1950–1951. Pp. 154. (Kingston: Government Printer, 1952.) [8

Department of Commerce and Industries: Division of Fisheries. Twenty-second Annual Report for the Year ended December 1950. By Dr. J. M. Marchand. Pp. 171. (Sea Point, S. Africa: Division of Fisheries, 1952.) [9

United States Department of Commerce: National Bureau of Standards. Circular 536: Radio-Frequency Power Measurements. By Ronald A. Schrack. Pp. iii+16. (Washington, D.C.: Government Printing Office, 1953.) 15 cents. [9

Sudan Government. Ministry of Agriculture: Forests Department Report for the Period January 1950 to June 1951. Pp. 62. (Khartoum: Ministry of Agriculture, 1952.) [9

## Catalogues

Reference Books and Bibliographies. (List 16.) Pp. 100. (New York: Herbert Reichner, 1953.)

'Speedivac' Physics Educational Equipment Models EQ1 and EQ2 (A.116/2.) Pp. 6. Vacuum Physics: 20 Fundamental Experiments using 'Speedivac' Educational Vacuum Equipment Models EQ1 and EQ2. Pp. 26. (London: W. Edwards and Co. (London), Ltd., 1953.)

Manuscripts, Early Printed and Woodcut Books, Old Science and Medicine. (Catalogue 20.) Pp. 68. (London: E. Weil, c/o National Provincial Bank, 9 Market Place, N.W.11, 1953.)

Gurr's Biological Stains and Reagents. (Price List B.) Pp. iv+3 (London: George T. Gurr, Ltd., 1953.)

# THE ROCKEFELLER FOUNDATION

THE Rockefeller Foundation was established in 1913; it was named after its founder, John D. Rockefeller, and although the Laura Spelman Rockefeller Memorial was combined with it in 1929, the original name was retained. Its purpose is quite simply "to promote the well-being of mankind throughout the world". An account of its activities has been prepared by Dr. Raymond B. Fosdick*, whose annual reports as president of the Foundation for more than a decade have become well known to scientific workers and others. Now he has written more particularly for the layman; he tells the story of the Foundation's achievements in the field of public health, starting with the control of hookworm, and broadening out to deal with malaria, typhus, tuberculosis and yellow fever, its contribution to medical education first in China and the United States and eventually over all the world, and the way these activities have led the Foundation to support a wide programme of medical research, and ultimately research in the social sciences and the natural sciences.

Quite apart from its value as a connected account of the development of the Rockefeller Foundation, the book could scarcely be bettered as an exposition of the contribution which science can make towards human welfare, and of the vital importance of adequate support for fundamental scientific research. These alone are sufficient reasons for welcoming the book at the present time; but there are others also why the volume is timely. The policy behind its fellowship programme of seeking solely to place the chosen Fellow in the institution where he could obtain the best possible training in the work for which he showed definite promise, no matter where the institution was located, provides a striking vindication of Mill's principle that "what the improvement of mankind and of all their works most imperatively demands is variety, not uniformity". The results of that policy refute the conception of uniformity or levelling down that finds expression, for example, in the comprehensive school. Moreover, the success of the fellowship programme, and the fruitfulness of even the limited movement of scholars across international frontiers which it has been able to foster, give plain warning of the dangers to mankind as well as to scientific advance inherent in all those tendencies which, especially during the past decade, have discouraged or prohibited scientific intercourse and the exchange of ideas.

Perhaps the main interest and chief importance of the book at the present time, at any rate, for scientific men, lie in the last two chapters. There Dr. Fosdick outlines the evolution of the principles and practices with which the Foundation now works, and finally attempts to estimate the place and significance of such a private—and voluntary—institution in the world to-day. Both chapters are as relevant to problems facing us in Britain as they are to the American scene which Dr. Fosdick possibly has first in mind.

---

* The Story of the Rockefeller Foundation. By Raymond B. Fosdick. Pp. 352. (London: Odhams Press, Ltd., 1952.) 25s. net.

Nor is it only to the administrator of research funds, either public or private, that the first of these chapters is of interest. Next to the importance of giving the public regularly sufficient information about a private foundation, or other voluntary body, so as to secure public confidence in, and understanding of, its purposes and work, Dr. Fosdick stresses the importance of elasticity. Enlarging on this and the undesirability of the grants of a foundation being tied up to rigid and unchangeable purposes, he shows that the trustees of the Foundation, following out Mr. Rockefeller's own ideas and distrust of the dead hand, have evolved a philosophy which avoids a danger, to which Lord Beveridge directed attention in his report on voluntary action and which Lord Nathan's committee is at present considering.

Dr. Fosdick describes the provisions regarding grants which the trustees have adopted to free the future so far as possible from frozen endowments. With this healthy scepticism of the ability of one generation to foresee the needs and requirements of the next, there goes much common sense that finds expression in other principles that have not always been given proper attention in the administration of grants. "Money", wrote Mr. Rockefeller nearly fifty years ago, "is a feeble offering without the study behind it which will make its expenditure effective"; and Dr. Fosdick emphasizes the dependence of any success in the Foundation's work on careful study and investigation as a basis for judgment. Once, however, grants are made to responsible groups or institutions, no degree of control over the operation of the grants has been or should be exercised by the Foundation.

Another danger to which Dr. Fosdick directs attention is the tendency to exalt the machinery of organization above the purpose for which the organization was created. The Foundation has indeed always placed much emphasis on the need for constant self-examination and adaptability to changing conditions. Departure from this principle, in fact, threatens the ability of the voluntary body to fulfil its prime and, as Lord Beveridge pointed out, indispensable function in the world of to-day—that of providing the growing-points of society, where there is freedom to experiment in ways that would not justify the commitment of public resources, or where such resources could not be deployed with the necessary freedom. The Rockefeller Foundation has, in fact, consistently recognized that its proper objective is to prime the pump, not to act as a permanent reservoir. With rare exceptions it has sought, in undertaking a new line of work, to begin in a small way and progress by trial and error to larger ends.

Manifestly the Rockefeller Foundation has been guided by essentially the same principles as the Nuffield Foundation and the Carnegie United Kingdom Trust, though its international preoccupations have rightly led the trustees to eschew some of the more local needs and problems that the other two bodies have been able to handle without risk of frittering away reserves on the trivial. The very success of such institutions in securing officers and trustees of the requisite quality, and the vindication of their policy of seeking first and foremost the most promising and most able men—of backing talent or brains, as Wickliffe Rose put it—contrasts sharply with some of the egalitarian tendencies of to-day. The question of the future of such foundations is inevitably raised by such a contrast, and all the more because the two main conclusions which Dr. Fosdick draws from his long experience strongly support the individualist point of view. The private foundation, writes Dr. Fosdick, should be a pioneering institution rather than a regular source of support for tried and established activities; it should work on the frontiers of knowledge and experience, rather than in the more settled areas behind. Moreover, promising men and creative ideas are the fundamentals; they are far more important than money, and the best that a foundation can hope to do is to put its support in the right place at the right time. Its utmost success lies in expediting the development of ideas which, without help, might be retarded.

The experience of the Rockefeller Foundation thus fully confirms that of the Nuffield Foundation and the Carnegie Trust, and endorses Lord Beveridge's argument as to the importance of voluntary action in the world of to-day if the opportunity for blazing new trails and for pioneering and creative experiments is to continue. Inevitably the question will be asked as to whether such bodies will be able or allowed to continue to function. Dr. Fosdick notes that, in its modern sense, the Foundation is an Americar phenomenon of the twentieth century. Only sever such foundations were established in the Uniteo States during the nineteenth century, wherea during the first decade of the twentieth a dozer new foundations were established, some twenty-twc in the second decade, and about ten a year sinc 1920.

Conditions in Great Britain are overweighte against the creation of any new trusts to-day, an recent reports point to the drying up of traditiona sources of income. The capacity of such bodies, a least in Britain, to continue operation in the ways i which they have been accustomed in the past, an on the principles which are so strikingly endorsed b Dr. Fosdick, is already seriously endangered; if the continue at all, their choice of objectives may be le adventurous and more difficult. Considerable as a the other merits of Dr. Fosdick's book, its greate service may well be its demonstration of the value the contribution which the voluntary body can mak to scientific advance and to social welfare in th world of to-day. It will remind us of the loss whic must follow if we fail to find effective measures f ensuring that opportunities and resources remain the disposal of the talented investigator or th creative minority to pursue their ideas untrammell by constraint of authority, orthodoxy or topic oth than their sense of duty to the community.

# TAXONOMY OF THE YEASTS

The Yeasts, a Taxonomic Study

By J. Lodder and N. J. W. Kreger-van Rij. Pp. xi+713. (Amsterdam: North Holland Publishing Company, 1952.) 130s.

THIS book, which is a successor to Stelling-Dekker's well-known "Die Sporogenen Hefen" (1931), to Lodder's "Die Anaskosporogenen Hefen I" (1934), and to Didden and Lodder's "Die Anaskosporogenen Hefen II" (1942), is based upon such a considerable intellectual effort and such an enormous amount of experimental work that it can truly be regarded as the 'Bible' of the yeast investigator. Few groups of organisms are so difficult to arrange into a reliable system of classification as the yeasts.

The authors have attempted in a most rational manner to overcome these difficulties, and, although this has necessitated considerable rearrangements in yeast taxonomy, compelling one to become accustomed to new names for previously well-established species, there is no doubt that their efforts, in general, have been successful. The basis for this study has been a thorough investigation of the extensive yeast collection of the Centraalbureau voor Schimmelcultures in Delft.

Morphological characters are employed in the book as the basis for the primary sub-divisions, and it is obvious that such characters, which may be observed without resorting to physiological tests, are of importance and are the most convenient and practical to employ. The yeasts as a whole are first divided into two large families and one small one—the ascosporogenous yeasts (Endomycetaceæ), the anascosporogenous yeasts which produce ballistospores on sterigmata (Sporobolomycetaceæ), and yeasts which produce neither ascospores nor ballistospores (Cryptococcaceæ). The further sub-division of these families into sub-families, genera and species is based upon morphological as well as physiological criteria. In all, approximately one hundred and eighty species and varieties are discussed. Whether the Sporobolomycetaceæ should actually have been included in this study is doubtful. This family, which comprises only a few species, all of which are unable to ferment, is treated in a special manner; in fact, the family name in the text does not appear as a page heading but has been replaced by "The Genera *Sporobolomyces* and *Bullera*".

It is not the place here to discuss the numerous examples of the grouping into a single species of forms which formerly were regarded as distinct species, nor to discuss the many instances of re-grouping within the genera. The authors have taken cognizance of the recent investigations showing that both *Zygosaccharomyces* and *Saccharomyces* diploidize in a similar manner and are therefore nearly indistinguishable, with the result that the only difference between them is that those types originally described as *Zygosaccharomyces* often remain haploid for a longer period of time than the others. With justification, the authors have placed all species of *Zygosaccharomyces* in the genus *Saccharomyces*.

The ability of each species described to ferment a series of sugars is listed, as well as the ability to assimilate the same sugars.

In Stelling-Dekker's book it is common to encounter species described under names which the author actually did not recognize. As an example, after the description of *Saccharomyces batatæ* Saito, it is stated that this form should be correctly classified under *S. cerevisiæ*. In Lodder and Kreger-van Rij's book, on the other hand, this yeast of Saito is discussed under the name which the authors accept: *S. cerevisiæ* var. *ellipsoideus*; this is obviously an improvement over the older work.

It is correctly stated on p. 45 that "two yeast strains which show the same sugar fermentation may not be genetically alike" and that the presence in a type of one or of several genes for the fermentation of a particular sugar "must inevitably be neglected in yeast taxonomy". The authors point out that the various constant morphological differences which are found must be considered to be of greater significance in classification.

The reliability of a taxonomic character such as pellicle formation, which is partly morphological and partly physiological, may be questioned. In the description of *Pichia* and of *Saccharomyces* on p. 54 and in the generic key on p. 78, the only significant difference between these two genera is the occurrence of pellicle formation in *Pichia* and its absence in *Saccharomyces*. However, we have found (through unpublished work performed by my former collaborator, O. Laustsen) that a *Hansenula* showing typical pellicle formation was able to segregate out from a single ascus two single-spore cultures with pellicle formation and two single-spore cultures without pellicle formation. All these four cultures were haploid. This fact indicates that pellicle formation is not a completely reliable systematic character. One may also question whether the generic character of *Hansenula* of nitrate assimilation is sufficiently important, in view of the fact that in many of the anascosporogenous yeasts both nitrate assimilating (N+) and non-nitrate assimilating (N−) species are found in the same genus.

It must be admitted that the difficulties encountered in erecting an acceptable system of yeast classification may justify the use of criteria which the systematist finds practical, even to the exclusion of a natural relationship and even if such a classification is not always completely logical. Of prime importance is whether the species can be identified by the system proposed, and in this respect the present work is certainly to be preferred to the earlier attempts.

It is inevitable that in such an extensive work errors will occur. With regard to minor errors, it can be noted that, on p. 333 as well as on other pages, "*Lypomyces*" is used instead of *Lipomyces*. In this connexion, it should be mentioned that, in the transfer of *Torula lipofera* to the genus *Lipomyces* (p. 335), the species should be called *Lipomyces lipofer* (not *lipoferus*, which is incorrect Latin). In the species index on p. 712 one finds "*Zygopichia*" as a heading for a long list of species. This should read "*Zygosaccharomyces*". It is incorrect to say that Lindegren (1949) "supposes that a dominant gene controls a high rate of enzyme production, whereas its recessive allele only is able to produce a very small amount of enzyme" (p. 46). This is the view held by Dr. Roberts and myself, proposed in 1948 in connexion with galactozymase, while Lindegren maintains that the recessive type, through mutation, may acquire the ability to synthesize the enzyme.

I am not in complete agreement with the statement that "If giant colonies are to be made the yeast is inoculated on malt gelatin in Petri dishes or Lindner flasks and observed after 4–8 weeks' incubation at 21° C.". I find that a lower temperature (15° C.)

produces a more characteristic surface appearance of the colonies, and that an incubation time of 3–4 weeks is quite sufficient. The authors have employed Einhorn tubes for their routine qualitative fermentation tests, although they consider Durham tubes more satisfactory. Actually, whether Einhorn or Durham tube is to be preferred depends upon the construction of the Einhorn. However, both tubes suffer the defect of allowing the carbon dioxide produced during fermentation to diffuse out of the sugar solution; this can, however, be overcome by employing mercury in the Einhorn. In our laboratory, we prefer the small Winge fermentometer, which is easy to use and inexpensive and which completely prevents gaseous diffusion.

These critical comments should, however, not detract from the merits of this imposing work, and there is good reason for congratulating the authors upon its completion. The book is provided with drawings which are a considerable improvement over those appearing in the earlier systematic works mentioned above. Nineteen new species and varieties have been erected and are described in Latin.

Øjvind Winge

# BRITISH PHARMACOPŒIA, 1953

### British Pharmacopœia 1953

Published under the direction of the General Medical Council. Official from 1 September 1953. Pp. xxiv+894. (London: Pharmaceutical Press, 1953.) 50s. net.

THE eighth "British Pharmacopœia", which becomes official on September 1, 1953, follows its predecessor after an interval of only five years. The Pharmacopœia Commission is to be congratulated on this acceleration of its output, which cuts down the time for this important standard work to get out of date. Much has happened during the past five years and many new drugs now appear for the first time, including aureomycin, cyanocobalamin, decamethonium, dibutylphthalate, ethyl*bis*coumacetate, folic acid, methadone, sodium aminosalicylate, troxidone and fifty-four other substances or preparations. There are also fifty-two new monographs which appeared in the addendum published in 1951 and now appear for the first time in the "Pharmacopœia" itself. The preparation of so much new matter is itself a formidable task; but the Commission has done much more than this. The number of old monographs ejected is even greater than the number of new monographs admitted. The Commission has shut its mind against sentiment and thrown out such old favourites as grey powder, Blaud's pill, squill, iodoform and aromatic spirit of ammonia. Some drugs, such as amidopyrin and diamorphine and sulphonal, are now thought too dangerous for general use, though some doctors still believe in them. Certain drugs of comparatively recent origin, such as acriflavine and dicoumarol and thiouracil, have been replaced by better drugs in the same class. The only remaining lozenge contains nothing but penicillin and sugar. As these examples will show, the Commission has spared no effort to ensure that the new book shall be efficient rather than picturesque and shall contain all essential drugs and nothing more.

The form of the book is more attractive than ever before. Latin has been deposed from pride of place, and the main title of each drug is given in English. The alphabetical arrangement has been improved, so that tincture of digitalis comes close to digitalis instead of being segregated with the other tinctures. Doses are given in the metric system, and the other weights and measures still used by old-fashioned doctors sometimes appear in brackets.

There is an interesting innovation in Appendix 15. Biological assays were first officially discussed in the 1932 "Pharmacopœia", and since then new methods of assay have been introduced from time to time, with various different recommendations for the design of the experiment. Some of the older ones were rather crude, and some of the newer ones were rather difficult to understand without much mathematical training. All such assays are based on the same general principles, and the Commission has prepared a section dealing with the design and accuracy of biological assays in general. It has thus been possible to eliminate repetition in the description of the separate assays and to introduce a simplified method of calculation which gives results accurate enough for all practical purposes. The methods now recommended are described in about a dozen pages with six examples of actual calculations, a table of *t*, a table of probits and a table of weights for probits. These methods of calculation do not include all the refinements recommended by some authorities, but they also do not include the inaccurate and unsatisfactory approximations recommended by other authorities; thus they should be found satisfactory for routine assays.

The new "Pharmacopœia", like all its predecessors, represents a great advance; but in this case the advance has been achieved in a very short time.

J. H. Gaddum

# SCIENCE IN PROGRESS

### Science in Progress

By Bradley M. Patten, George W. Corner, Arnold Gesell, H. J. Muller, T. M. Sonneborn, Ralph W. G. Wyckoff, Carl D. Anderson, Farrington Daniels, J. R. Dunning, Emil Artin, George Gaylord Simpson, Raymond M. Fuoss. Edited by George A. Baitsell. Seventh Series. Pp. xvii+512. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1951.) 40s. net.

THIS beautifully produced book is a worthy successor to the six former volumes in the series. Recent major contributions to many fields of science are described by the men who have been partly or wholly responsible for them. The new volume includes articles by two Nobel prize-winners and eight members of the United States National Academy of Sciences.

Dr. Bradley M. Patten writes of his research on the first heart-beats and the beginning of embryonic circulation in the developing chick; then follows a study of the action of ovarian hormones in the Rhesus monkey by Dr. George W. Corner, director of the Department of Embryology at the Carnegie Institution of Washington.

Dr. Arnold Gesell, who is known throughout the world for his work on the psychology of young children, presents a well-illustrated account of the psycho-physical development of the infant; analysis of cinema photographs of the child's reaction to its environment has been made possible by the use of a photographic dome for recording infant behaviour patterns. Then follows a long section by Dr. H. J Muller, of Indiana University, on radiation damage to the genetic material, in which much more research is called for on the long-term effects on tissue produced by frequent small doses of X-rays and other forms of radiation usually assumed to be safe.

The author of the next chapter, Prof. Tracy M. Sonneborn, professor of zoology in Indiana University, discovered a mating reaction associated with the conjugation of *Paramecium*, which culminated in the establishment of the concept of the plasmagene in cytoplasm, and he writes that "The ultimate task will be to reunite the nuclear and cytoplasmic components of the genetic system in an integrated, interreactional conception of the genetic system of the cell and the study of the function of each in the work of the whole". Dr. R. W. G. Wyckoff has a chapter on the structure of crystals, and his work is illustrated with some remarkable electron-microphotographs of virus crystals, in which the actual molecules may be seen. Carl D. Anderson, the discoverer of the positron, sums up the present position with regard to our knowledge of the elementary particles of physics, and Farrington Daniels, of the University of Wisconsin, reviews the possibilities of the future use of atomic and solar energy; no less than fifty fields of research in the utilization of the sun's energy are listed.

Pure mathematics has been given consideration in a section by Emil Artin, of Princeton University, in which the theory of braids is worked out by combining topology and the theory of groups. Finally, there are important chapters on the fauna of Latin America by George Gaylord Simpson, and on the physical chemistry of polymers by Raymond M. Fuoss. Each chapter is well documented.

W. L. SUMNER

# PROGRESS IN THE STUDY OF REAL CRYSTALS

Institut International de Physique Solvay
Neuvième Conseil de Physique tenu à l'Université Libre de Bruxelles, du 25 au 29 septembre 1951. L'État solide: Rapports et discussions. Pp. 577. (Bruxelles: R. Stoops, 1952.) 650 francs.

THE scientific committee of the Institut International de Physique Solvay convenes periodically a conference at which problems of some branch of physics are reviewed. The reader learns from the table of contents or from an aside on p. 167 that the main theme of this conference report on the solid state is that of imperfections and transformations, and principally the former. The book is a collection of papers, with discussions, and the majority deal specifically with studies of metals, although most problems treated have a wider application. Some of the papers review an aspect generally, but most describe particular developments with which the authors have been personally associated. Much of the subject-matter has, of course, been published already, and indeed, as is perhaps inevitable in a field in which such rapid developments are occurring, has also been discussed at recent conferences of similar scope. There is, however, some new work of interest to the specialist, and although its nature makes it rather disjointed, the book is to be recommended to a wider circle as an authoritative account of the state of development at September 1951 of he topics discussed.

The book begins with a fascinating paper by C. S. Smith describing the recent work on grain boundaries which has been stimulated by comparing the polycrystalline solid with a soap froth. There are three other papers concerned directly with grain boundaries and their properties. W. G. Burgers, discussing recrystallization, gives a comprehensive review of new data and ideas which have appeared since 1940 and includes a survey of new techniques for studying structural changes. G. W. Rathenau describes the application of one of these—electron emission microscopy—to the direct study of grain-boundary migration in metals at high temperatures. Calculations on the energy of grain boundaries using the dislocation model are reported by W. Shockley.

There are five papers about transformations. E. Rudberg reviews recent Swedish work, and this is supplemented later by a brief note from G. Borelius. Age-hardening and the order–disorder transformation are treated by W. Köster and A. Guinier, while C. Crussard describes his theory of the interference of thermal waves and its applications. Lattice vibrations are also discussed in J. Laval's detailed account of his theoretical work on the elastic properties of a perfect crystal in which the interatomic forces are not central.

The remaining papers are all concerned directly with the theory of dislocations. E. Orowan discusses the dynamics of slip and examines critically some of the fundamental hypotheses of this theory. There are articles by F. C. Frank on crystal growth, F. Seitz on the generation of vacancies by moving dislocations, and A. H. Cottrell on the yield-point in iron. N. F. Mott discusses current ideas on work-hardening, recovery and creep, and there is a short note from U. Dehlinger.

The dislocation theory has made great strides since the Second World War. At the time of the Bristol Conference in 1947, perhaps the most convincing parts of the theory were the explanations it afforded of the influence of traces of impurity on mechanical properties (atmosphere theory), and of the phenomenon of polygonization. Since that time the observation of spiral steps on the surfaces of growing crystals has provided direct evidence for the existence of dislocations. Also, the actual propagation of slip lines across the surface of a specimen has been studied with the high-speed camera. At the same time, it is now possible to understand how slow-moving dislocations can multiply. Already, important new evidence of the co-operative movement of dislocation arrays, predicted and referred to briefly in the paper of W. Shockley at this conference, is available in the experiments of Washburn and Parker, while the comparison of absolute grain-boundary energies for small angular disorientations with the predictions of the dislocation theory appears to make possible the first quantitative test of this theory. Much of the theory remains, however, frankly speculative, and, as E. Orowan emphasizes, the need for experimental support for its foundations is acute. There is some ground for confidence, however, that this will be increasingly forthcoming in the near future.

Despite its title, English-speaking readers will be glad to know that some three-quarters of the book is in their language. It is perhaps unkind to comment on the numerous errors of editing which result; but it is impossible to refrain from quoting the apposite heading of "Creed and Polygonisation".

B. A. BILBY

### Classical Mechanics

By Dr. D. E. Rutherford. (University Mathematical Texts.) Pp. viii+200. (Edinburgh and London: Oliver and Boyd, Ltd.; New York: Interscience Publishers, Inc., 1951.) 10*s*. 6*d*. net.

DR. D. E. RUTHERFORD'S aim is to provide a concise and unified account of classical theoretical mechanics from the beginning up to Hamilton's principle. There are five chapters, dealing respectively with kinematics, the nature of force, dynamics of a particle, dynamics of rigid bodies and generalized co-ordinates. A surprisingly large amount of information has been packed into a small space. For example, Chapter 4 contains not only the usual elementary theorems on rigid dynamics, and an account of Euler's equations and the top, but also some statics, including centre of gravity, Poinsot's central axis and virtual work. Chapter 5 includes Lagrange's equations, normal modes of oscillation, stability, Hamilton's equations and Hamilton's principle. There are examples for solution at the end of each chapter, the total number being 108, and an index.

There can be no doubt as to the value of the matter contained in the book; but it is rather puzzling to know for what type of student it is intended. The introduction points out that a knowledge of calculus, co-ordinate geometry, and vectors is required. It does not mention that p. 141 uses the notation and two theorems of matrix theory. Also there is no statement as to the previous knowledge of dynamics required; but it is obvious that a beginner will find great difficulty with some of the early pages—for example, p. 13 on moving axes. The introduction stresses that the book is arranged in logical order and not in order of increasing difficulty, and that "many readers may find it advisable, therefore, to read the various sections in an order other than that in which they are presented. Teachers will, no doubt, advise their students on this point according to the students' maturity". This last sentence transfers the task of presenting the subject in a form that can be easily assimilated from the author's to other shoulders.

H. T. H. PIAGGIO

### The Cold Working of Non-Ferrous Metals and Alloys

A Symposium on Metallurgical Aspects of the subject held in London on the occasion of the Annual General Meeting of the Institute, 14 March 1951. (Institute of Metals Monograph and Report Series, No. 12.) Pp. 207. (London: Institute of Metals, 1952.) 15*s*.

THE five papers which make up this symposium are reviews of particular aspects of cold-working, such as wire-drawing, cold-rolling and pressing. The practical techniques employed are examined in relation to the optimum process conditions for the more commonly used non-ferrous metals and alloys, with the fundamental aspects of cold-working reviewed in one general introductory paper. This may represent a just proportion in a work on applied metallurgy, but even in this paper the discussion is not extended to cover any detailed theory. The interpretation of cold-working phenomena in terms of dislocations, and the treatment given of deformation textures, are both so generalized that they give no more than a brief indication of current ideas. This is unavoidable in the space of the few pages devoted to these subjects, and the selection of the material, which must have been a difficult task, is, on the whole, well judged. The volume is clearly a most useful work for those actively connected with industrial processes which involve cold-working in any form. Most problems are touched upon, and where detail is inadequate the quoted references may be followed up. However, as the development and extension of such techniques depend upon a fuller understanding of the metallurgy and physics of the deformation mechanisms, a closer consideration of fundamentals would have widened its appeal.

A. J. KENNEDY

### Entwicklungsphysiologie

Von L. v. Ubisch. Pp. 85+16 plates. (Berlin: F. W. Peters, 1952.) n.p.

PROF. VON UBISCH has made important contributions to the experimental embryology of a wide variety of forms—echinoderms, ascidians, *Ascaris* and amphibians among them. He has, however, stood somewhat outside the major schools, such as the German, the Swedish and the Belgian, which have tended to dominate the subject in the past few decades, and his contributions have perhaps received rather less attention than was their due. It is therefore all the more gratifying to have from his pen a general treatment of the field. His little book is exceedingly short and is aimed at a student audience. Its brevity has enforced a most admirable clarity of theoretical outlook. Von Ubisch presents a very modern point of view: that the essential basis of differentiation is to be sought in the interaction between nuclei and locally differentiated cytoplasms, by which different sets of genes become activated or inhibited. In the space at his disposal the author can do little more than adumbrate this proposition and has had to forgo a discussion of much of the widely diversified evidence which bears on it, particularly from the side of genetics. However, little of major importance is omitted from his summary of the facts of experimental embryology, and his book is probably the best short and up-to-date account of it.

C. H. WADDINGTON

### Leibniz und das Reich der Gnade

Von Kurt Hildebrandt. Pp. viii+505. (Haag: Martinus Nijhoff, 1953.) 26.50 guilders.

CONTEMPORARY scholarship may perhaps be said to have 're-discovered' Leibniz; the stately volume here under review is not the only evidence of this trend in recent months, but it is a contribution of a somewhat special character, designed to set the great thinker at the centre of a specifically European philosophy, occidental in spirit and intended to be "understanded of the people". To this extent, it represents a return to the early Greek concept, when the love of wisdom was taught not so much as an academic subject, as a life to be lived. Thus, a not inappropriate rendering of the title of the present work might be "Leibniz and the Realm of Grace".

The first part is largely biographical, including the encounters with Locke and Newton. Next follows a typical *Systematik*, an assessment of the creative faculty in mankind, and the problem of good and evil. (The celebrated "Theodicy" comes in for attention earlier.) Finally, there is the inevitable discussion of action and re-action, including questions of belief and configuration. The latter should not be confused with the *Gestalt* of to-day; for Leibniz, 'shape' was more of an abstraction than it is to us. The book—a work of real distinction—concludes with a useful chronological table.

F. I. G. RAWLINS

## An Explaining and Pronouncing Dictionary of Scientific and Technical Words

10,000 Scientific and Technical Words in 50 Subjects explained as to a Person who has little or no Knowledge of the particular Subject. By Dr. W. E. Flood and Dr. Michael West. Pp. viii+397. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1952.) 12*s.* 6*d.* net.

THIS is a very useful compact dictionary, and it will have a wide acceptance. In less than four hundred pages, ten thousand scientific and technical words in fifty subjects ranging from architecture to zoology are explained and given correct pronunciations. Like Larousse and Nuttall before them, but in a more generous and enlightened manner, the authors have supplied thirteen hundred pictures and diagrams to assist them in their explanations. A simple and effective method of cross-reference has been used in the book, and thus its value has been enhanced. The authors set themselves a number of working rules when they made their dictionary, and, by following these, their work has not degenerated into an unsatisfactory encyclopædia. Only a captious critic would find details which would evoke comment.

Why has oxygen not been given when nitrogen and hydrogen have? Why axolotl and not salamander, geriatrics and rheology but not cybernetics, harmonic but not consonance or temperament in their acoustic sense, coma with two meanings but without reference to lens aberrations? There is tawny port wine (which is important), but not polyploid, serology or the biological use of the word spindle. Very few of the explanations have suffered through the process of condensation, but some seem to need qualification; for example, "calciferol is found in yeast", "burn bones to make lime". There is a table which gives British and metric weights, measurements and temperatures, but atomic weights are not usually given. The most hypercritical reviewer would have to admit that in such a small but comprehensive volume some matters of choice must be left with the authors.

The book is excellent value for money and is attractively produced. It will be handy as a reference work for all intelligent citizens, even if their primary interest is not science. Many will be tempted to browse in it.
W. L. Sumner

## Tables of the Bessel Functions of the First Kind of Orders Seventy-nine through One Hundred and Thirty-five

By the Staff of the Computation Laboratory. (Annals of the Computation Laboratory of Harvard University, Vol. 14.) Pp. x+614. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1951.) 52*s.* net.

THE publication of this volume completes a project inaugurated in 1944 by the Computation Laboratory of Harvard University and continued since, at intervals, whenever the Laboratory's automatic computer was not engaged on work of higher priority. The results are given in a series of large volumes, of which this is the twelfth. Previous volumes in the series have been reviewed (*Nature*, 160, 772 (1947) and 163, 152 (1949)), and there is not much to add to what has already been said.

The original project was to tabulate the function $J_n(x)$, for positive integer $n$ up to 100 and for values of $x$ up to 100, to ten decimals, except that, for $n = 0(1)3$, values are given to eighteen decimals. For $x$ greater than 25, the tabular interval has so far been 0·01, but in the present volume it is increased to 0·05 at $n = 97$, and again to 0·1 at $n = 112$. It has been found possible to increase the range of $n$ up to 135, beyond which $J_n(x)$ is not significant to the tenth decimal at $x = 100$. The range of $x$ has been closed by the inclusion of a ten-decimal table of $J_n(100)$ up to $n = 135$, and a table of $J_n(n)$ for $n = 1(1)100$ is also given.

Dr. H. Aiken and his staff—and also the machine—are to be congratulated upon the completion of the great task which they set themselves, and the result is probably the most extensive piece of tabulation which has so far been attempted and brought to a successful conclusion.
W. G. Bickley

## Du Pont

The Autobiography of an American Enterprise. The Story of E. I. Du Pont de Nemours and Company published in commemoration of the 150th Anniversary of the Founding of the Company on July 19, 1802. Pp. vi+138. (New York: Charles Scribner's Sons, 1952.) n.p.

THIS handsome volume, richly illustrated partly in colour, traces the development of a famous American firm from its foundation in 1802 near Wilmington, Delaware, by a young refugee from France, Eleuthère Irénée du Pont, who had been a pupil of Lavoisier. Many of the illustrations connected with the early period are taken from the contemporary press and are of great interest in respect of such things as costume. The illustrations showing present-day conditions may seem at first sight too familiar to warrant inclusion; but in due time they also will come to be records of past days, equally interesting and valuable. The volume, which has drawn upon many sources, including the records of the firm, is one of the most interesting and attractive of its type which has come to the notice of the reviewer, and any library which looks to the future should make a point of including it.

## The Bay

By Gilbert C. Klingel. Pp. x+278. (London: Victor Gollancz, Ltd., 1952.) 12*s.* 6*d.* net.

THE bay of which Gilbert Klingel writes is the Chesapeake, stretching to the east of Maryland and Virginia, and so called after the American Indians who first peopled its shores. The coast is deeply indented with wide river mouths, long lagoons, estuaries, and thousands of small creeks, so that, it has been said, if the shore-line were straightened out it would stretch more than four thousand miles. For twenty years Klingel has watched the bay with the acute perceptions of an enthusiastic and experienced naturalist. In this book he describes the bay in many moods as well as the remarkable variety of its living forms. The latter he has studied above, on and below the surface of the bay; possibly his best descriptions are those of the living creatures which he met underwater. For Klingel is an experienced underwater observer and, whether in helmet, diving-suit or his curious home-made 'Bentharium', his close contacts with submarine life have produced descriptions of animal behaviour which put him in the top flight of writers on natural history. One of the best chapters is an account of happenings during a whole twenty-four hours spent in the heart of a swamp. The chapter on luminescence is equally good, while the author's description of his experience with the 'Bentharium' is one of exciting adventure.

# THE SUPERSONIC BANG

By G. M. LILLEY, R. WESTLEY, A. H. YATES and J. R. BUSING
Department of Aerodynamics, College of Aeronautics, Cranfield, Bucks

THE reason for the bang or bangs heard by ground observers after an aircraft has exceeded the speed of sound has been the subject of much speculation. In previous communications, Gold[1], Warren[2] and Rothwell[3] have based their explanations on Huygens's wavelet construction for a moving source which replaces the aircraft. They have shown that an observer will experience a bang if $-dr/dt = c$, where $r$ is the (scalar) distance between aircraft and observer, and $c$ is the speed of sound. This is simply the condition for the pulse waves emanating from successive elements of the supersonic flight path to form an envelope or wave front (Mach wave).

For a source moving in a straight line at a speed which increases and then decreases through the speed of sound, two curved wave fronts are formed, joined at their outer extremity by cusps (see Figs. 1–4 inclusive).

In the simple theory it is assumed that these waves, which eventually move ahead of the retarded source, cause bangs as they pass the observer. Although the calculated time interval between the two bangs, and the strength of the first wave front, have shown reasonable agreement with measured values obtained from a restricted series of flight experiments, the calculations to date do not predict a second wave front of comparable strength to the first. Experiments with aircraft in dives have shown, however, that the strength of each component of the double-bang is approximately equal. If instead of the Mach wave configuration the shock waves around an aircraft, in unsteady as well as steady flight, are considered, this discrepancy between theory and experiment does not arise.

Since it is only necessary to discuss the pattern of the shock wave at large distances from the aircraft, it is possible to replace the aircraft by an equivalent body of revolution. This avoids the complicated

treatment of the multi-shock interaction close to the aircraft. Simple experiments[4] based on the hydraulic analogy technique, using towed models, have verified the shock-wave explanation of supersonic bangs (see Figs. 5–8).

## Shock-wave Configuration in Unsteady Flight

When a body is uniformly accelerated from rest up to high subsonic speeds below the critical Mach number (the Mach number of the body at which the local speed near the surface first reaches sonic speed), the flow pattern around the body at each instant will not be markedly different from that at the corresponding steady speed. At flight speeds above the critical Mach number, shock waves are formed around the body at the end of the local supersonic region. These shock waves move back towards the tail as the Mach number of the body is increased. At a sufficiently high subsonic Mach number, the tail shock becomes bifurcated with its rear member nearly normal to the wake (Fig. 5).

When the acceleration of the body is continued to supersonic speeds, a bow wave is formed just ahead of the body (Fig. 6). Unlike the front tail wave, it remains approximately normal, near the body, at least over a finite range of supersonic speeds. It becomes attached to the nose, if sharp, above a certain supersonic Mach number, which is a function of the nose angle (Fig. 7). The extent of the bow wave and its distance from the nose is a function of the body geometry, the body speed and acceleration, as well as the complete time-history of the motion. Thus the bow wave can only attain its steady state configuration after an infinite time. Away from the body axis the interaction of the expansion waves (which are necessary to accelerate the flow between the bow and tail waves) with the bow wave reduces its inclination relative to the flight path. It can be seen, therefore, that marked differences occur between the formation of the bow and tail waves. In the latter case, the wave is concave forwards, close to the body (Fig. 5), and the formation of its rear member is therefore analogous to that of the Mach waves associated with an accelerated point source (Fig. 3). The bow wave is, however, convex forwards (Fig. 6), and a simple qualitative analysis will show that the flow inhibits the formation of cusps at its outer extremity. Thus for a body accelerated from subsonic to supersonic speeds, the shock formation consists of a bow wave ahead of, or attached to, the nose, and separated from the front tail wave by a system of expansion waves, plus a rear transverse wave joined to the front tail wave at its outer extremity.

When the body is retarded and its speed falls below the critical Mach number, the bow wave will have travelled far ahead of the nose, since it detaches itself from the body when its speed is just above sonic. The front tail wave will travel slowly towards the nose, and in doing so becomes approximately normal to the surface. Its shape changes and it becomes convex to the direction of the motion. It moves ahead of the body when the speed of the latter falls below the critical Mach number. The rear tail wave moves towards the body, overtakes it, and finally it also moves ahead of the body (Fig. 8). Thus the shock wave formation ahead of a body, retarded from supersonic motion of finite duration to subsonic, is a bow wave separated from the front tail wave by a system of expansion waves, and trailing farther behind a rear transverse wave joined to the front tail wave at its outer extremity. The two members of the tail wave tend to coalesce after a finite time. Thus at a large distance ahead of a body executing this simple manœuvre, we shall have either two or three shock waves each travelling at approximately the speed of sound. The first two waves will have similar strengths, whereas the third wave, if it has not overtaken the front tail wave, will be considerably weaker.

The distance apart of the shock waves can be calculated approximately as follows. The distance between the bow and the front tail wave is equal to the speed of sound multiplied by the time for the body to slow down from sonic speed to just below its critical Mach number. The distance between the bow wave and the rear tail wave depends on the time-history of the accelerated and then retarded motion of the body. When this is known, the calculation can be completed, since it has been shown that the rear tail wave is left behind in the wake of the body at the commencement of the supersonic motion, while the bow wave separates from the body at the conclusion of the supersonic motion. In addition, as a first approximation, it may be assumed that the free shock waves are moving normal to themselves at the speed of sound. The spread of the shock waves after a given time can be found approximately from the corresponding Huygens wave diagrams for the motion of a point source which replaces the body.

In the case of steady motion at supersonic speeds, the bow and tail shock waves are of infinite extent, except where they are reflected from solid surfaces. The rear tail wave is now infinitely far behind the body and hence is not observed.

### Noise from High-speed Aircraft

In the case of jet-propelled aircraft travelling at high subsonic speeds, the main noise is due to the turbulent motion created by the jet. At supersonic body speeds, the sensation of noise caused by shock waves, even when they are weak, is very much greater than that due to other sources, although the duration of the noise is very short. For a body flying at constant supersonic speed at a fixed altitude, the bow and tail shock waves will sweep over the ground, and these and their reflexions will be heard by observers as separate bangs, only if their time interval is greater than about 0·02 sec. For a body executing a high-speed dive, during which the speed increases and then decreases through sonic speed, ground observers may hear one, two or three bangs depending upon their location and the time-history of the motion. In the cases where more complicated manœuvres are executed, simple analysis will determine the number of bangs to be expected.

In the discussion above, the refraction of the shock waves through a non-uniform atmosphere has not been considered. This will not invalidate the above results; but it should be noted that for certain manœuvres the shock waves produced around the body at altitude will not penetrate to the ground.

## HEALTH OF THE SCHOOL CHILD[*]

THE report of the Chief Medical Officer of the Ministry of Education for the years 1950 and 1951 shows that the mortality-rate of children aged 5–14 years is still falling. Of the 3,341 children who died in 1950, 851 met their deaths through accidents—about half of them motor accidents. 294 children died of tuberculosis compared with 937 in 1938, 207 of cancer and 153 of poliomyelitis. Deaths from diphtheria continued to fall: 16 children died in 1950 compared with 1,733 in 1938. The general health of the children continues to improve.

There has been a remarkable reduction in skin disease among children. During 1947–51 the number of children with scabies, impetigo and ringworm of scalp has fallen from 108,000 to 34,000. Acute rheumatism is being reduced, and although more than 4,000 children a year suffer from this disease, this is less than a third of the number ten years ago.

Cleanliness of school children is also improving. "Even so," states the report, "it is inexcusable that 347,544 children (6%) were found verminous in 1951. Parents of consistently verminous children must have very little self-respect." A persistent campaign is being waged against this problem; but success in preventing repeated re-infestation depends upon the measures taken to deal with possible verminous conditions in other members of the family—in particular, the pre-school child and the young adult. In one area, methods of treatment include an offer of DDT hair-cream to the parent.

Nearly 4¼ million children were examined or re-examined during 1951 by school medical officers. 157,566 children were found to have defects in vision and a further 37,499 children required treatment for squint compared with 31,189 in 1949. Nearly three children in every thousand required treatment for defective hearing, and nearly five in every thousand were recommended to be kept under observation. More attention is now being paid to the ascertainment of deafness in children as it is considered vital to treat them early in school-life.

The report includes a highly critical survey of open-air schools by four medical officers of the Ministry. In their account of premises they state: "There are in this country some first class open-air schools which have been designed to give the children full benefit from fresh-air and sunlight, but there are others which are merely ramshackle wooden huts, unpleasant to live in and ugly to look at. In some of the schools the walls were simply screens, made partly of wood and partly of canvas extending from the floor about 2–4 feet from the ceiling. The rooms were without any means of heating and were often without artificial light. In wet, windy weather, rain drove in between and above the curtains so that the floor and furniture were often wet. We saw children scraping frozen snow off the desks and chairs before they could be used. In cold weather the children sat at their desks wearing hats, caps, coats, scarves and gloves, and with blankets round their legs. As doctors, we cannot feel that refrigeration or dampness contributes to health and, therefore, we strongly condemn the 'bandstand' type of classroom. In one school on a wet day we saw the children lying on damp canvas stretchers in an unheated, open-fronted stone-floored shed, with the rain driving in at the front and leaking through the roof".

The report explains that a well-conducted open-air school is of great value for delicate children, and apart from its physical benefits, they usually find sheer pleasure in being out of doors; but they must be kept dry and reasonably warm. There is still a place for these schools, especially in industrial areas; but no expansion of existing provision is considered necessary. "With a rising standard of living, better housing, the provision of meals and milk in schools, and with a fuller appreciation in the ordinary schools of the varying needs of individual children, it may be that the need for special schools for 'delicate' children will diminish with the years."

# BIOSYNTHESIS OF PROTEINS*

By Dr. P. N. CAMPBELL and Dr. T. S. WORK
National Institute for Medical Research, Mill Hill, London, N.W.7

BIOCHEMICAL research has been concentrated until recently on the degradative rather than on the synthetic reactions of the living cell. This was the natural outcome of limitations imposed by technique. The products of degradation are small molecules amenable to investigation by the classical techniques of organic chemistry, whereas the products of synthesis are often of high molecular weight and of embarrassing complexity. The introduction of isotopic tracers, of chromatography and of high-speed centrifuges has made possible a reorientation of research. Among the many problems open to attack by these new methods, that of protein synthesis is among the most formidable and most important.

Proteins such as those of hair and skin cannot be said to have any definite molecular weight and they may well have no definite molecular structure, but the smaller water-soluble proteins when purified show many of the attributes of homogeneous molecular species. Thus, for example, it seems likely that all the insulin molecules produced by one animal are of identical structure. There is no indubitable proof of this view, but the recent determinations by Sanger and Porter[1] of protein end-groups, the work of Porter[2] and of Schroeder[3] on amino-acid sequences adjacent to the end-groups, and especially the recent work of Sanger[4] on the amino-acid sequences in insulin, all suggest that a single purified protein is a single molecular species.

It is known from the classical investigations of Nuttall[5] and others that the morphological differences between species are no more distinct than the serological differences between the proteins of those species. Thus, for example, purified duck ovalbumin can be distinguished from purified hen ovalbumin by immunological methods[6]. In the same way the serum globulins, the fibrinogens, the trypsins and the hæmoglobins of two closely related species may be indistinguishable by physical methods but serologically distinct. The work of Landsteiner[7] and others has suggested that immunological specificity is the reflexion of a specific chemical structure. Thus it is reasonable to suppose that each type of cell possesses enzymic mechanisms capable of exact control of the amino-acid composition and sequence of all its proteins. This conclusion is fortified by the recent investigations of Sanger[8], of Lens[9] and of Craig[10] on sheep, pig and bovine insulins. These proteins are indistinguishable by physical methods and are of equal biological potency but are chemically distinct. Apparently the pancreatic cells of each species control the exact reproduction of a complex polypeptide pattern characteristic of the species. For some proteins the specificity of structure appears to be controlled within even narrower limits than that of the species and is characteristic of the family, the specific immunological character of the protein then being inherited within the family. To understand the mechanism of protein synthesis is thus a step towards understanding the inheritance of character and the continuity of the species.

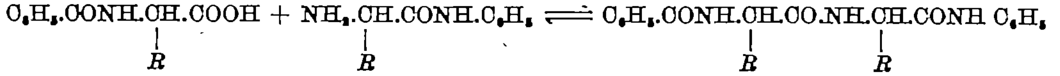
## Protein Turnover in the Adult Animal

In the early years of the present century much progress was made in the study of protein digestion. By 1920 it was generally accepted that ingested protein was degraded by proteolytic enzymes in the stomach and gut and that the nitrogen was absorbed as free amino-acids[11]. The work of Folin[12] indicated that in the adult the dietary amino-acids were rapidly oxidized, and thus most of the nitrogen was excreted as urea. It was assumed, therefore, that protein synthesis almost stopped when growth stopped. However, in 1935 Borsook and Keighley[13] presented evidence to suggest that there is a continuous and high rate of protein synthesis even in the adult animal. In 1939 this conclusion was supported by the results of Schoenheimer[14] on the distribution of isotopic nitrogen ($^{15}N$) after feeding $^{15}N$-glycine to rats. This work proved beyond doubt that there is, even in the adult animal, a constant and rapid turnover of many body proteins. Shemin and Rittenberg[15] later showed that the average life of rat liver protein was about seven days. Such rapid turnover is not, however, characteristic of all body proteins, since Neuberger and Slack[16] have recently shown that the rate of turnover of collagen in the adult rat is very low.

## Enzymic Synthesis of Protein *in vitro*

When proteolytic enzymes are allowed to act upon protein in dilute aqueous solution, there is rapid hydrolysis of peptide bonds and liberation of small peptides and amino-acids. However, so long ago as 1901, Sawjalow[17] showed that when a concentrated solution of peptone was treated with fresh gastric enzyme there was formation of a precipitate which appeared to be protein in nature. This material was given the name 'plastein'. Even to-day, plastein formation continues to excite considerable interest as the simplest example of protein synthesis (cf. Tauber[18]).

The work of Bergmann and his colleagues, especially Fruton, on synthesis of small peptides by proteolytic enzymes has done much to clarify the mechanism of plastein formation. It is fundamental to the definition of an enzyme that it should be able to catalyse a reaction in both directions. For example, in dilute aqueous solution papain catalyses the hydrolysis of casein; but if papain is incubated with a concentrated solution of benzoylleucine and leucine anilide, a peptide bond is formed between the two leucines and benzoylleucylleucine anilide is precipitated from the solution:



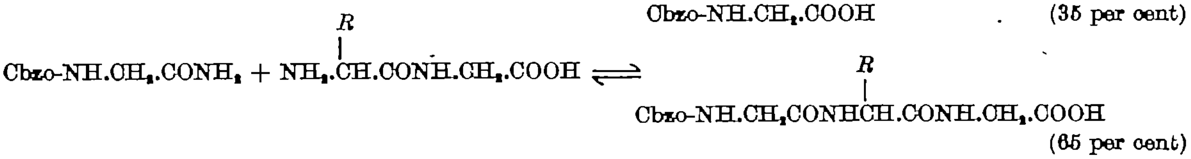
$$C_6H_5.CONH.\underset{R}{\underset{|}{CH}}.COOH + NH_2.\underset{R}{\underset{|}{CH}}.CONH.C_6H_5 \rightleftharpoons C_6H_5.CONH.\underset{R}{\underset{|}{CH}}.CO.NH.\underset{R}{\underset{|}{CH}}.CONH\,C_6H_5$$

Benzoylleucine and leucine anilide are readily soluble in water, but benzoylleucylleucine anilide is very sparingly soluble. Papain catalyses the reaction in both directions, but the very low solubility of benzoylleucylleucine anilide in water causes immediate precipitation of the peptide as formed and the reaction is forced from left to right (Bergmann and Fraenkel-Conrat[19]).

---

* Based on two lectures given by Dr. T. S. Work, honorary lecturer in pharmacology, at University College, London, on February 16 and 20.

During the past three years, Fruton[20] has shown that proteolytic enzymes also catalyse the exchange of one amino-acid for another within a peptide chain. Papain was incubated with carbobenzoxyglycine amide, leucylglycine and buffer. The enzyme catalysed the hydrolysis of the amide link in carbobenzoxyglycine amide, but not that of leucylglycine. When the reaction mixture was analysed it was found to contain 35 per cent carbobenzoxyglycine and 65 per cent carbobenzoxyglycylleucylglycine :



$$\text{Cbzo-NH.CH}_2\text{.CONH}_2 + \text{NH}_2.\overset{\overset{\textstyle R}{|}}{\text{C}}\text{H.CONH.CH}_2\text{.COOH} \rightleftharpoons \begin{array}{ll} \text{Cbzo-NH.CH}_2\text{.COOH} & \text{(35 per cent)} \\ \text{Cbzo-NH.CH}_2\text{CONH}\overset{\overset{\textstyle R}{|}}{\text{C}}\text{H.CONH.CH}_2\text{.COOH} & \text{(65 per cent)} \end{array}$$

The enzyme had thus catalysed not only hydrolysis but also exchange of a peptide for a simple amide nitrogen. This transpeptidation, as it has been called by Fruton[21], shows that a proteolytic enzyme such as papain can act to lengthen a peptide chain provided that the necessary energy is available in the form of a preformed amide or peptide bond.

It is now reasonably clear that in plastein formation the concentrated solution of low-molecular weight peptides undergoes partial hydrolysis and partial transpeptidation, so that during the rather random rearrangement which takes place some peptide chains grow at the expense of others and eventually are precipitated as protein-like material.

## Transpeptidation as a Mechanism for Protein Synthesis

It is known that all cells contain intracellular cathepsins, which are enzymes similar to papain, and it may reasonably be asked whether such enzymes could be responsible in part for protein synthesis. From our knowledge of the behaviour of proteases *in vitro* and from a knowledge of the thermodynamics of peptide-bond formation, it is possible to say at once that, if the intracellular cathepsins do take part in protein synthesis, they could only do so when provided with a supply of energy, probably in the form of a pool of preformed amide or peptide bonds. Study of amide-bond formation was initiated by the observation of Fuller[22] that sulphanilamide given by mouth is rapidly acetylated and excreted in the urine as acetylsulphanilamide. In 1945 Lipmann[23] found that a homogenate of pigeon liver could acetylate considerable quantities of sulphanilamide under aerobic conditions, but that anaerobically acetylation was slight unless adenosine triphosphate was added to the homogenate. In Lipmann's nomenclature, this suggested that energy for amide-bond formation was supplied by the energy-rich phosphate bonds of adenosine triphosphate. Borsook and Dubnoff[24] showed that adenosine triphosphate also stimulated formation of hippuric acid by guinea pig liver homogenates. Moreover, the formation of glutamine from glutamic acid by cell-free enzyme preparations was shown by Speck[25] and by Elliott[26] to require adenosine triphosphate. True peptide-bond formation as opposed to simple amide-bond formation has been studied by Bloch[27]. An extract was obtained from pigeon liver which catalysed the formation of glutathione from glutamylcysteine and glycine. For this condensation a supply of adenosine triphosphate was essential.

The exact mechanisms of these examples of amide- and peptide-bond formation are not understood, but it is clear that cells possess a variety of mechanisms for the conversion of phosphate-bond energy into amide or peptide bonds. Thus, from the thermodynamic point of view, there is no insuperable objection to supposing that protein synthesis takes place by transpeptidation catalysed by the intracellular cathepsins.

Attempts have been made during the past few years to obtain direct evidence for the conversion of simple amides and peptides into other peptides by transpeptidation. Waelsch[28] has shown that cell extracts can catalyse a reaction between glutamine and various amino-acids to give γ-glutamyl peptides. Hanes, Hird and Isherwood[29] have shown that kidney extracts catalyse formation of γ-glutamyl peptides from glutathione and various free amino-acids. In each case the product is a γ-peptide and not an α-peptide, and therefore the reactions are not quite satisfactory as examples of cellular transpeptidation from an amide-bond pool; but further work along the same lines may well reveal other examples of transpeptidation or other amide-bond pools.

## Objections to the Transpeptidation Theory

It should be clear from what has been said that there is much indirect evidence in favour of transpeptidation as a possible mechanism for protein synthesis. Evidence that a theory is possible should not be taken as proof that it is correct; there are various observations difficult to reconcile with a transpeptidation mechanism.

It is obvious that, if protein synthesis takes place by transpeptidation, there should be present in cells a great variety of intermediate peptides, and we should expect that cells would find no difficulty in using for synthesis peptides supplied in their nutrient medium. Many experiments suggest that this is not so; thus, for example, an animal can be maintained in positive nitrogen balance by intravenous infusion of suitable mixtures of amino-acids; when a partial hydrolysate of protein is used instead of amino-acids, the animal appears to be unable to use much of the peptide material and this is rapidly excreted in the urine[30].

A similar difficulty arises in the study of the nutritional requirements of micro-organisms. Many organisms show loss of ability to synthesize one or other of the twenty amino-acids, but organisms have not been found with absolute growth requirements for peptides. Moreover, when a peptide has been found to have growth-promoting properties, this has usually been shown to be due to hydrolysis of the peptide (see ref. 55). Against this must be set a recent observation of Marshall and Woods[31] that the inhibition of bacterial growth by 4-methyltryptophan can be reversed by tryptophan peptides in a non-competitive manner. They suggest that 4-methyltryptophan inhibits growth by virtue of its ability to inhibit synthesis of tryptophan peptides; thus a supply of peptide in the medium renders the organisms insensitive to 4-methyltryptophan. It must be remembered also that, although there is little direct evidence of the use of peptides by bacteria, it is seldom that these organisms reach their maximal rate of growth except in complex peptide media[32].

It has frequently been claimed that, if peptides played any prominent part in protein synthesis, it should be possible to find peptides in cell extracts. No significant quantity of any peptide other than glutathione has ever been isolated from such extracts, but the value of this as evidence is extremely doubtful. It may be that proteolytic enzymes have no function in protein synthesis; but it is accepted that they must be responsible for intracellular degradation of protein. This degradation must take place by a stepwise process with production of numerous peptides, so that failure to isolate peptides is of no significance except as a demonstration of the inadequacy of our techniques.

## Control of Specificity in Protein Synthesis: the Template Theory

Any scheme of protein synthesis must take into account immunological and chemical evidence that the proteins of each species appear to be unique and structurally distinct from those of other related species. To control synthesis in such a highly specific manner the transpeptidases would be required to show an extremely high degree of specificity. The work of the Bergmann school has shown that pepsin, trypsin, chymotrypsin and papain all have some specificity[33]. Each hydrolyses certain limited groups of peptides; but the recent results of Sanger[34] and of Desnuelle[35] suggest that proteases have different specificities when acting upon larger polypeptide chains. Their specificity in transpeptidation is still largely unknown.

If transpeptidation and coupling of many peptide units are the mechanism of protein synthesis, then many enzymes would be required for the synthesis of a single species-specific protein. These synthesizing enzymes would in their turn have to be synthesized by equally specific enzymes, so that we are faced with an infinitely receding series of enzymes controlling the synthesis of enzymes. However, the specificity of protein structure appears to be inherited within any one species, and the syntheses of proteins would appear, therefore, to be under genetic control.

So long ago as 1909, Bateson[36] suggested that there might be a connexion between genes and enzymes. The concept of the gene was originally a purely formal one, namely, that it is the ultimate unit of hereditary transmission; but in 1937 Haldane[37] suggested that genes had the dimensions of protein molecules. He pointed out that genes must be copied exactly in each succeeding generation and suggested that they behaved as master templates or moulds controlling the specificity of protein structure. This idea was extended still further by Beadle following his study with Tatum[38] of the effect of mutagenic agents on the bread mould, *Neurospora crassa*. After exposing a mould to X-rays, progeny could be isolated with changed nutritional requirements owing to inability to carry out one single step in the synthesis of an essential metabolite. The defect was inherited in a Mendelian pattern as though it were controlled by a single gene mutation, and was shown to be due to lack of a single enzyme. Beadle[39] suggested a one-to-one relationship between genes and enzymes. Since enzymes are proteins, it was a simple extension of this hypothesis to suggest that genes are master templates upon which proteins are synthesized, and that for each specific protein structure there is a template or gene.

Since the segregation of chromosomes during formation of the gamete cells exactly parallels the segregation of genes, it is reasonable to suppose that genes are located on the chromosomes. Both Brachet[40] and Caspersson[41] (using different methods) have shown that chromosomes contain much nucleoprotein and there appears to be good reason for supposing that the ultimate unit of self-reproduction, the gene, is composed either of nucleic acid or protein or an association of the two. Similarly, Stanley[42] has shown that the tobacco mosaic virus, another form of self-reproducing agent, is composed entirely of nucleic acid and protein. The same appears to be true of the bacterial viruses such as *Escherichia coli* phage[43]. Hershey and Chase[44] have labelled coli phage with radioactive phosphorus and sulphur and have shown that when the phage infects the bacterium only the radioactive phosphorus enters the cell and reappears in the phage progeny. Since phosphorus is associated with the nucleic acid fraction of the phage, it is reasonable to conclude that the nucleic acid fraction carries the inherited specificity of the virus. Emphasis on nucleic acid as the controlling factor in transmission of hereditary character and therefore of protein specificity has been increased by the demonstration that type transformation in bacteria can be brought about by cell extracts from other related bacteria and that the active factors in these extracts are nucleic acids[45]. The report of Binkley[45a] that cysteinylglycinase is a polynucleotide directly associates protein metabolism with enzymic activity in a polynucleotide.

In an attempt to take all these factors into account, Dounce[46] has recently outlined an ingenious theory of protein synthesis in which allowance is made for the close association between nucleic acids and inherited character. He suggests that nucleic acids function as templates in governing the order of arrangement of amino-acids in peptide chains as well as the order of nucleic acids in nucleic acid chains. It is supposed that the nucleic acid template is first phosphorylated to give a nucleic acid polyphosphate with a series of energy-rich phosphate bonds; this polyphosphate then reacts either with nucleoside or with amino-acids, thus giving either a double nucleic acid complex or a nucleic acid – amino-acid complex. Linear polymerization of the added nucleosides or amino-acids would then give either a complete replica of the original nucleic acid or a peptide chain, the specificity of which is dependent upon the nature of the original template of nucleic acid [see also p. 1027 of this issue].

This theory has several attractive features: it provides a mechanism for reproduction of the template or gene; it supplies an explanation of the genetic control of protein specificity by nucleic acid; it explains the failure to demonstrate any metabolic function for small peptides; and it provides a mechanism of energy supply for peptide bond formation. In spite of this, there are various facts which do not seem to fit any theory involving control of protein specificity by permanent nucleic acid templates acting as genes.

## Objections to the Template Theory

Caspersson[41] has suggested that protein synthesis takes place at the nuclear membrane; but there is now no doubt that much protein synthesis takes place in the cytoplasmic granules. London, Shemin and Rittenberg[47] have obtained synthesis of hæmoglobin in non-nucleated erythrocytes, and Brachet and Chantrenne[48] have shown that non-nucleated fragments of the marine alga *Acetabularia* can continue to synthesize protein for several weeks. Since proteins synthesized in the cytoplasm are undoubtedly species specific, the direct control of specificity of each protein by a nuclear gene acting as a template seems improbable.

The process of differentiation in higher organisms is also difficult to understand in terms of a controlling template in the nucleus. It would necessarily involve nuclear differentiation of the template, but this seems contrary to the assumption of a one-to-one relationship between templates and genes. There is, in fact, some recent work which suggests that nuclear differentiation does take place (Stern *et al.*[49]). Other apparent exceptions to the control of protein specificity by nuclear templates are adaptive enzyme formation in bacteria and antibody formation in animals. The adaptive enzyme is a new protein not only characteristic of the species but also characteristic of the substrate or inductor (Monod and Cohn[50]); while a new antibody is characteristic not only of the animal immunized but also of the antibody used for immunization.

It is frequently taken as proved that there is a direct correlation between nucleic acid synthesis and protein synthesis, but there is clear evidence that each can proceed in the absence of the other: according to Hokin[51], pancreatic slices can synthesize amylase without simultaneous synthesis of nucleic acid and indeed without turnover of nucleic acid phosphorus; according to Gale and Folkes[52] protein synthesis can be inhibited by antibiotics without simultaneous inhibition of nucleic acid synthesis.

The conception of the gene is essentially an abstract idea and it may be a mistake to try to clothe this idea in a coat of nucleic acid or protein. Perhaps the most striking of all immunological observations is the fact that, despite differentiation, an animal cannot usually be immunized against its own proteins. This would seem to support the idea that if we must have a gene it should have a negative rather than a positive function so far as protein synthesis is concerned. Expressed in terms of protein synthesis, this would mean not that all the proteins of an individual have some common structural pattern, but rather that they are alike in that they all lack some possible peptide sequence which other species have found it possible to synthesize.

## Experimental Approach to the Study of Protein Synthesis *in vivo*

The advent of isotopic tracers and of improved chromatographic methods for the separation of amino-acids and peptides has made possible a more direct approach to the problem. As a suitable system for the study of protein biosynthesis, we have chosen the lactating mammary gland. Numerous earlier attempts have been made to determine the nature of the precursors of milk protein. By measuring the difference in amino-acid content between arterial blood entering, and venous blood leaving, the gland, it was concluded that little more than one-third of the milk nitrogen was supplied as free amino-acids[53]. If this is so, the mammary gland must be capable of transforming blood protein into milk protein, and it therefore seems to us that the gland was a particularly suitable organ for the study of protein biosynthesis (Campbell and Work[54]).

In preliminary experiments lactating rabbits were injected with radioactive amino-acids and the distribution of radioactivity in the blood and milk proteins was followed for seven days. If milk protein is derived from blood protein by minor transpeptidations, the injected radioactive amino-acids would not reach equilibration with intermediary peptides. In this case the radioactivity curves for blood and milk proteins would be expected to be of similar shape. In fact, it was found that the two curves showed no similarity, and that after six hours the milk casein was ten times more radioactive than blood plasma protein. From this result it was clear that the milk was synthesized largely if not entirely from free amino-acids. Other experiments using labelled radioactive plasma suggest that little of the free amino-acid is supplied by breakdown of plasma protein. It was noticed, however, that the casein was always more radioactive than the whey protein, and it thus seemed possible that casein was synthesized entirely from free amino-acids but that whey protein synthesis was by transpeptidation[55]. Whey is, however, a complex mixture of different proteins, and it was equally possible that some whey proteins were synthesized entirely from amino-acids and others obtained directly from blood protein.

By injection of radioactive methionine into an immunized rabbit, Campbell, Humphrey and Work[56] have recently shown that there is indeed direct transfer of antibody globulin from blood to milk; it thus seemed likely that this transfer would explain the low radioactivity of whey as compared to casein. To check this point, a lactating goat was injected with a mixture of four radioactive amino-acids and the milk collected four hours later[57]. The whey proteins were fractionated by the usual methods, and a β-lactoglobulin fraction was obtained which was electrophoretically homogeneous at pH 8·4. The radioactive amino-acids were re-isolated from this protein and compared with the corresponding amino-acids isolated from the casein. Valine and lysine were of the same activity in both proteins, but glycine, serine and methionine were less active in β-lactoglobulin than in casein.

It can be demonstrated on theoretical grounds that if two milk proteins are being synthesized on templates and from the same radioactive amino-acid pool, then the radioactivities of the amino-acids in the two proteins should be equal. The difference found between goat casein and goat lactoglobulin therefore suggested that peptides did, in fact, occur as intermediates in protein synthesis.

## Distribution of Radioactivity at Different Points along a Peptide Chain

Let us suppose that protein is synthesized by stepwise coupling of many peptide units, some peptides being supplied by partial hydrolysis and transpeptidation of existing protein. After injection of radioactive valine, the protein formed would contain this amino-acid at various points along the polypeptide chain. At some points the valine would be derived from the pool of radioactive free valine, but at other points it would be derived from peptides containing valine which is not in equilibrium with the free valine. There could thus be considerable variation in the activity of valine occurring at different points along the chain. If, on the other hand, the protein were synthesized by a template mechanism using only free amino-acids, there would be no substantial difference in the radioactivity at different points along the chain.

Muir, Neuberger and Perrone[58] measured the radioactivity of the terminal valine of rat hæmoglobin after injection of radioactive valine and found no difference between the terminal valine and the mean value for the valine from the remainder of the molecule. This result would be consistent with a template mechanism for globin synthesis. Askonas, Campbell and Work have carried out partial acid hydrolysis of radioactive casein obtained in the goat experiment already described. Preliminary results indicate a variation in the radioactivity of the valine in two different purified valine peptides and thus in activity at different points along the protein chain. In view of the fact that the valine isolations have to be made on a microgram scale, these results should be accepted only with considerable reserve, particularly since two serine peptides isolated from the same hydrolysate contained serine not differing significantly in radioactivity from the mean value for all the serine residues.

While this investigation was in progress, Anfinsen and Steinberg[59] were working quite independently along closely similar lines. They used as their protein-synthesizing system an oviduct mince, which appears to be capable of synthesizing ovalbumin. Radioactive carbon dioxide and radioactive amino-acids were incubated with this mince, and the distribution of radioactivity in the resultant radioactive ovalbumin was determined. Evidence was found for considerable differences in specific activity of alanine at different points along the chain. Again the results should be accepted with reserve, owing to the microgram scale of the work. It should be observed also that these results were obtained with a tissue mince in which transpeptidation could easily have occurred as an artefact; thus, they do not necessarily prove that ovalbumin is synthesized by way of peptide intermediates *in vivo*.

It is apparent from what has been said that there are two main streams of thought on protein synthesis: one derived from the study of isolated enzyme systems and suggesting a stepwise coupling of many small peptide units; the other based on the study of genetic inheritance of protein specificity and preferring synthesis on templates, each template being specific for a single protein structure and probably identifiable with a gene. It is impossible with our present knowledge to choose between these two theories. It may be that choice is the wrong word and that eventually a synthesis of the two ideas will be found to fit the facts. In the meantime, t seems certain that, by the application of such methods as ion-exchange chromatography and isotopic tracer techniques, much more can be learnt about the biosynthesis of proteins. Gale[60] has shown that in esting cells of *Staph. aureus* penicillin inhibits turnover of glutamyl residues of cell protein, but that in growing cells protein synthesis is insensitive to penicillin. It would be unwise, therefore, to assume hat net protein synthesis is identical with protein urnover. If this is admitted, much of the apparent conflict between different types of evidence may well disappear.

# NEWS and VIEWS

## Coronation Honours

The Coronation Honours list contains the following names of scientific men and others associated with scientific activities:

*Viscount:* Lord Woolton, recently Lord President of the Council.

*K.C.B.:* Sir John Cockcroft, chairman of the Defence Research Policy Committee and scientific adviser to the Minister of Defence, and director of the Atomic Energy Research Establishment.

*K.C.M.G.:* Sir James Hance, medical adviser and president of the Medical Board, Commonwealth Relations Office; Stephen E. V. Luke, comptroller for development and welfare in the West Indies and British co-chairman of the Caribbean Commission.

*K.B.E.:* Dr. John A. Carroll, deputy for research and development to the controller of the Navy and scientific adviser to the Board of Admiralty; Major-General Clive S. Steele, for services to engineering in Australia; Prof. Hugh S. Taylor, professor of chemistry and dean of the Graduate School at Princeton University.

*Knights:* Dr. Edward C. Bullard, director of the National Physical Laboratory; Sydney Camm, director and chief designer, Hawker Aircraft, Ltd.; Enoch B. Levy, formerly director of the Grassland Division, Department of Scientific and Industrial Research, New Zealand; George D. A. MacDougall, chief adviser, Statistical Branch, Office of the Paymaster General; Charles R. Morris, vice-chancellor of the University of Leeds; Thomas O. M. Sopwith, for services to aircraft production; Dr. Francis M. R. Walshe, president of the Royal Society of Medicine.

*C.B.:* R. Cockburn, scientific adviser to the Air Ministry; E. T. Jones, principal director scientific research (air), Ministry of Supply.

*C.M.G.:* J. Durward, deputy director, Meteorological Office, Air Ministry; Prof. G. Macdonald, professor of tropical hygiene, University of London, and director of the Ross Institute of Tropical Hygiene; G. W. Nye, deputy agricultural adviser to the Secretary of State for the Colonies; C. T. Saunders, deputy director of the Central Statistical Office, Cabinet Office.

*C.B.E.:* Prof. W. G. Barnard, professor of pathology in the University of London at St. Thomas's Hospital Medical School; F. S. Barton, principal director of electronic research and development, Ministry of Supply; A. G. Beattie, lately inspector-general of agriculture, Nigeria; A. D. J. Brennan, deputy chief veterinary officer, Ministry of Agriculture and Fisheries; R. L. Brooks, Colonial Forest Service, permanent secretary to the Ministry of Agriculture and Natural Resources, Gold Coast; J. N. Brown, assistant comptroller, Patent Office; R. W. Cheshire, deputy chief scientific officer, Admiralty; D. D. W. Cole, assistant controller (production), Atomic Energy Establishment, Risley, Ministry of Supply; W. J. Duncan, Mechan professor of aeronautics and fluid mechanics, University of Glasgow; A. Fage, superintendent of the Aerodynamics Division, National Physical Laboratory; J. E. Hurst, president of the British Cast Iron Research Association; R. G. Lloyd, secretary to the Royal Commission on Awards to Inventors; Dr. A. A. Miles, director of the Lister Institute of Preventive Medicine, London; A. McL. Mooney, deputy director of electrical engineering, Admiralty; D. A. Oliver, metals economy adviser, Ministry of Supply; F. Rayns, director of the Norfolk Agricultural Station at Sprowston, Norwich; F. H. Rowe, director-general, Commonwealth of Australia Department of Social Services; R. L. Scarlett, chairman of the Scottish Horticultural Advisory Committee; Lieut.-Commdr. P. M. Scott, director of the Severn Wildfowl Trust; P. M. Sherlock, vice-principal and director of extra-mural studies, University College of the West Indies; H. S. Young, deputy chief scientific officer, Ministry of Defence.

*I.S.O.:* F. R. Callaghan, secretary, Department of Scientific and Industrial Research, New Zealand; F. R. Ennos, senior principal scientific officer, Government Chemist's Department; W. R. Penhall, secretary of the Aborigines Protection Board, South Australia; E. F. Peck, Colonial Veterinary Service, director of agriculture and veterinary services, Somaliland.

## Prince Louis de Broglie, For.Mem.R.S.

Prince Louis de Broglie was one of the four recently elected foreign members of the Royal Society. We owe to him one of the fundamental ideas forming the basis of quantum theory, the universal connexion between particles and waves. This connexion was obtained by de Broglie in 1924, apparently by a process of pure reasoning from mathematical relations suggested by relativity, and was for a while unsupported by any evidence, except in the case of light-quanta. However, it stimulated Schrödinger to seek for an explanation of the stationary states of atoms as a resonance phenomenon and led him to his famous wave equation, which is the accurate extension to curved orbits of de Broglie's relations for a particle on a straight course. In 1927 came the direct verification of de Broglie's ideas by Davisson and Germer working with slow electrons, and by G. P. (now Sir George) Thomson working with fast electrons, and a new era began in our understanding of atomic processes. The precise relationship of the waves to the particles remains a subject of controversy; what is established is that one must carry out calculations to determine the motion of the waves and then interpret them in terms of probabilities for the particles.

## Geography at Leeds: Prof. A. V. Williamson

Another of the pioneers of university geography is retiring. It is much to be regretted that, for health reasons, Prof. A. V. Williamson is leaving the chair of geography in the University of Leeds, of which he was the first occupant. Trained in the school of geography in the University of Liverpool, he went to Leeds in 1922 as assistant lecturer when the department was small and struggling for adequate recognition. In 1927 he was given the title and status of lecturer as the department grew under his thoughtful guidance; and he became head of the department in 1928. His merits brought him the title of reader in 1933 and he was elected to the first chair of geography in 1944. By this time he had built up a large department which was continually outgrowing the accommodation available. Experience in the First World War widened his interests and directed particular attention to the East; but Prof. Williamson had no narrow outlook in his view of geography and no doctrines on the subject. Prof. Williamson also took a leading part in administration, taking his turn as dean of the Faculty of Arts and as a member of the Senate and Council. To the deliberations of these bodies he brought penetrating criticism, sometimes caustic, but always valuable. He will be much missed by students and staff alike.

## Linnean Society of London: Anniversary Meeting

At the anniversary meeting of the Linnean Society of London held on May 28, the Linnean Gold Medal was awarded to Prof. P. A. Buxton. The following were elected officers for the session 1953–54: *President:* Lieut.-Colonel R. B. Seymour Sewell; *Treasurer:* Colonel F. C. Stern; *Secretaries:* (Zoology) Dr. A. Tindell Hopwood, (Botany) Dr. George Taylor; *New Members of Council:* Mr. J. S. L. Gilmour, Prof. C. T. Ingold, Dr. L. Harrison Matthews, Dr. C. R. Metcalfe and Prof. E. Smith. Prof. Albert Dalcq, of Brussels, Prof. Alfred Sherwood Romer, of Boston, Mass., and Prof. Roger-Jean Heim, of Paris, were elected foreign members; and Robert Mackechnie and Douglas Miller Reid were elected associates *honoris causa*.

## Bibliography of Scientific Aspects of Atomic Energy

The two volumes of "An International Bibliography on Atomic Energy", published by the United Nations Atomic Energy Section of the Department of Security Council Affairs, deal respectively with political, economic and social aspects, and with scientific aspects. Vol. 1 was issued in 1949 and Supplement No. 1 to this volume in 1950 (see *Nature*, 167, 671; 1951). In 1948 and 1949, preliminary mimeographed editions of the component parts of Vol. 2 were issued and circulated among experts of various countries, and in 1951 the printed edition was published. This volume, which listed more than twenty-four thousand articles, books and pamphlets published in all parts of the world during 1925–49, is divided into five main sections: fundamental nuclear science; the physics and engineering of nuclear reactors; the biological and medical effects of high-energy radiations; isotopes in biology and medicine; and applications of radioactive tracers in non-biological sciences and technology. However, the flow of scientific papers on nuclear energy has continued unabated, and periodical supplements to Vol. 2 have accordingly been planned, the first of which has recently been published (pp. 326. New York: U.N. Atomic Energy Section, Department of Security Council Affairs; London: H.M.S.O., 1952. 3.25 dollars, 25*s.* or 14 Swiss francs). The five sections into which it is divided are the same as in the original volume; but the table of contents has been somewhat improved in accordance with suggestions received, and fresh sub-divisions have been introduced to take account of rapidly growing or new research topics. The contents consist of 8,231 items, each item containing the authors' names, the title of the article (with translation if the original is in Russian), abbreviated title of the journal, the volume and page numbers and the date, and two appendixes (one an author index and the other a list of the journals, with addresses, arranged alphabetically under the abbreviations used in the volume). The bibliography does not exclude reviews and general articles, and in this respect is superior to some abstracting journals; but the absence of translations of titles in foreign languages other than Russian will cause difficulty to many users and will hinder further reference to abstracts in abstracting journals.

## Institution of Professional Civil Servants

In his presidential address to the Institution of Professional Civil Servants at the annual delegate conference on May 18, Sir Richard Redmayne commented at some length on the position of the Department of Scientific and Industrial Research as indicated by that Department's recent annual report. The current estimates of the Department, he said, represent not a slight increase on the estimates for 1950–51, but a reduction of about ten per cent, and he urged that reductions in expenditure involving restriction of important and necessary work are not economy but waste. Sir Richard also referred to the Institution's intervention in the decision of the Ministry of Works to dismiss certain artist-craftsmen employed on the restoration of national art treasures, and the reversal of the decision after debate in the House of Lords. The annual report of the Institution's executive committee indicates its intention of seeking to improve the efficiency of the Civil Service by ensuring not only the proper employment of professional, scientific and technical officers, but also their full access to administrative posts on the bases envisaged in the Gardiner Committees' reports. It is also proposed to press (1) the claims for parity between the experimental and the scientific officer classes on one hand and the executive and administrative classes on the other; (ii) the technical grades salary claim deriving from the Gardiner report on the Works Group; and (iii) the salary scales for medical officers based on the Spens reports and the judgment of Mr. Justice Danckwerts.

## Pacific Science Council Secretariat: Report for 1951–52

A report on the work of the Pacific Science Council Secretariat, covering the period March 1951–December 1952 (Bulletin *PS*/52/9; pp. 28; from the B. P. Bishop Museum, Honolulu, 1952), lists the continuing and completed projects of the secretariat, the supplements to the *Information Bulletin* issued during 1951 and 1952, and of the standing committees of the Pacific Science Association. The executive secretary represented the secretariat at the Australian National University's jubilee seminar on "Social Processes in the Pacific", and afterwards visited Singapore, Java, New Caledonia and Fiji. Reference is made to the value of the secretariat's assistance programme for transient scientific workers. The monthly summary, due for release in mid-January 1953, completed one full year of operation of the Pacific Area Communicable Disease Information Service; plague, small-pox, epidemic typhus, cholera, yellow fever, relapsing fever, all of which have already been reported by cable on a world-wide basis by the United Nations World Health Organization, are omitted to avoid duplication. The summary covers the reported incidence of more than thirty other diseases selected on the advice of health officers in the Pacific. A Periodicals Exchange Centre, covering periodicals published between 1920 and 1945, has been established by the secretariat jointly with the Unesco Science Co-operation Offices for South East Asia and for East Asia. The publication of a survey of Pacific scientific expeditions and of a handbook on organizations engaged in scientific research on an international scale in the Pacific was under investigation, while the secretariat was also responsible for organizing the Hawaii symposium on scientific research in the Pacific (held during March 9–10,

1951) and for preparing and distributing the papers and publishing the resolutions of the symposium. The admission of the Pacific Science Association to consultative arrangements with Unesco was approved by the sixth session of the general conference of Unesco (June–July 1951).

## Museums and Education

In the January issue of the *Museums Journal*, Dr. D. A. Allan (of the Royal Scottish Museum, Edinburgh), who was director of the seminar on "Museums and Education" held at Brooklyn Museum, New York, during September 14–October 14, 1952, describes the work and activities of that important gathering. In all, there were thirty-eight members from twenty-four member countries, and the seminar was held under the auspices of the United Nations Educational, Scientific and Cultural Organization. It was agreed at the outset that museums have to save traditions and preach standards in a world where both are threatened. With labels and sympathetic guide-lecturers, there would appear to be no subject involving three dimensions that a museum cannot teach. Books and museum displays were regarded as complementary, but museums can make the great immediate appeal. Many speakers stressed that the development of the emotions is an important element in an individual's education and that here the art museum can achieve much by encouraging sensitivity, response and inspiration. From this the discussions emphasized, first, the value of atmosphere in the individual museum and, secondly, the value of a museum as a point of infection for its community. Museum services must be qualitative rather than quantitative, and warnings were expressed on the inadvisability of expert museum chiefs having to devote valuable time to obtaining financial support and the common fallacy that attendance figures reflect services given. The resolutions passed by the seminar stated the unanimous conviction of the value of museums and appealed for the fullest support for them as educational, cultural and recreational centres.

## Calendar Reform

At the first meeting of the British Section of the World Calendar Association (20 Buckingham Street, London, W.C.2), which was held in London on October 17, Sir Harold Spencer Jones, the Astronomer Royal, gave a lecture entitled "The Calendar, Past, Present and Future". He began by pointing out that the difficulties in devising a satisfactory calendar have been due to the incommensurability of the three natural periods of time, the day, the month and the year, and he followed with a short survey of the various calendars—Egyptian, Babylonian, Greek, Jewish, Roman, Gregorian and Mahommedan—giving a brief reference to the confusion introduced by these different systems. In general, Sir Harold favours the adoption of the world calendar, which has the merit of being simple, stable and perpetual (see *Nature*, 169, 961 and 1083; 1952). In this scheme, the year is divided into four equal quarters of ninety-one days, which would leave a day over in normal years and two days in leap years. Each quarter is divided into thirty-one, thirty and thirty days respectively, commencing with a Sunday and ending with a Saturday, and containing exactly thirteen weeks, the second and third months beginning on Wednesday and Friday, respectively. As there would be a day left over in normal years, this would follow December 30 and be named 'world day'; in leap years the other extra day would come in between the first and second halves of the year and be named 'leap day', and each of these days would be a world holiday. Religious objections which have been advanced against the scheme are not considered insuperable, and Sir Harold expressed the hope that the scheme, which is to be discussed by the United Nations Organization, will be seriously considered on its merits. He ended with an appeal for the widest measure of support for the world calendar, a reform which will only be possible if there is a vigorous campaign to expound its advantages to the ordinary man.

## Careers in the Petroleum Industry

A number of booklets dealing with careers and prospects for professional men in the Royal Dutch/Shell Group of Oil Companies have been published by the Shell Petroleum Co., Ltd. (St. Helen's Court, London, E.C.3), and they can be recommended particularly to parents, headmasters and potential candidates for appointments in this field. In one, "Careers in the Petroleum Chemical Industry" (pp. 22; 1952), the subject-matter is divided into two sections, general information and careers. The former gives details of the Group's organization and work, incidence of National Service, conditions of pay, promotion, service overseas and how to apply for employment. Under the section on careers is explained the growth of this modern phase of petroleum technology, the marketing of special products, and areas where chemical manufactures are concentrated, concluding with a brief description of research and development laboratories, the production of intermediates and marketing areas. Another brochure, "Careers in the Royal Dutch/Shell Group" (pp. 82; second edition, 1952), goes into the oil industry in more detail, embracing the range of different occupations in the industry as a whole and covering all initial information that anyone having this vocation in mind will benefit by careful perusal. These publications are lavishly illustrated in a manner that, combined with excellent texts, brings home to the reader in straightforward wording the vast ramifications of this industrial scene as it exists to-day all over the world; no less are the great opportunities awaiting those who lean either to administrative or, perchance, more adventurous activities at home or overseas.

## Guide to Chemicals used in Crop Protection

The number and variety of chemicals used in plant protection from insect pests, diseases and weeds has vastly increased during recent years. The nomenclature of the many compounds employed is most involved, and few would claim to be thoroughly conversant with them, while the rapidity with which progress in the subject continues renders it impossible for the text-book writer to keep abreast with the latest developments. Many will therefore welcome the issue by the Canadian Department of Agriculture of a publication entitled "Guide to the Chemicals used in Crop Protection", by H. Martin and J. R. W. Miles (pp. 236; from the Science Service Laboratory, University of Western Ontario, Sub Post Office, London, Ontario; 1952). This mimeographed publication gives a concise account of some 177 chemicals, including in each case their full structural formula, history, manufacture, properties (physical, chemical and biological), formulation and method of analysis. The arrangement is alphabetical and in loose-leaf form to facilitate addition or revision. An index is also provided so that reference can be made by means of the alternative name if the full one is unknown. The precautions needed in the use of the compounds are stated where applicable.

## Age and Evolution of the ζ Persei Group of *O*- and *B*-Type Stars

A PAPER on "The Age and Evolution of the ζ Persei Group of *O*- and *B*-Type Stars", by A. Blaauw, has been published in the *Bulletin of the Astronomical Institute of the Netherlands* (11, 433; 1952), and this follows up a previous publication (No. 363; 1944), in which the moving cluster of early-type stars including, among others, the bright stars ζ and ξ Persei, was described. Further studies, which are dealt with in the present paper, lead to some interesting conclusions with reference to the evolution of this group and to an estimate of the age of its members. The principal observational data concerning the stars of the group are contained in a table, and two figures show the adopted linear relation between the components of proper motion and the co-ordinates of the star. The slope of this relation is taken as a measure of the apparent expansion, and this relation should exist in the following circumstances: the present dimensions of the group are large compared with the dimensions at the time when the stars began their independent motions; and these motions started at the same time and have since been uniform. In the circumstances the linear relation is independent of the distribution of the sizes and of the directions of the velocities, and on the above two assumptions it was found that the time, which has elapsed since the beginning of the uniform motions is 1·3 million years. It is admitted that this seems surprisingly short when compared with the period of revolution of the stars in the solar neighbourhood around the galactic centre—about 220 million years—or with the current estimates of the age of the sun. It would be possible to allow a longer time, however, if the condensation of the interstellar material into stars took place already during the process of contraction of the original cloud, but the difference would amount to only a few hundreds of thousands of years, so the figures given above must be accepted as approximately correct. In addition, the presence of high-luminosity stars like ζ and ξ Persei points to a small maximum age which can be estimated on the assumption of radiation of energy in the past proceeding at the same rate as at present, the source of the energy being the transformation of hydrogen into helium. Maximum ages of 7·9 and 7·4 million years for ζ and ξ Persei, respectively, are thus found, but for various reasons the true ages may be much less. An interesting feature of the group is the presence of a very small cluster of faint stars immediately south of o Persei, and the photographically determined proper motions for this cluster are shown in a table.

## Latin American Course in Santiago on Electrophoresis

THE second of a series of international training courses, in collaboration with leading Latin American research institutions, in order to introduce and improve the use of modern techniques and methods in scientific research in Latin America, organized by the Unesco Science Co-operation Office for Latin America, was inaugurated in Santiago de Chile on April 20. The course, which was full-time and lasted for three weeks, dealt with electrophoresis and was attended by research workers from Argentine, Brazil, Chile, Colombia, Ecuador, Peru, Uruguay and Venezuela. The instructors for the course were drawn from the University of Chile with Prof. Dan H. Moore, head of the Laboratory of Electrophoresis of the College of Physicians and Surgeons, Columbia University, New York, as guest lecturer. The first of these courses dealt with the methodology of radioisotopes in biological research and was held in the Laboratory of Radioisotopes of the University of São Paulo, Brazil, during January 14–February 28 (see *Nature*, February 14, p. 289). The next two courses planned by the Unesco Office will deal respectively with electron microscopy and chromatography, and further information can be obtained from Centro de Cooperación Científica para América Latina de la Unesco, Bulevar Artigas 1320, Montevideo, Uruguay.

## Biology and Productivity of the Sea

A SYMPOSIUM on "The Biology and Productivity of the Sea" will be held, under the auspices of the Institute of Biology, in the rooms of the Royal Geographical Society during September 18–19. The subjects include zoology, botany, fisheries and oceanography, and papers will be contributed from the British Museum (Natural History); National Institute of Oceanography; Fisheries Laboratory, Lowestoft; Marine Laboratory, Aberdeen; Marine Laboratory, Plymouth; "Discovery" Investigations; Institute of Seaweed Research; Fisheries Experiment Station, Conway; Food and Agriculture Organization; Colonial Office. Other authors in Copenhagen, Malaya, Southampton and Cambridge are contributing. The chairmen of sessions are: Dr. E. Hindle, Prof. F. E. Fritsch, Dr. F. N. Woodward, Mr. F. S. Russell and Mr. H. J. Johns. Further information can be obtained from the General Secretary, Institute of Biology, Tavistock House South, Tavistock Square, London, W.C.1.

## Announcements

THE Albert Medal of the Royal Society of Arts for 1953 has been awarded to Dr. E. D. Adrian, Master of Trinity College, Cambridge, for his outstanding contributions to neuro-physiology. This Medal, which is the highest award in the gift of the Royal Society of Arts, was instituted in 1864 to commemorate the presidency of the Prince Consort during 1843–61, and is given annually for "distinguished merit in promoting Arts, Manufactures and Commerce".

THE following appointments have been made in the Queen's University of Belfast: Dr. I. T. A. C. Adamson, formerly of Princeton University, to a lectureship in pure mathematics; Dr. A. R. Pinder, of Magdalen College, Oxford, to a lectureship in organic chemistry.

THE Heineman Foundation for Research, Educational, Charitable and Scientific Purposes, Inc., is offering a prize of 5,000 dollars, known as the "Dannie Heineman Prize", to be awarded every three years to the author of an outstanding book or manuscript in the mathematical or physical sciences. The object of the prize is to encourage the writing of books on a high scientific level which open up important fields of research. Those wishing to compete for the prize should submit two copies of the book or manuscript in question to the Secretary of the Foundation, 50 Broadway, New York 4, N.Y., not later than December 31, 1955.

# ROCKETS

THE subject of rockets is one that has attracted considerable popular attention during the post-war years, but on which very little reliable technical information has been available. It was, therefore, an attractive and interesting topic for a discussion meeting on April 24 at the Society for Visiting Scientists. Introductory talks were given by the chairman, Prof. A. D. Baxter, Mr. I. Lubbock and Dr. A. C. Merrington, all of whom have had long experience in the rocket field, and afterwards a general discussion ranged over a wide variety of problems of scientific interest.

In opening the meeting, Prof. Baxter emphasized the propulsion side of the subject and reviewed the relationship of rocket propulsion to other forms of power plant. The major distinction is that the latter are air-swallowing; but the rocket motor is practically independent of the atmosphere. Consequently, the propelling force developed by piston engines, gas turbines and ram jets falls off as the altitude increases, whereas the rocket motor force actually increases slightly. At the same time, the dimensions of a rocket motor are very much less for the same thrust, and its compactness gives it advantages of low weight and air resistance. These are offset to some extent by the large consumption of propellant resulting from the need to carry its own oxidant. Such features make the rocket motor eminently suitable for short-duration propulsion at extreme speeds and altitudes; hence its role in aircraft, guided weapons and, in the future, space-craft. Because of the high fuel consumption, it is probable that new flight techniques will evolve as, for example, the use of a combined ballistic and extended glide path. These would introduce new problems—how to deal with the very high skin temperatures of the rocket at high speeds, the cabin air-conditioning for passengers, the physiological effects of prolonged accelerations and periods of weightlessness and so forth.

Mr. Lubbock, who followed, gave an account of the early methods of designing liquid propellant rocket motors, which were contrasted with those using solid propellants. The selection of an oxidant was made from the three best known: liquid oxygen, hydrogen peroxide and nitric acid. All three were used by the Germans during the Second World War and each has problems peculiar to itself. Liquid oxygen is attractive in many ways; but its low boiling point introduces engineering problems of storage and transfer to the combustion chamber. Conditions in the latter are much more severe than in other internal combustion engines—the gas pressure is at least 300 lb. per sq. in. and the temperature is of the order of 3,000° K., compared with the normal gas turbine maximum pressures and temperatures of approximately 80 lb. per sq. in. and 1,150° K. respectively. The thermodynamics of rocket combustion is therefore complicated by dissociation, and heat transfer calculations demand data well beyond the limits of experimental knowledge.

From this point, Dr. Merrington followed with an explanation of rocket motor testing and research procedure. Contrary to the usual ideas, he said, the greater part of the testing and development is done statically, and only in the later stages is it necessary to consider flight testing at one of the rocket ranges. As in most experimental work, some risk of component failure exists with new developments, and proper precautions have to be taken. The risks arise mainly from the concentrated potential energy of an unburnt propellant mixture. This energy is of the same order as in high explosives, and if its liberation is not controlled, explosion can occur. To reduce the consequences of this, static testing is carried out in reinforced concrete cells. Measurements of thrust, propellant flow-rate, and the associated liquid and gas pressures are made, but no satisfactory methods of measuring the high combustion temperatures have been devised. Because of the rapid rates of change in the quantities to be measured, especially during starting, electronic recording is frequently adopted. In flight, the operation of the motor is studied chiefly by telemetry, the main information required being obtained indirectly in the form of pressures recorded graphically.

In the discussion which followed, a variety of points were made and questions asked. There was a natural interest in any possible uses of rockets other than for warlike purposes. The best known has been the life-saving rocket, in operation for more than a hundred years, which carries a line from shore to ships in distress. Among others enumerated were the mail-carrying rocket which had been tried in places where the topographical features encouraged it, such as across mountain ranges or stretches of water, high-altitude sounding rockets for studying upper atmosphere conditions and, at the other end of the speed and height-scale, assisted take-off rockets for transport aircraft operating from short runways or in conditions where the main engines could not give sufficient thrust. Mention was also made of rocket techniques applied to the drilling of oil bore-holes, the shaping of metal articles, and the operation of wind tunnels; the last relies on the ejector pump action of the high-velocity rocket exhaust gases entraining air from the tunnel. Such a tunnel would be expensive to operate frequently, but would save capital outlay on conventional electric motors and fans if only required intermittently. The principle has been applied to boundary-layer suction from aircraft wings to improve lift during take-off and landing. Another case of intermittent use requiring short periods of high-pressure gas generation is in driving small gas turbines used as engine starters.

The noise emitted by rocket motors was discussed at some length. This noise is made up from two sources—combustion and exhaust jet. Combustion noise is common to all types of engine in greater or lesser degree, and its level is dependent upon variables such as mixture ratio and combustion chamber loading. No satisfactory explanations relating the observed results in different forms of engine has yet been offered. Exhaust noise is a function of the shear velocity gradient between the jet and the atmosphere. Attempts to reduce this usually cause a loss of thrust. In cases where burning of fuel continued in the exhaust jet after leaving the motor, the suppression of this after-burning has produced a noticeable reduction in noise-level. Finally, it was remarked that, in most cases, rocket noise would be only of very short duration before the source would reach a height at which it would not be a serious trouble to ground observers.

The reliability of rockets, bearing in mind the *V2* firing failures, was queried; but it was stated that there is no fundamental reason why they should not be perfectly safe, and a number of aircraft applications were quoted in support. The problem of jettisoning assisted take-off or booster rockets in flight without damage to the motors or the populace below was also considered. A suggestion that rocket motors might be used for assisting gliders to extreme heights so that observations of meteorological interest could be made without the corrections necessitated by the transient conditions inherent in the sounding rocket was considered impracticable. An alternative proposal was a balloon with some rocket thrust available for directional control. Among other facts brought out was that the present maximum altitude reached by a rocket is 240 miles.

The chairman summarized the discussion by stating that rocket motors could give advantages wherever simplicity is needed, wherever high energy for short periods is demanded and wherever other power plants could not operate because of lack of air. The meeting then concluded with a short colour film of some rocket motor tests, both in flight and on the ground.

# RADIOISOTOPE TECHNIQUES IN INDUSTRY

THE wide use of radioisotopes in medical research has received considerable publicity; but their field of application is by no means limited to medicine, and consultations between nuclear physicists conversant with radioisotopes, and workers in other branches of science and engineering soon reveal numerous important problems that can be tackled successfully by the use of these substances. The international conference on radioisotopes held during July 16–20, 1951, at Oxford, under the auspices of the Atomic Energy Research Establishment, Harwell, is an outstanding example of the value of such consultations. In all, ninety-eight papers were presented, grouped under the main headings of therapy and diagnosis, biochemistry, agriculture, and industrial and allied research applications, and divided into thirty separate sessions. The complete text of the proceedings of this isotopes techniques conference, including the chairmen's addresses, the papers presented and the discussions on them, is to be published in two volumes, the first of which, Vol. 2, covering Sessions 21–30 inclusive and devoted to industrial and allied research applications, has now appeared*.

For the first two Sessions, 21 and 22, dealing with general and metallurgical applications, Dr. B. Goldschmidt, of the Commissariat à l'Énergie Atomique, Paris, was in the chair, and in his opening remarks he expressed gratitude to Great Britain for the liberal policy adopted with regard to the release and distribution of radioisotopes for industrial purposes to foreign countries; in addition, he paid tribute to Dr. H. Seligman, the head of the Isotopes Division at Harwell, for initiating the conference. Of the seven papers presented in the two sessions, the two main ones were by Dr. Seligman on types of applications of radioisotopes, and by Dr. R. W. Cahn on radioisotopes applied to metallurgical research. Dr. Seligman briefly reviewed the various industrial applications, mentioning, in particular, gamma radiography, static eliminators and thickness gauges. He pointed out that tracers have not been used as extensively as they might have been, particularly in problems of process control. Dr. Cahn distinguished between what he called microscopic applications in metallurgy (such as tracer methods for the measurement of self-diffusion in metals, and autoradiography for the determination of tracer elements in alloy sections) and macroscopic applications, in which the normal experimental or industrial procedure is followed, but where, at some stage, tracer elements are introduced.

Session 23 was devoted to gamma radiography, and Mr. W. N. Blacklock, of the Ministry of Supply Aeronautical Inspection Directorate, who presided, referred to the prominent part taken by radiography in non-destructive testing. He stated that the present relatively inexpensive and abundant supply of radioisotopes largely eliminates the need for heavy and costly X-ray equipment for the testing of heavy metal components. Five papers dealt with gamma radiography tests of iron and steel castings and inspections of metal welds. These were preceded by an interesting short paper by Mr. W. S. Eastwood on the handling of radiographic sources, in which he mentioned that, in addition to radium and radon, only three radioisotopes—cobalt-60, tantalum-182 and iridium-192, all metals—are in current use. They are prepared by the Atomic Energy Research Establishment, Harwell, in the form of small cylinders of standard sizes. Shorter-lived isotopes are also obtainable; but these are irradiated to order at Harwell in the size required and to the necessary activity. With regard to transport of the strong sources, it has to be remembered that the limits of radiation at a package surface set by British Railways are even more stringent than those of airline companies, and thus radiographic sources are transported inland by motor-car and are sent to Continental users sometimes by sea.

Mr. B. Schuil, who spoke about radioisotopes in radiography and measurements of wall thickness, made an interesting reference to the psychological effect that radiographic control of welds has on welders who are working far away from their workshops. With radioisotopes, control and test of pipe welds are possible in the field even under the worst conditions, and it was found in Holland that when welders were aware that a radiographic inspection was in force the percentage of bad welds fell from 80 to 20 per cent. Finally, to wind up the Session, Dr. J. S. Blair described some of the safety precautions that are necessary when radioisotopes are handled.

In Session 24, on counting techniques, Dr. S. G. Cohen and Dr. D. Carmi described counters with thin plastic walls for the detection of X-rays, and Mr. H. Herne showed how, by the use of the commonly known, but not commonly employed, property of radioisotopes—namely, the random nature of the radioactive disintegrations themselves—the isotopes could be used in an analogue computer for stochastic problems. Mr. J. L. Putnam then discussed the very important but somewhat thorny problem of the absolute measurement of the activity of radioisotopes. He stressed the need for generally accepted standards of radioactivity and mentioned some of the intercomparison measurements and absolute measurements which are being made in

---

* Ministry of Supply. Radioisotope Techniques: Proceedings of the Isotope Techniques Conference, Oxford, July 1951, sponsored by the Atomic Energy Research Establishment. Vol. 2: Industrial and Allied Research Applications. Pp. iv+177+33 plates. (London: H.M.S.O., 1952.) 25s. net.

Britain. (Some of the results of these measurements have since been published; see *Nature*, 170, 916; 1952.)

The study of solid reactions is probably one of the main applications for radioactive tracers in physical chemistry; and in Session 26, on chemical applications, the first paper, by Dr. R. Lindner, dealt with this subject. Another interesting paper in this Session, by members of the Kodak Research Laboratories, was on the determination of silver in photographic images using radioactive iodide (iodine-131). Where a large number of analyses is required, the radio-iodination method has a distinct advantage over the potentiometric method and is to be preferred where only a small image is available, as in X-ray crystallographic patterns, or when the optical density is low.

The remaining four Sessions (27–30) were devoted respectively to ion exchange, non-destructive testing, static elimination and radioactivation analysis. Mr. K. Fearnside, of Isotope Developments, Ltd., Aldermaston, described four instruments: the transmission beta-ray thickness gauge used in paper, plastic sheet and metal foil production; the reflexion beta-ray gauge for the measurement of the thickness of coatings and liquid films; the gamma-ray thickness gauge applied to thick or hot-rolled metal strip; and the package monitor used to check the contents of sealed packages as they leave the packaging machine. Mr. G. Syke dealt in more general terms with the problem of inspection and gauging with ionizing radiations. Fog-making on certain kinds of fabrics due to static electricity forming on the fibres can be prevented by dissipating the static when it occurs before it has time to become a nuisance. The static may be made to leak away either through the textile itself or through the surrounding air. Ionizing the air by means of a radioactive substance is a most successful method; and in his paper on radioactive static eliminators for the textile industry, Dr. P. S. H. Henry, of the Shirley Institute, discussed thoroughly the question of static on textiles and the relative merits of alpha- and beta-ray static eliminators. Finally, Mr. A. A. Smales gave some indications of the scope of radioactivation analysis, the essential basis of which is that an element is detected and determined by the formation of a radioactive nuclide which is then subjected to radioassay, and Prof. G. Chaudron described some work on the analysis of traces of sodium and copper in high-purity aluminium by pile activation.

## BREEDING-BACK OF THE TARPAN

BEFORE the existence of human culture a number of different kinds of wild horses existed in Europe and Asia. Of these only one is extant to-day. This one was discovered by the Russian Przewalski in the desert-like steppes of Zungaria in western Siberia. Like most steppe-dwelling animals, the Przewalski wild horse is red-brown in colouring and light underneath. As a legacy from its forbears it still carries zebra-like stripes at the backs of the legs which show up very clearly in the summer coat. The discovery of the last remaining species of wild horse was followed by the news that in the 1920's it had become extinct in the free state. To-day only a few are left scattered in various zoological gardens, and none is breeding except in the sixteen-head Munich herd. It is on this herd that the hopes of preserving the species must rest.

If the species is not preserved, apart from its own interest, one of the most interesting animals of to-day will have become extinct. One of the European wild horses, the mouse-grey, for which the Russian name of tarpan has been adopted, was, in historical times, still extant over large areas of Europe (*Oryx* (Journal of the Fauna Preservation Society), 1, No. 7; November 1952).

In the first half of the past century it was still numerous in the steppes of the Ukraine north of the Black Sea. In 1876 it became extinct, leaving few traces of its existence. The tarpan was different from the Przewalski wild horse not only in colouring but also in build. The Przewalski has strong thick bones and an almost disproportionately heavy skull with narrow forehead which, many investigators believe, is the reason why the heavy carthorses of to-day are descended from this type. The tarpan has much finer bones and a short light head and is probably the progenitor of swift riding horses.

Distinguished for his successful efforts in breeding back the wild aurochs, Heinz Heck, director of the Tierpark Hellabrunn, Munich, has also successfully bred-back the tarpan. Mares from Iceland and Gothland that were markedly like tarpans were crossed with a Przewalski stallion; the resultant crosses were mated with one another and, in 1933, from this stock emerged the first foal with a mouse-grey tarpan colouring. Other foals followed, and through resultant crossings there is to-day a considerable stock of back-bred tarpans in the Tierpark, Hellabrunn.

## MICROSCOPY OF PLANT ASHES

THE statement that a microscope magnifies four hundred times never quite conveys a true idea of the wealth of detail that can be seen at this magnification. Perhaps only when the incredibly small fragments of material on a cosh, the minute amounts of blood or hair and other such negligible 'small dust of the balance', appear as important items of evidence in criminal proceedings is it realized how valuable is this instrument in the examination of such unpromising material.

One would, however, be pardoned in assuming that even the microscopist would have to admit defeat when dealing with material that had been so thoroughly incinerated that only an ash remained. However, in 1920, the Austrian botanist Hans Molisch investigated the structures left after incinerating plant material and showed that the ash still retained definite structural features. Prof. Gosta Edman, now professor of botany and pharmacognosy in the Royal Pharmaceutical Institute, Stockholm, was then a pupil of Molisch and later set out to investigate these 'ash pictures' systematically and has since published numerous papers on the subject. Recently he was awarded the Hanbury Memorial Medal of the Pharmaceutical Society of Great Britain which, in conjunction with the Linnean and Chemical Societies, periodically makes the award for "high excellence in the prosecution or promotion of original research in the Natural History and Chemistry of Drugs". After receiving the medal, Prof. Edman gave an account of his work on ash pictures (*Pharm. J.*, 170, 189; 1953).

Naturally, a good proportion of the work has been concerned with powdered or broken vegetable drugs, and Prof. Edman claimed that his method of examination is sometimes more convenient than normal ones. The drug is strongly heated until the bulk of the tissues is completely burned away; the characteristic appearance of the mineral skeletons of the cell walls and the cell contents is then revealed. The method, however, has several other important applications, especially in criminal proceedings involving suspected arson. Further, the examination of prehistoric materials by this method has been of some assistance to archæologists. Thus, the examination of the charred vegetable matter in a Chinese clay-sheard, about five thousand years old, showed it to consist mainly of the remains of the leaf blades of *Oryza sativa*, the same plant used to-day for the production of rice. In the same way, fragments of cereals, medicinal herbs, etc., have been identified in the intestines of Egyptian mummies. Prof. Edman has also examined the ash pictures of about 375 related plant species in relation to their phylogeny and taxonomy and has published many original articles on this subject in the botanical literature. He concludes that extensive silicification of the cell wall is associated with primitive characters.

J. W. Fairbairn

# OBSERVATIONS AT THE ROYAL OBSERVATORY, GREENWICH

THE observations made at the Royal Observatory, Greenwich, during 1937 in astronomy, magnetism and meteorology, under the direction of Sir H. Spencer Jones, have been published in a single volume (pp. *A*62+*B*21+*C*200+*D*66+*E*46+40. London: H.M.S.O., 1951. £6 net), which is divided in five sections, *A–E*, as follows: meridian astronomy, equatorial observations, photo-heliographic observations, magnetic observations and meteorological observations.

The first section includes work on the transit circle and on the time service; in the former are the results of regular observations of the sun, moon, major planets and minor planets Juno, Ceres, Pallas and Vesta, and in the latter is given a short account of the new equipment and advances in the technique since the publication of the "Time Service Results" in 1936. The section on equatorial observations contains a table on the observations of double stars made at the Observatory which includes not only all pairs observed during 1937 but also all previously unpublished measures of earlier years. A systematic difference was found for close pairs between the results of the filar micrometer and of the comparison image micrometer (brought into use towards the end of 1937), and the table indicates which instrument was used.

The second section, on photo-heliographic observations, is by far the largest of the five sections. The positions and areas of sunspots and faculæ for each day during the year 1937 is the first of seven tables in this section, the photographs being taken at the Royal Observatories of Greenwich or of the Cape, and at the Kodaikanal Observatory (a negative transparency for November 3 was supplied by the Mt. Wilson Observatory to fill a gap in the series). The other tables are: a general catalogue of groups of sunspots for 1937; ledgers of areas and positions of groups of sunspots (recurrent groups and non-recurrent groups); total areas of sunspots and faculæ for each day; mean areas of sunspots and faculæ for each rotation and for the year; mean heliographic latitude of spots for each rotation and for the year; and observations of solar flocculi made with the spectrohelioscope.

The introduction to the section on magnetic observations describes the magnetic station at Abinger, with its instruments, methods of observation, magnetic reductions and arrangement of results; these results are listed in fifteen tables, and there are notes for each month of 1937 which briefly summarize the magnetic conditions exhibited by the traces of declination and horizontal and vertical intensity during the year. Finally, a description of the instruments and the meteorological reductions is given in the section on meteorological observations; several changes were made in the 1934 volume as regards the notation for clouds and weather, this being done to bring the symbols into general accordance with those in use at the British Meteorological Office.

All the above-mentioned work by the Royal Observatory, Greenwich, was continued during 1938, and an account of it has now been published; the volume is similar in all respects to that for 1937. Another series of Greenwich observations which has at last been published is Vol. 2 of "Observations of Colour Temperatures of Stars:- Relative Gradients" (pp. 115; London: H.M.S.O., 1952; 25*s*. net); this volume covers the years 1933–38 and is a sequel to the observations of 1926–32, published in Vol. 1.

# UNITED STATES NATIONAL ACADEMY OF SCIENCES

AT the annual general meeting of the National Academy of Sciences, held in Washington, D.C., during April 27–29, the following officers, new members and foreign associates were elected.

*Vice-President:* George W. Corner, director, Department of Embryology, Carnegie Institution of Washington, Baltimore, Maryland, for a four-year term.

*New Members of Council:* Edwin B. Wilson, professor of vital statistics, Harvard School of Public Health, Boston; and Hugh L. Dryden, National Advisory Committee for Aeronautics, Washington, D.C.

*New Members:* L. V. Ahlfors, professor of mathematics, Harvard University; P. Bailey, professor of neurology and neuro-surgery, University of Illinois School of Medicine; H. A. Barker, microbiologist, University of California, Berkeley; V. H. Benioff, professor of geophysics, California Institute of Technology; J. H. Bodine, professor of zoology, University of Iowa; L. Brillouin, director of electronics education, International Business Machines Corporation, New York; M. J. Buerger, professor of mineralogy and crystallography, Massachusetts Institute of Technology; H. E. Carter, professor of biochemistry, University of Illinois; D. M. Dennison, professor of physics, University of Michigan; J. P. Den Hartog, professor of mechanical engineering, Massachusetts Institute of Technology; J. W. M. DuMond, professor of physics, California Institute of Technology; C. Eckart, director of the Marine Physical Laboratory, University of California, San Diego;

R. Emerson, research professor in botany, University of Illinois; J. F. Enders, chief, Division of Infectious Diseases, Children's Hospital, Boston; P. J. Flory, professor of chemistry, Cornell University; G. Gamow, professor of theoretical physics, George Washington University, Washington, D.C.; V. Hamburger, professor of zoology, Washington University, St. Louis; C. E. Hille, professor of mathematics, Yale University; J. O. Hirschfelder, professor of chemistry, University of Wisconsin; J. G. Horsfall, director, Connecticut Agricultural Experiment Station, New Haven; E. H. Land, president, Polaroid Corporation, Cambridge, Mass.; D. P. C. Lloyd, member, Rockefeller Institute for Medical Research, New York; H. W. Nissen, associate director, Yerkes Laboratories of Primate Biology, Orange Park; D. Rittenberg, associate professor of biochemistry, Columbia University; J. F. Schairer, physical chemist, Geophysical Laboratory, Carnegie Institution, Washington, D.C.; T. Shedlovsky, member, Rockefeller Institute for Medical Research, New York; J. C. Street, professor of physics, Harvard University; M. Tishler, director, Development Research Department, Merck and Company, Inc., Rahway, N.J.; H. G. Wood, head of the Department of Biochemistry, Western Reserve University; and R. B. Woodward, professor of chemistry, Harvard University.

*Foreign Associates:* J. H. Oort, director, Leyden Observatory; and Wilder Penfield, professor of neurology and neurosurgery, McGill University, and director, Montreal Neurological Institute, Montreal.

# KOSSUTH PRIZES IN HUNGARY FOR 1953

WINNERS of the 1953 Kossuth Prizes in Hungary, which are given for outstanding work during the past year, have recently been announced. These Prizes carry monetary awards of various amounts (1,000 forints is approximately £3), and those given for scientific, technological or medical work include the following. A Prize of 50,000 forints to Frederick Riesz, president of the Mathematical Section of the Hungarian Academy of Sciences, for his book entitled "Lesson of Functional Analysis", written in conjunction with B. Nagy, in which theories are developed that are of great importance in the development of mathematics. Prizes of 20,000 forints to: B. Nagy, correspondent member of the Hungarian Academy of Sciences, for his part in the joint work with F. Riesz, mentioned above; F. Ratkovszky, for work on the electrification of the country and for making a 'diabolo-transformer'; K. Novobatzky, professor of theoretical physics in the University of Budapest, for research on the quantum theory; J. Egerváry, for work in applied mathematics on the theory of differential equations, particularly in the development of a method for computing the critical limit of rotations of rotors in turbo-generators; Z. Csűrös, academician, for results achieved in the study of heterogeneous catalysis; A. Ábrahám, correspondent member of the Academy, for research of the nerve tissues, based on the teachings of Pavlov; Z. Gyulai, correspondent member of the Academy, for research work on the boundary layers of crystals and solutions, and for the production of artificial quartz crystals; V. Keilwert, chemical engineer at the Láng engineering factory for directing the planning of the Debrecene penicillin factory; J. Proszt, professor in the Inorganic Chemistry Institute, for pioneering research in the preparation of organic silicon compounds; L. Kulin, specialist in children's diseases, for results achieved in curing tuberculosis in babies; G. Bárczi, director of the Budapest Therapeutical Teachers Training College, for results achieved in basing Hungarian medical teaching and education on the natural sciences and for applying Pavlovian theories; J. Kollonitsch, departmental head of the Medicine Industry Research Institute, for medical research and work in the pharmaceutical industry, particularly in the new preparation of 'Treomycin' for the treatment of whooping cough, typhoid and dysentery.

Prizes of 10,000 forints to: P. K. Károly, correspondent member of the Academy, for his text-book entitled "The Factory Science of Electrical Machines", and for research; L. Verebély, professor at the Technical University, for his handbook entitled "Transmission of Electrical Energy", and for work on electrification; J. Urbanek, director of the Central Research Laboratory of the Electrical Industry, for his text-book entitled "Introduction to the Technical Science of Theoretical Electricity" and for his new method of cooling turbo-generators by refrigeration; S. Müller, correspondent member of the Academy, for work in organic chemistry in connexion with the industrial production of synthetic materials; A. Romwalter, university professor, for research in coal chemistry; K. Rauss, professor at the Pécs Medical Science University, for research into children's diseases and dysentery inoculation; L. Fuchs, university dean, for work on the theory of structural algebra.

# HYDRATION OF METAL CATIONS

By DR. E. GLUECKAUF and G. P. KITT
Atomic Energy Research Establishment, Harwell, Berks

MEASUREMENTS have been made by the isopiestic method of the water content of hydrogen and metal polystyrene sulphonates at different water vapour pressures and at two different temperatures, using concentrated sulphuric acid solutions as vapour pressure standards. This permits of a calculation both of water-activities (see curves *A* and *B*) and of the differential heats of hydration $\bar{H}$ of the ions (curve *C*). The polystyrene sulphonates of monovalent ions show in this respect great similarity to the behaviour of strong 1 : 1 electrolytes such as, for example, lithium chloride or perchloric acid and, as has been shown previously[1,2], can be considered as concentrated solutions of electrolyte in their swelling water. Indeed, the trend of $\bar{H}$ for the hydrogen polystyrene sulphonate (curve *C*) is very similar to that of concentrated sulphuric acid[3] in the range where the latter may be regarded as a monovalent acid, $H \cdot SO_4H$ (see curve *D*). For a study of concentrated solutions the polystyrene sulphonates have a great advantage over most aqueous solutions: they can be concentrated without crystallization to any desired strength (100 molal and above) and thus provide information on the interaction of water with all kinds of ion at high concentrations which are normally attainable for acids only. The polystyrene sulphonate of very low cross-linkage (0·5 per cent divinyl benzene) was obtained by courtesy of Dr. K. W. Pepper, Chemical Research Laboratory (Department of Scientific and Industrial Research), Teddington.

Attempts to fit water-activity data of concentrated electrolyte solutions to a model have been made previously by R. H. Stokes and R. A. Robinson[4]. They found that the water 'adsorption isotherm' conforms to a Brunauer–Emmett–Teller type, and an indication was obtained that the hydrogen and lithium ions form a primary solvation shell of four firmly bound water molecules. Their evidence was based on experimental results for molecular water-to-ion ratios of $R > 3:1$ only, and thus could not give detailed information concerning the first three water molecules. Our experiments cover the cases of most monovalent cations for a range down to $R < 1:1$; in some cases hydration results go as low as $R < 0·5:1$. So far, the experimental results have been evaluated for the $H^+$-resin only.

Over this much wider range, the results do not follow a Brunauer–Emmett–Teller isotherm and have to be interpreted as successive addition reactions of the type:

$$\mathrm{H}\cdot(R) + \mathrm{H_2O} \rightleftharpoons [\mathrm{H}\cdot\mathrm{H_2O}]^+ + H_1$$
$$[\mathrm{H}\cdot\mathrm{H_2O}]^+ + \mathrm{H_2O} \rightleftharpoons [\mathrm{H}\cdot 2\mathrm{H_2O}]^+ + H_2,$$
$$\text{etc.},$$

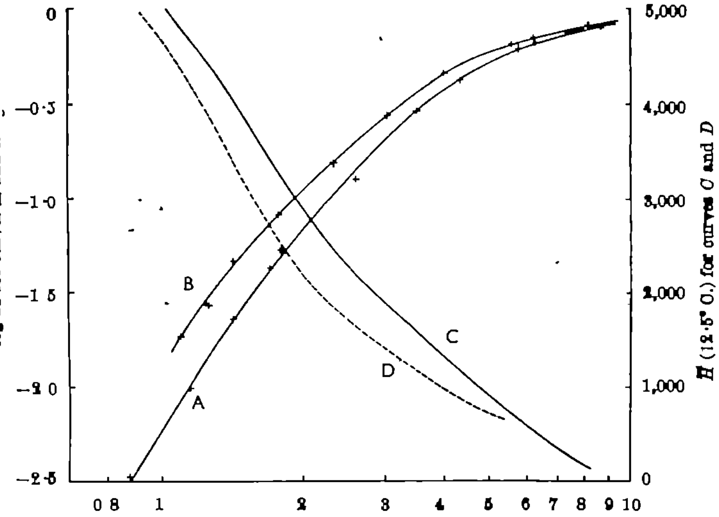
leading to mass law equations:

$$x_1 = K_1 \cdot a_w \cdot x_0$$
$$x_2 = K_2 \cdot a_w \cdot x_1,$$
$$\text{etc.},$$

where $x_0$, $x_1$, $x_2$, etc., are the mol-fractions of ionic species containing 0, 1, 2, etc., molecules of water of hydration, and $H_n$ are the heats of hydration.

The resulting isotherm has the form:

$$\frac{\text{mol H}_2\text{O}}{\text{mol ion}} = R = \frac{K_1 a_w + 2K_1K_2a^2_w + 3K_1K_2K_3a^3_w + \ldots}{1 + K_1a_w + K_1K_2a^2_w + K_1K_2K_3a^3_w + \ldots}$$



Water activities $a_w$ at 0° C. (curve *A*) and 25° C. (curve *B*) and differential heats of hydration $\bar{H}$ at 12·5° C. (curve *C*) as function of the ratio molar water to H-ion, *R*. For comparison, $\bar{H}$ for sulphuric acid solutions (curve *D*)

We obtain for successive water molecules the following values of $K_n$, $\Delta H_n$, $\Delta F_n$ and the entropy,

$$\Delta S_n = \frac{\Delta H_n}{T} + R \ln K_n.$$

CONSTANTS ($K_n$), HEATS OF HYDRATION ($\Delta H_n$), FREE ENERGIES ($\Delta F$) AND ENTROPIES ($\Delta S$) OF SUCCESSIVE HYDRATION STEPS

| $n$ | $K_n$ (273°) | $-\Delta H_n$(285°) $= H_n$ | $\frac{-\Delta F_n (273°)}{RT}$ | $-\Delta S_n$ |
|---|---|---|---|---|
| 1 | 1,050 | >6,000 | 6·96 | >7·0 |
| 2 | 26·0 | ~4,500 | 3·26 | 9·3 |
| 3 | 5·0 | 2,000 | 1·61 | 3·8 |
| 4 | 3·5 | 1,400 | 1·25 | 3·4 |
| 5 | 1·48 | 1,000 | 0·39 | 2·7 |
| 6 | 1·24 | 700 | 0·22 | 2·0 |
| 7 | 1·12 | 400 | 0·11 | 1·2 |
| 8 | 1·06 | 250 | 0·06 | 0·9 |
| 9 | 1·03 | 150 | 0·03 | 0·5 |
| 10 | 1·015 | 100 | 0·015 | 0·3 |
| etc. | →1 | →0 | →0 | →0 |

The large number of constant *K* can be obtained from the single curve *A* quite accurately, as the first four constants each dominates a narrow region only. The knowledge of *K* and of the differential heats $\bar{H}$ (curve *C*) renders possible a calculation of the individual heats of reaction $H_n$ and of the other thermodynamic constants. These results (see table) do not readily give the impression that, in concentrated solutions, four water molecules are firmly associated with the $H^+$ ion. There is a steady decrease both in the heats of reaction and in the free energies, and it requires some arbitrary assumption to differentiate between an 'association' and merely an attractive interaction. One could certainly not speak of an 'association' if the free energy of the reaction $-\Delta F$ is less than $RT$, and this places an upper limit on a hydration number of 4. But $-\Delta F = RT$ corresponds to a very loose association only, and if we stipulate that the free energy should exceed $2RT$ before we consider the association as a moderately firm one, we come to the conclusion that only two water molecules are firmly associated with the $H^+$ ion, and the second one much less firmly than the first.

No doubt it is this uncertainty in deciding the degree of hydration which has led different authors to different conceptions about the hydration of ions according to the methods employed for estimating the 'hydration number'. (For a review on ionic solvation see ref. 5.) The present investigation shows clearly that the concept of a fixed hydration number is too crude, and has to be replaced by a quantitative description of the thermodynamic properties of the individual hydration steps.

It is interesting to speculate on the high values of the entropy changes during the first two steps, from which it appears that these steps are different from subsequent ones. The first water molecule obviously changes the covalently bound hydrogen to the ionized hydronium ion. Presumably the latter is strongly 'ion paired' to the sulphonate group of the resin, and the vigorous electrostatic interaction with the negative ion causes a reduction in the number of possible configurations, which implies an increased entropy difference. Once the second hydration has taken place, the distance of the positive charge from the anion increases, and with it the configuration space and the freedom of rotation of the cation, as is shown by the steady decrease of the entropy differences with every further hydration step.

While some time must necessarily elapse before a detailed account can be given for a larger number of ions, it can already be stated from a cursory study of the experimental results that the same gradual decrease of the energies of hydration applies quite generally to all the alkali ions, to the alkaline earths, as well as to ammonium, silver and mercuric ions, and thus presumably is a characteristic feature of all metal cations.

This communication is published with the permission of the director, Atomic Energy Research Establishment, Harwell. [Nov. 20.

# POTATO BLIGHT FORECASTING AND ITS MECHANIZATION

By DR. JOHN GRAINGER

Department of Plant Pathology, West of Scotland Agricultural College, Auchincruive, Ayr

THE fungus, *Phytophthora infestans*, causing potato blight, the most serious crop disease in Britain, has been shown by Beaumont[1] to begin its attack on the crop some 15–22 days after the occurrence of certain climatic conditions. These are a minimum temperature above 50° F. and a minimum relative humidity greater than 75 per cent, for a continuous period of at least forty-eight hours. During the past nine years I have used this method of forecasting with success in west Scotland when the recording instruments were near the potato crops (Fig. 1). It was, however, found necessary to establish a 'zero time'[2], before which suitable 'Beaumont' periods would not be regarded as valid. Zero time is July 1 for Ayrshire, but is a good deal earlier for the Atlantic islands. It would also be desirable to forecast the pattern and rate of blight development. Fig. 1 shows, however, that the ultimate build-up of this disease is not always closely linked with the occurrence of later 'Beaumont' periods. Experiments in Dumfriesshire and Perthshire suggest, however, that this difficulty may not be so important in practice as it appears in theory. When copper-containing sprays were applied according to blight forecasts in 1949 and 1950, increases in yield reached 28–30 per cent. These figures are high, for the average increase in overall crop cannot have been more than 20 per cent when sprays were given indiscriminately. Forecasts can introduce an important degree of precision into protective spraying, for blight cannot establish itself on foliage already coated with copper-containing sprays.

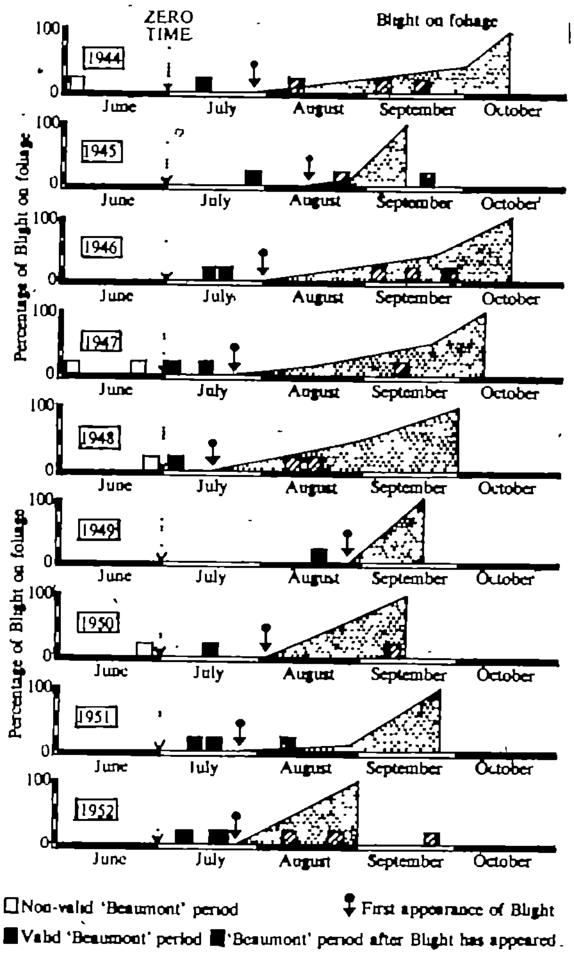

Fig. 1. The occurrence of suitable climatic ('Beaumont') periods and the average development of blight at Auchincruive during 1944–52. Where two valid periods are shown (1946, 1947, 1951 and 1952), the first would have been the operative one

The time of first appearance of blight is also important in another special connexion, namely, the lifting of Epicure 'seed' in Ayrshire. This is usually done in July, during which month the disease appeared in five out of the nine years mentioned in Fig. 1. Even small amounts of blight on the foliage when the crop is lifted infect the tubers, and storage losses are heavy. This type of infection can be prevented by destroying the foliage with sulphuric acid, sodium chlorate or by mechanical means, and waiting a fortnight before lifting. Blight forecasts would advise the farmer as to whether this operation were necessary or not, and here again they would bring precision to control operations.

Forecasts of the first appearance of blight are therefore useful in practice and can be made satisfactorily when recording gear is near a potato crop. It is, however, necessary to extend such a service to cover all potato crops in a given region. A certain measure of success has been obtained over the past three years for wider areas of the west of Scotland, in issuing unofficial forecasts based upon conditions reported by telephone from meteorological stations attached to aerodromes. This has been a most effective co-operative effort, and its only demerit is that the aerodromes are not near the largest potato-growing areas. It becomes increasingly obvious that a greater number of reporting stations is needed in closer relation to the crops if blight forecasting is to become a fully practical proposition.

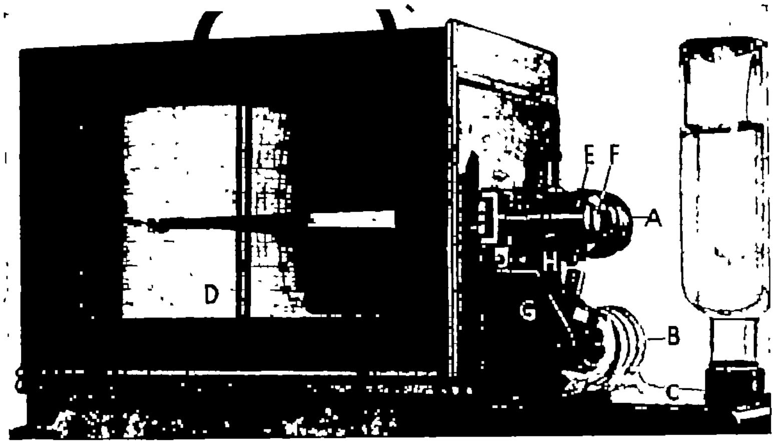

Fig. 2. The 'Auchincruive' self-calculating blight forecast recorder. For explanation of lettering, see text

Temperature can, of course, be recorded adequately by means of a bi-metallic thermograph, and even more accurately with a mercury-in-steel recorder. Relative humidity can be recorded directly by means of a hair hygrograph and by the Gregory humidity recorder; the first is temperamental, the second costly. Duplex wet- and dry-bulb instruments have the demerit that they record only temperature and the depression of the wet bulb, but not the actual percentage relative humidity. Successful forecasts of potato blight have nevertheless been made with such an instrument by Sir James Denby Roberts at Strathallan, Perthshire. Interpretation of the difference between the two traces for a relative humidity of 75 per cent or more is, however, rather difficult, because the depression varies with different temperatures. At 50° F., however, the depression of the wet-bulb reading for this humidity is 3·5° F. If, therefore, the two records are separated by less than this amount for forty-eight hours on end, it is fairly safe to forecast an outbreak of potato blight, provided the dry-bulb temperature is not much above 50° F. Another difficulty is that the two pens are set to record two hours distance apart on the chart, so that considerable skill is required in interpreting this differential comparison. There is thus a need for a forecast recording instrument which could be read and interpreted easily, accurately, and without special skill.

Figs. 2 and 3 show details of an inexpensive, accurate and easily interpreted instrument in which the recording elements are bi-metallic coils. Temperature is recorded in red ink by means of a pen (*E*) driven directly by a dry-bulb coil (*A*). A 'calculator'-pen (*F*), operated in a special manner from a wet-bulb coil (*B*), and marking in green ink, is so calibrated in relation to the temperature-pen that the lines they trace upon a rotating chart drum (*D*) will coincide at the relative humidity of 75 per cent, no matter what the temperature. Calibration of the instrument for this special purpose is done while the 'wet-bulb' coil is dry, when the calculator pen (*F*) is set to record higher than the temperature-pen (*E*). The higher reading is made equal to the depression of the wet-bulb temperature for 75 per cent relative humidity. This depression, and therefore also its corresponding higher reading, vary with different dry-bulb temperatures (see table). The varying higher reading is brought about by means of a cam (*G*) of special shape, driven by the 'wet-bulb' coil, and operating the calculator-pen through a roller movement (*H*) (Fig. 3).

The cam, though made of a single piece of metal, can perhaps best be thought of as having two parts—a basic section and a calculator section, which integrate two kinds of motion. The basic section, if used by itself, would impart a motion to the calculator-pen exactly similar to that of the directly driven temperature-pen for similar conditions around the coils which operate them. Added to the basic section, however, is the wedge-shaped calculator part (shown black in Fig. 3) which is responsible for the varying higher reading mentioned above. The working face of the cam is actually a very slight curve, to reflect the relation (not quite linear) shown in the table, and also the fact that the basic section edge would not be exactly a straight line.

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Dry bulb temperature (°F.) | 20 | 30 | 40 | 50 | 60 | 70 | 80 | 90 |
| Depression of wet-bulb reading for 75 per cent relative humidity in louvre screen (°F.) | 1·5 | 2·2 | 2 8 | 3·5 | 4·2 | 5·0 | 5·8 | 6·6 |

When the instrument is in operation, the wet-bulb coil is kept wet by a muslin sleeve fed by wicks dipping into the water reservoir (*C*). The calculator-pen then reads lower than its calibrated value, and, when the relative humidity is exactly 75 per cent, this depression due to evaporation-cooling of the wet-bulb coil equals the higher setting brought about by the calculator part of the cam. Calculator-pen records (green) are therefore on the same line as the temperature-pen records (red) for the particular relative humidity of 75 per cent, no matter what the dry-bulb temperature may be. Similarly, if the relative humidity is greater than 75 per cent, the

evaporation-cooling of the 'wet-bulb' coil is not sufficient to cause the calculator-pen to fall as far as the temperature record, and green reads above red. Conversely, if green reads below red, the relative humidity is less than 75 per cent. Beaumont's specification[1] of the climatic conditions necessary for a blight forecast are therefore given by the following simple rule:

Green (calculator) on or above red (temperature) and both on or above 50° F. for at least 48 hours on end.

The lag between the two records is reduced to minute proportions by arranging that the two pens only just clear each other. A blight forecaster may be placed within a louvre screen 4 ft. above the ground, or it may be placed in an aspirated screen if an electric fan is available to draw air over the elements. While the self-calculating mechanism as described is here worked from bi-metallic coils, it is equally applicable to mercury-in-steel recorders.

Protective spraying against blight is fully economic in many parts of Britain; but in some areas tuber production is usually complete by the time the disease destroys the foliage, and losses in overall yield are insufficient to balance the expenditure on sprays. Even in such districts, however, any factor which might delay planting in spring retards the growth-cycle, and protective spraying then becomes economic. Blight forecasts are thus of wide application in the improvement of control of this most widespread and severe crop disease.

# X-RAY INACTIVATION OF POLYPLOID *SACCHAROMYCES*

By W. H. LUCKE and A. SARACHEK

Biological Research Laboratory, Southern Illinois University, Carbondale, Illinois

THE recent development by C. C. and G. Lindegren[1] of a family of polyploid yeasts provides the first opportunity of establishing the influence of polyploidy on X-ray inactivation through survival curve analysis. These analyses show that in each cell a single target sensitive to X-rays exists for each chromosome set.

Since polyploidy involves the replication of genetic units, interpretation of the survival curves on a multi-target basis is suggested. The multi-target theory[2] postulates that there is a number of independent targets in the cell, the probability that each target survives a dose $D$ of radiation being

$$P_i = \exp - KD,$$

where $K$ is a constant independent of cell concentration and dose. It is further postulated that there are $n$ sets of these targets (we shall identify $n$ with the number of chromosome sets in the cell), each set containing $m$ different targets (for example, genes or individual chromosomes). The probability $\theta'_i$ that the $i$'th target in one of the $n$ sets is killed is

$$\theta'_i = (1 - \exp - K_i D).$$

The probability that all the $n$ repetitions of the $i$'th target are inactivated is

$$\theta_i = (1 - \exp - K_i D)^n,$$

and the probability that at least one of them survives is

$$S_i = 1 - (1 - \exp - K_i D)^n.$$

Expanding the term in parenthesis by the binomial method, and confining ourselves to doses such that powers of $\exp - K_i D$ higher than the first may be neglected, we have:

$$S_i = 1 - (1 - n \exp - K_i D)$$

$$S_i = n \exp - K_i D.$$

Then the probability that at least one of the $n$ alleles of all the $m$ kinds of targets survives is:

$$S = \prod_{i=1}^{i=m} n \exp - K_i D.$$

Taking the logarithm:

$$\ln S = m \ln n - D \sum_{i=1}^{i=m} K_i. \qquad (1)$$

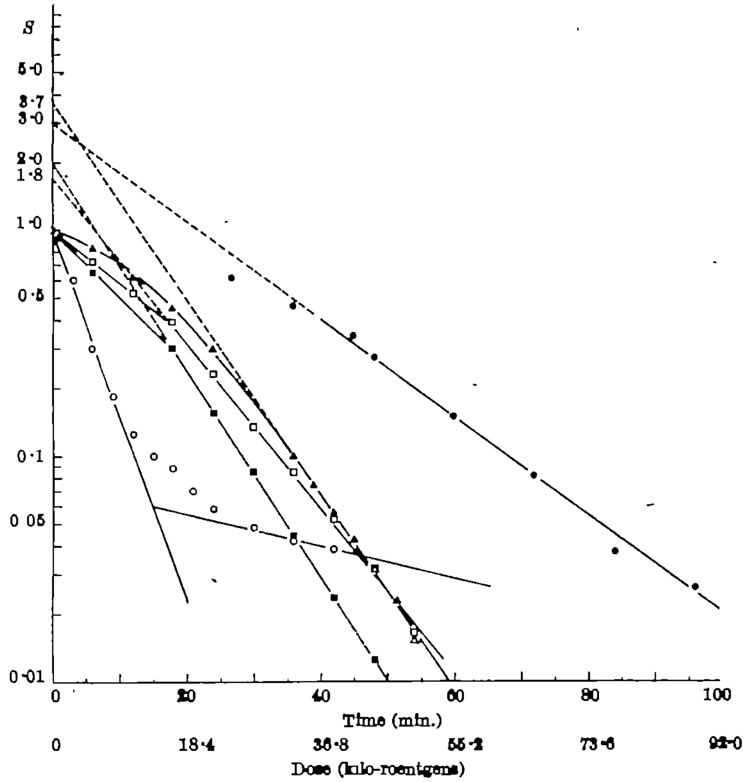
Extrapolation to zero dose gives

$$\ln S = m \ln n.$$

The experimental results are in agreement with equation (1) only for $m = 1$ and $n$ equal to the number of chromosome sets per cell. Under these conditions, all slopes should be equal. While the diploids and the tetraploid have the same slopes, the haploid is about twice as sensitive and the triploid twice as resistant. These figures have been confirmed independently by Pomper and Atwood (personal communication).

A triploid organism was obtained by mating the haploid gamete 13,894 and the diploid gamete 11,296, and a tetraploid was obtained by mating the two diploid gametes 11,294*aa* and 11,296*αα*. Gamete and hybrid clones were grown for 24 hr. on peptone–glucose slants and then refrigerated at 4° C. to serve as stock inocula. Samples of yeast were prepared for irradiation by transferring a heavy loop of cells from a stock inoculum to a 250-ml. flask containing 25 ml. of clarified *V*-8 juice (pH 3·9), a commercial mixture of several vegetable juices. After 44–48 hr. growth on a rotary shaker at 30° C., the cells were harvested, washed twice with 1/15 *M* potassium dihydrogen phosphate and resuspended in 1/15 *M* potassium dihydrogen phosphate to a cell count of approximately $5 \times 10^8$ cells per ml. Under these conditions, the cells were in a nearly uniform physiological state as indicated by the absence of budding and detectable reserves of glycogen and volutin, and the presence of a complement of numerous prominent mitochondria.

A quantity of 30 ml. of the suspension was transferred to a sterile Petri dish and irradiated by X-rays from a tungsten target tube operated at 180 kVp. at a rate of 920 r./min. as measured with a Victoreen 2,500 r. chamber. The total filtration was 3 mm. of aluminium. The suspension was agitated by means of a magnetic stirrer during irradiation. Exposures were made for successive 6-min. intervals. After each exposure a 1-ml. sample was removed, diluted in phosphate and plated in duplicate (controls in quadruplicate) in the following medium: 0·2 per cent Budweiser yeast extract, 0·1 per cent ammonium sulphate, 2·0 per cent dextrose, 0·15 per cent potassium dihydrogen phosphate, 0·05 per cent magnesium sulphate, and 2·0 per cent agar. Percentage survival was determined for each exposure by average macroscopic colony counts after incubation for three days at 30° C.



○—○—, Haploid (13,894), slope = 0·19 ; ■—■—, diploid (11,296), slope = 0·11 ; □—□—, diploid (11,294), slope = 0·086 ; ●—●—, triploid (13,894 × 11,294), slope = 0·050 ; Δ—Δ—, tetraploid (11,294 × 11,296), slope = 0·10

The points for the survival curves shown in the accompanying graph are averages of the survival values for the corresponding dosage as obtained from a number of independent determinations: five for the haploid; six for the diploid 11,294; four for the diploid 11,296; six for the triploid; and six for the tetraploid. Values for the extrapolate and slope were obtained by fitting the straight line portion of the curves by the method of least squares to the equation

$$\ln S = A - KD,$$

where $S$ is the surviving fraction, $A$ is the natural logarithm of the extrapolate, $K$ is the slope and $D$ is the dose expressed in minutes of exposure.

The average survival curves for haploid, diploid, triploid and tetraploid give extrapolates of 1, 2, 3 and 4, respectively (see graph). The extrapolates of individual survival curves were in general well reproducible. The scatter was small, and a good estimate of the extrapolate could be obtained by eye.

The experimental results indicate clearly a one to one correspondence between the degree of polyploidy and the number of targets per cell. It is not possible to state whether the target is a physical part of the chromosome set or is a consequence of the presence of the chromosome set.

An attempt to identify the target leads to the following considerations.

(1) Significant killing by the induction of dominant lethals is eliminated by the occurrence of extrapolates greater than one.

(2) If $m$ is taken to represent the number of genes per chromosome set, the experimentally determined value of unity eliminates recessive lethal mutation as an important aspect of inactivation in the polyploids, although recessive lethal mutation may account for the discrepancy between the haploid slope and the diploid and tetraploid slopes.

(3) If one assumes that all chromosomes have approximately the same sensitivity, and $m$ is taken to represent the number of chromosomes per set, the possibility that inactivation is due to the destruction of homologous chromosomes is eliminated as an important factor, since it is known that there are at least four chromosomes per set in *Saccharomyces*[3].

It may be suggested that the target is a particular chromosome in each set. This hypothesis evidently demands that the chromosome in question be be enormously larger than all the others or much more sensitive. The loss of a very large chromosome, however, would lead to an unbalance which would probably be lethal. The occurrence of an unusually sensitive chromosome seems unlikely in view of the demonstration of the equivalent break sensitivity per unit length in *Drosophila* chromosomes[4].

(4) Inactivation may be due to the destruction of a non-genic target. It is generally observed[5] that inactivated cells undergo several divisions before growth ceases. This indicates that the primary damage is not upon an enzyme or enzyme system but rather upon nuclear entities mediating their production and maintenance. The nucleolus and the central body are two vital extra-chromosomal structures associated with the nucleus. The central body is an unlikely target, since, in general, one exists per nucleus regardless of the degree of polyploidy. In polyploid *Saccharomyces*, it is not known at present whether a single nucleolus exists for each chromosome set or whether the several nucleoli are fused into a single body. Assuming that one nucleolus does exist for each chromosome set, the probability of hitting all nucleoli should not be greater than the probability of hitting homologous chromosomes, since there is no evidence that the nucleoli are significantly larger than the chromosomes.

It is known that radiation causes simultaneous damage to individual genes, enzymes, chromosomes and other organelles. While there is a remote possibility that the total of these damage factors is insignificant in comparison with damage to an as yet unidentified cellular structure, it is more probable that the observed integral extrapolates are expressions under the influence of polyploidy of an unusual inter-relation of these factors.

## Statistical Nature of 'Facilitation' at a Single Nerve–Muscle Junction

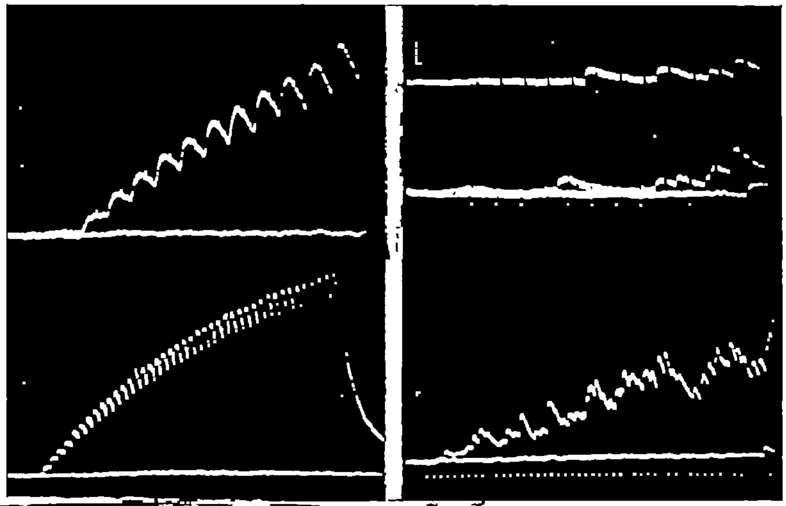
When an impulse arrives at a motor end-plate, it causes acetylcholine to be released at numerous 'key points' and in discrete quanta, each containing a large number of molecules[1]. The discharge of each quantal unit is an all-or-none event, and its success or failure is subject to independent statistical fluctuation. Its chances can be altered by various means, for example, by changing the ionic environment. Even under normal conditions, the probability of an individual 'quantum response' appears to be less than unity; that is, a nerve impulse excites at each junction only a fraction of the whole synaptic population. By lowering the calcium and raising the magnesium concentration, the chance of any one unit responding to a nerve impulse can be reduced to a very low value, and under these conditions, which apply to all the experiments described below, the statistical nature of the transmission process can be demonstrated most effectively.

It has previously been shown that individual quantal units discharge spontaneously, in the absence of nerve impulses[1]. This enables one to measure the mean unit size, and to determine the average number ($m$) of quanta responding to one impulse. Provided $m$ is not too large, it is given simply by the ratio (mean amplitude of response)/(mean amplitude of spontaneous potentials). When $m$ is a small number (the probability of each quantum response being very low), the actual numbers ($x$) in a large series of observations are found to vary at random and to be distributed in accordance with Poisson's law (their relative frequencies being given by $\exp(-m)\, m^x/x!$). The proportion of failures in such a series is $\exp(-m)$; hence the following relation is obtained:

$$\frac{\text{Mean amplitude of response}}{\text{Mean amplitude of spontaneous potentials}} = \ln \frac{\text{No. of nerve impulses}}{\text{No. of failures of end-plate responses}}$$

For example, Fatt and Katz (ref. 1, Fig. 9 and p. 120) described a case of a calcium-deficient end-plate at which 328 nerve impulses elicited 140 end-plate potentials, made up mostly (about a hundred) of single units, the remainder containing two or three quanta. The mean amplitude of 328 responses (including 188 failures) was 0·495 mV.; the mean size of spontaneously occurring potentials (that is, the mean unit size) was 0·875 mV.; hence $m = 0{\cdot}495/0{\cdot}875 = 0{\cdot}57$. From Poisson's law, for $x = 0$, $m = \ln 328/188 = 0{\cdot}56$. Thus, the statistical *average* response in this experiment consisted of less than one quantum per impulse, the observed responses showing a wide, discontinuous variation of amplitudes and a high proportion of total failures.

Some well-known phenomena such as 'facilitation' and 'fatigue', which are generally associated with transmission of impulses across synapses,[2] appear to involve a progressive change in the mean number of quantal units responding to successive impulses. Thus we found with intracellular recording that the second of a pair of nerve impulses, at a time interval of 5–10 msec., produced an increase of 50–80 per cent in the mean size of the end-plate potential. This is the well-known effect of 'facilitation'[3], which has been studied in the past by recording from a whole muscle the average response of hundreds of end-plates, arranged in parallel. We have used a more tedious method of determining the statistical mean, by measuring the average size of hundreds of successive responses from a single end-plate. In this way we found that the increased amplitude of the second end-plate potential is entirely due to an increase of its average quantum content, the second of the two responses following a Poisson series with a significantly lower proportion of failures and larger value of $m$. The chances of excitation of any one unit remained small, but were 50–80 per cent greater for the second of the two nerve impulses. It can be shown that this increased probability does not depend upon there having been a previous response of any unit; and that, in general, the particular units activated by the second impulse are not the same as those responding to the first.



Whole muscle

Single junction

Facilitation of end-plate potentials at the nerve–muscle junction. The records were from nerve–muscle preparations of the frog, blocked by the use of high magnesium (14 m$M$/L.) and low calcium (0·9 m$M$/L.) concentrations, during repetitive stimulation of the nerve at 100 impulses per sec. (in the right part, stimuli are marked by dots). Bottom records were taken on slower time base. Left: Surface recording from a junctional zone of frog's sartorius. Right: Intracellular records from a junction of a muscle fibre of M. ext. l. dig. IV. Note the single spontaneous discharges occurring at the end of the 'base-line' sweeps. Scales: 1 mV.

The statistical nature of 'facilitation' is further shown in the accompanying records. On the left side are records of end-plate potentials obtained with the usual method of surface recording from a whole sartorius muscle. They illustrate that during a rapid firing of nerve impulses, at 10-msec. intervals, successive potentials are not only additive, but grow progressively in amplitude. The growth of the response proceeds smoothly with only slight irregularities, and successive records of this kind show only a minor degree of variation. This is, of course, to be expected, for this method of recording gives us the averaged response from a large number of end-plates. On the right side we have records obtained with an intracellular electrode from a *single* end-plate, presenting a very different picture. The records show the fluctuating character of the response, there being at first a large proportion of failures with occasional 'single-quantum' responses and then an irregular building up of responses interspersed with occasional failures. In the accompanying table, success-and-failure counts of a large number of such records have been summarized. It will be seen that the proportion of failures progressively diminished during the period of stimulation (84 per cent of failures for the first, about 47 per cent for the tenth and 20 per cent for the fortieth impulse), which corresponds to a progressive increase in the Poisson value of *m*. If one measures amplitudes of successive end-plate potentials in the left part of the records, it is found that the tenth response is about five times larger, the fortieth response about ten times larger, than the first. A comparison with the results in the table indicates that this increase, or 'facilitation', must be entirely due to a statistical recruitment of quantal units from a large population of units available at each nerve–muscle junction.

RECRUITMENT OF RESPONSES AT A SINGLE JUNCTION

Summary of seven experiments. Intra-cellular recording from end-plates of frog's muscle, treated with high magnesium and low calcium concentration. Repetitive stimulation of nerve, as in records. Second column shows the total number of impulses in the denominator, and the number of end-plate potentials elicited in the numerator

| Serial No. of nerve impulses (tetani at 100/sec.) | No. of end-plate responses / No. of nerve impulses | Proportion of failures (= exp (− *m*)) | *m* | Facilitation factor ($m_n/m_1$) (mean and S.E.) |
|---|---|---|---|---|
| $N_1$ | $\frac{111}{710}$ | 0·84 | 0·18 | 1·0 |
| $N_{6-15}$ | $\frac{858}{1,615}$ | 0·47 | 0·83 | 4·7 ± 0 45 |
| $N_{16-35}$ | $\frac{799}{1,140}$ | 0·3 | 1 28 | 7·1 ± 0·66 |
| $N_{36-45}$ | $\frac{886}{1,105}$ | 0·2 | 1·72 | 9 9 ± 1·25 |

The basis of the quantal mechanism is unknown: it may be that each unit of discharge starts with the activation of a single 'key molecule', opening a local 'gate' in the nerve membrane and releasing a flood of acetylcholine ions. The activation of such key—or 'carrier'—molecules may result from spontaneous thermal agitation, and the effect of a nerve impulse may be to lower their activation threshold, thus causing a synchronized opening of many local 'gates' and a flooding of the whole end-plate with the transmitter substance. But while there is little doubt about the quantal nature of the end-plate response, and about some of the statistical rules by which it is governed, there is no evidence available at present to support speculations about the details of the quantal mechanism.

## Radio Echoes observed during Auroræ and Terrestrial Magnetic Storms using 35 and 74 Mc./s. Waves Simultaneously

In an undisturbed and extended ionosphere, the maximum value of the frequency of radio waves which can be reflected by regular refraction processes is determined by the maximum electron density of the layer. The maximum value of the critical frequency at vertical incidence seldom exceeds 15 Mc./s.

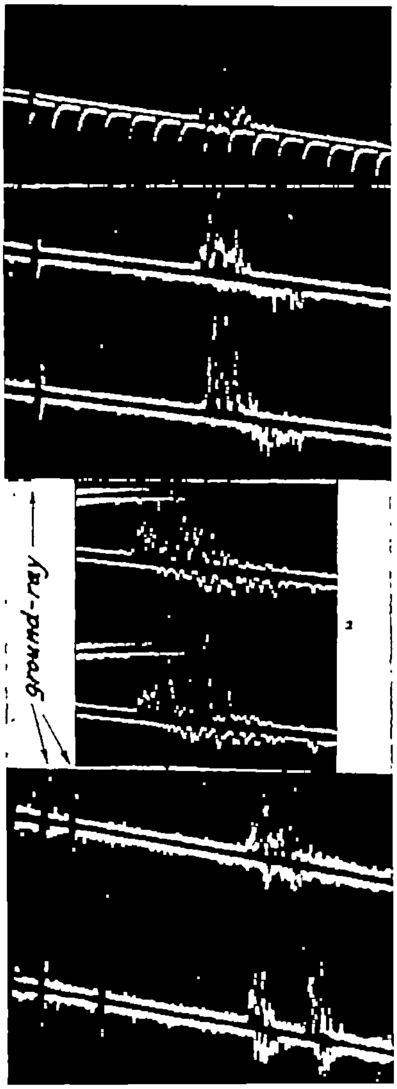
During recent years, considerable attention has been paid to scattering processes of radio waves in the ionosphere. In an inhomogeneous ionosphere it should be possible to get scattered reflexions from 'blobs' or stratifications in the electron densities using waves in the very high frequency band. Scattered reflexions in this have been observed in a number of cases[1]; and in all of them the reflexions have been associated with the appearance in the sky of definite auroral forms.

In the following, the results of observations during auroral displays and terrestrial magnetic storms made at Tromsö (near the auroral zone) and at Kjeller (near Oslo) will be given. The recording equipment consisted of two pulse transmitters on 35 and 74 Mc./s., both having a common pulse-modulator and high-tension supply. The energies and the shape of the two pulses sent out simultaneously could therefore be made identical (peak-power 25 kW. and repetition frequency 50 c./s.). Two geometrically identical six- or three-element yagis, with a half-width of the lobe of 65° directed towards the north, were used as antennæ; the elevation of the beam could be varied. The echoes were displayed on a double-beam cathode-ray tube with common sweep.

The echo records at Tromsö showed that echoes on 35 Mc./s. appeared regularly during auroral displays, and in a number of cases also on 74 Mc./s. A closer study of the echoes led to the conclusion that in the cases under discussion the echoes could not be explained by direct scatter from the ionosphere, but by reflexion of backwards scatter from land or sea via the lower part of the *E*-layer (the $E_s$-layer) the ionization of which increases strongly during auroral and terrestrial magnetic storms. Our explanation of the very high frequency echoes observed is therefore in opposition to the common assumption of direct and primary scatter from the auroral forms or inhomogeneities in the ionosphere. The arguments supporting our explanation of the mechanism of reflexion are as follows.

There is no correlation between the ranges of the echoes and the distances to auroræ simultaneously appearing. Even the most brilliant auroral forms appearing at distances from 80 km. (in the zenith) and up to 400–500 km. (low in the north) do not give the slightest traces of echoes appearing when the antennæ are directed against the auroral forms. But at the same time, echoes are observed with ranges of 600–1,800 km. when the antennæ were directed horizontally against the north. It has been assumed[2] that reflexions from an aurora mainly occur when the waves are incident normally to the direction of the earth's magnetic field. In this case we should get no reflexions from the auroræ observed visually in Tromsö. But it is difficult to imagine that this condition is so strictly maintained that the most violent aurora at 80 km. distance does not give the slightest trace of echoes.

In all cases the echoes on 35 Mc./s. showed a noticeably smaller range than the echoes on 74 Mc./s.



Simultaneous echoes on 35 and 74 Mc./s. recorded on a double-beam cathode-ray tube. The upper trace shows 35 and the lower 74 Mc./s., 50 c./s. repetition frequency, recorded on moving film; the distance between the pips represents 100 km. (1) Different reflexion distances for 35 and 74 Mc./s. scatter; (2) lack of correlation between the subsequent sweeps as well as between the 35 and 74 Mc./s. patterns, recorded on an expanded time-scale; (3) double-pulse is used with changing time-separation, and correlation between the echo patterns is obtained when the time separation is of the order of less than 2 millisec.

This difference in range varied and usually amounted to more than 100 km. (see Fig. 1).

The echoes were spread out in time corresponding to a difference in the range from 100 km. and up to several hundreds of kilometres.

Echoes on 35 Mc./s. were considerably stronger than on 74 Mc./s., and echoes on the higher frequency usually appeared during the stronger phases of the terrestrial magnetic storms.

Polarization tests were made on 35 Mc./s. The waves were sent out vertically polarized and received on vertical and horizontal polarized yagis simultaneously through two separate channels. Generally, there was no difference in field-strength of the echoes through the two channels.

With a repetition frequency of 50 c./s., there was no correlation between the echo pattern of subsequent sweeps. In Fig. 2, where the echo patterns are recorded on a fast-moving film, the subsequent echo patterns have changed completely. In this case an increased sweep velocity has been used for analysing the echo pattern.

There is no correlation between the structure of the echo patterns on 35 and 74 Mc./s.

By using double pulses, the distance between the pulses being made variable, it could be shown that a correlation between the echo structures appeared when the time interval between the two pulses was less than about 2 millisec. This corresponds to a ray-path of 300 km., in which case the two echo patterns appeared well separated in time. This is evident from Fig. 3.

There is a difference in character of the echo patterns on 35 and 74 Mc./s. The echoes on 35 Mc./s. exhibited usually a well-defined leading edge with maximum amplitude just after the leading edge. On 74 Mc./s. there was often no leading edge; the echo amplitude increased continuously from zero, and the maximum amplitude was usually considerably displaced towards greater distances.

During one severe terrestrial magnetic storm on November 28, 1952, pulses sent out from Kjeller were received in Tromsö, where they appeared undisturbed, having the same width as the pulses transmitted. During this severe storm the auroral zone had apparently been displaced towards the south and the $E_s$-layer acted as a mirror-like reflexion surface. The echoes received back at Kjeller, however, showed the usual distortion.

The characteristics of the echoes summarized above cannot be explained by primary scatter from the ionosphere, whereas the assumption of backwards-scatter from land or sea via the lower part of the ionosphere, the $E_s$-layer, fits in with the characteristics of the echoes described above.

A full account of the observations will be given in *J. Atmo. Terr. Phys.*

## Fractionation of Isotopes by Distillation of some Organic Substances

We have found that the distillation of chloroform, carbon tetrachloride, methyl alcohol and benzene leads, surprisingly enough, in all four cases to an enrichment of carbon-13 in the distillate, whereas the other heavy isotopes, such as chlorine-37 and oxygen-18, are enriched in the still pot.

The distillations were carried out in empty tube columns, consisting of a great number of narrow, unpacked parallel working tubes with individual reflux[1]. All distillations were carried out at 34·6° C. using very high reflux ratios. Samples withdrawn from the head and the bottom of the column were treated in the manner described below to yield gaseous products, such as carbon dioxide and hydrogen chloride, suitable for mass spectrometric analysis. The isotopic abundance ratios were determined by means of a 60° double-collector mass spectrometer (Consolidated–Nier 21–201).

According to the theories of Kuhn[2] and Westhaver[3], the height equivalent to a theoretical plate of empty tube columns may be reduced to a theoretical minimum given by the radius of the tubes (for example, 0·2 cm.), and distillations in which such high separation efficiencies have been very nearly obtained have been reported by Kuhn and Ryffel[4]. The hold-up, and accordingly the time required until equilibrium conditions are obtained, is very small in such columns. The number of effective theoretical plates $n$ of the columns at infinite reflux ratio can be calculated from the length $L$ and the radius $r$ of the tubes, from the average vapour speed $\bar{u}$ and from the diffusion constant $D$ in the vapour according to the relation[2]:

$$n = \frac{4LD}{r^2 . \bar{u}} . \qquad (1)$$

Expressions for $n$ in the case of finite reflux ratios have been derived recently[5].

From the number of theoretical plates $n$ and from the isotopic fractionation, the relative difference in vapour pressure of the isotopic species is calculated according to the following relation derived from the Fenske equation:

$$\frac{p_1 - p_2}{p_2} = \left(\frac{R_B}{R_D}\right)^{1/n} - 1, \qquad (2)$$

where $p_1$ and $p_2$ are the vapour pressures at the distillation temperature (34·6° C.) of the pure light and the corresponding pure heavy isotopic molecules respectively, $R_B$ and $R_D$ represent the isotopic abundance ratios in the still pot and distillate, respectively, of the heavy to the light atom under consideration, and $n$ is the number of effective theoretical plates.

The difference in boiling temperatures $\Delta T$ of the two isotopic species is approximately obtained from (2) and from the vapour pressure equation using Trouton's rule:

$$\Delta T = T_1 - T_2 = -\frac{T_1^2}{10{\cdot}7\, T_b n} \ln \frac{R_B}{R_D}, \qquad (3)$$

where $T_1$ and $T_2$ are the absolute boiling temperatures of the pure light and the pure heavy substance respectively at the pressure at which the distillation is performed; $T_b$ is the normal boiling temperature.

If there are several isotopic atoms of the same element in the molecule, for example, chlorine in the case of carbon tetrachloride, the indexes 1 and 2 in equations (2) and (3) can be shown to refer to two isotopic molecules of neighbouring molecular weight, for example, $C^{35}Cl_2{}^{37}Cl_2$ and $C^{35}Cl^{37}Cl_3$ or $C^{35}Cl^{37}Cl_3$ and $C^{37}Cl_4$. This holds in any event, whether exchange of the isotopic atoms between the molecules in the distillation process is possible or not, provided only that the difference in boiling temperatures between all pairs of neighbouring molecules is the same.

*Chloroform.* Already in 1945 we found that the distillation of chloroform in an empty tube column leads to an enrichment of chlorine-35 in the distillate, the ratio $^{37}Cl/^{35}Cl$ being shifted by amounts up to 12 per cent. The isotope analysis was performed at that time by density measurements, by a spectroscopic method[6], and by using the nuclear reaction $^{37}Cl(n,\gamma)^{38}Cl$[7]. We now find that the agreement with the mass spectrometric ratio determination as performed recently on samples which had been kept from this distillation is satisfactory.

Gaseous hydrogen chloride and carbon dioxide were obtained for mass spectrometric analysis by the reaction of chloroform with potassium hydroxide. The potassium chloride and formate obtained were, after oxidation of the formate to carbonate, treated with acid, liberating hydrogen chloride and carbon dioxide.

From the results of the isotope analysis and from the number of theoretical plates $n$ used in the distillation, the following results were obtained from equations (2) and (3):

Table 1

| $n = 610$ | Isotopic fractionation of chloroform with respect to: Carbon | Chlorine |
|---|---|---|
| $R_B/R_D$ | 0·62 | 1·06 |
| $\frac{p_1 - p_2}{p_2}$ | $-8\times10^{-4}$ | $+10^{-4}$ |
| $T_1 - T_2$ | + 0·02° C. | − 0·003° C. |

Purification of the chloroform for the density determination was carried out as follows. After shaking with concentrated sulphuric acid, the chloroform was distilled off and condensed under vacuum on tetra-salicylide with which, according to Anschütz[8], it forms a very specific addition compound. Upon heating this compound, some low-boiling impurities come off first and are rejected, the pure chloroform being obtained upon further heating. This procedure was repeated several times until no change in density (using the float method) could be observed. To apply the spectroscopic method referred to above, the chlorine must be present in the form of $HgCl_2$, which was obtained from the chloroform by alkaline hydrolysis, precipitation of the chlorine ions as silver chloride and fusing the dried silver chloride precipitate with mercuric sulphate. The mercuric chloride formed according to the reaction $2AgCl + HgSO_4 \rightarrow Ag_2SO_4 + HgCl_2$ is separated from the reaction mixture by repeated sublimation.

*Carbon tetrachloride.* Attempts to fractionate the chlorine isotopes by high-efficiency distillation of carbon tetrachloride have been reported by Grimm[9] and by Rank and Kargarise[10]. These authors, using the density method of isotopic analysis, did not, however, find any fractionation.

In our case the distillation was carried out in a column with $n = 80$, and the carbon tetrachloride samples were treated for analysis by passing a stream of hydrogen through them and burning the mixture containing some 10 per cent carbon tetrachloride in oxygen. The hydrogen chloride and carbon dioxide thus formed were trapped in an excess of barium hydroxide solution and separated as chloride and carbonate. Pure hydrogen chloride and carbon dioxide were liberated by acid treatment. The following results[1] were obtained.

Table 2

| $n = 80$ | Isotopic fractionation of carbon tetrachloride with respect to: Carbon | Chlorine |
|---|---|---|
| $R_B/R_D$ | 0·90 | 1·003 |
| $\frac{p_1 - p_2}{p_2}$ | $-1{\cdot}3 \times 10^{-3}$ | $+3 \times 10^{-5}$ |
| $T_1 - T_2$ | + 0·033° C. | − 0·001° C. |

The above results indicate that, while there is only a very slight enrichment of chlorine-35 in the distillate, the concentration of carbon-13 is increased considerably. The calculation shows that the resulting effects on the density are of the same order of magnitude but of opposite sign. This would account for the lack of any effect reported in previous studies[9,10].

*Methyl alcohol.* An enrichment of oxygen-18 in the residue of a methyl alcohol distillation has been reported by Roberts and Urey[11]. In our study, methyl alcohol was distilled in a column with 140 theoretical plates. The samples for investigation were burnt in oxygen of known isotopic composition and the gases thus formed were collected. Water and carbon dioxide were brought to exchange equilibrium at room temperature, and the $^{18}O/^{16}O$ ratio in the methyl alcohol was calculated from that in the carbon dioxide and from that in the oxygen entering and leaving. The results are shown in Table 3. An enrichment of $CH_3OD$ in the still pot was found qualitatively.

Table 3

| $n = 140$ | Isotopic fractionation of methyl alcohol with respect to : Carbon | Oxygen |
|---|---|---|
| $R_B/R_D$ | 0·97 | 1·50 |
| $\frac{p_1 - p_2}{p_2}$ | $-2 \times 10^{-4}$ | $3 \times 10^{-3}$ |
| $T_1 - T_2$ | + 0·0055° C. | − 0·07° C. |

*Benzene.* Pure benzene was distilled in a column with $n = 80$. The samples were burnt in a hydrogen–oxygen flame and the carbon dioxide thus formed was trapped in barium hydroxide solution. The carbonate was decomposed with acid to yield pure carbon dioxide, for which $^{13}C/^{12}C$ analysis led to the following results :

$$R_B/R_D = 0{\cdot}98, \quad \frac{p_1 - p_2}{p_2} = -2{\cdot}5 \times 10^{-4},$$

$$T_1 - T_2 = +\ 0{\cdot}006^\circ\ C.$$

The results obtained by the distillation of chloroform, carbon tetrachloride and methyl alcohol indicate the possible existence of a general rule stating that, in isotopic molecules having a central atom, the molecular variety containing the heavier isotope of the central atom will exhibit a somewhat higher vapour pressure than the variety containing the lighter isotope as central atom. Results in agreement with this rule have been found recently by Green and Martin[12] in the case of boron trichloride.

We wish to thank Dr. P. Massini for carrying out some of the distillations, Dr. K. Wieland (Zurich) for the spectroscopic isotope analysis of chlorine, and Dr. F. Alder, of the Physics Department, Basel, for the isotope analysis of chlorine by nuclear reaction. This work was supported by grants from the Eidgenössische Volkswirtschaftsstiftung, the Ciba-Stiftung and the Freiwillige akademische Gesellschaft.

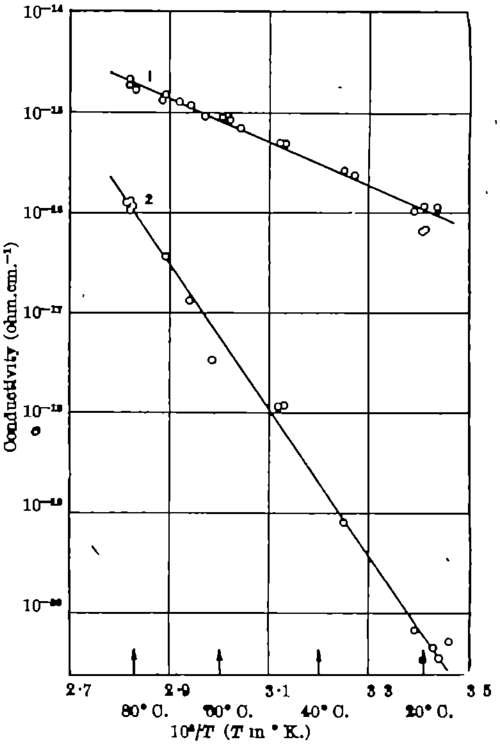
## Effect of Temperature on the Conductivity induced in Insulators by X-Rays

STUDIES of the induced conductivity in insulators due to X-rays[1] are difficult owing to the extremely low values to be measured, and hitherto have been made primarily with condenser chambers[2]. These allow only the after-effect of the radiation to be determined. If measurements of conductivity during exposure are to be made, the apparatus must admit no air gap at any point between the insulator under test and the electrometer, and in addition the volume of insulator irradiated must be as large as possible, so as to give sufficient current for measurement.

These difficulties were overcome in the present tests by using a length of 6 metres of polythene-insulated cable coiled into a flat spiral and connecting the end of the cable, outside the room, to a source of voltage and a D.C. amplifier. The coil was enclosed in a 'Perspex' box through which heated air could be passed to control the temperature. The object was to determine the temperature coefficient both of irradiated and unirradiated material, and hence the energy-levels of conduction bands under the two conditions from the general relationship,

$$\sigma = \sigma_0 \exp(-\ W/kT).$$

The X-rays were generated at 220 kV. (2·5 mm. copper half-value layer) with a dose-rate of about 8 r./min. The conductivity was measured every minute after commencement of exposure, and the present figures relate to the equilibrium conductivity which is attained after about ten minutes of irradiation. Graph 1 shows the relationship between log (conductivity) and $1/T^\circ$ K. for the range 20–80° C. The straight line confirms the above law for this material. The slope gives $W = 0{\cdot}42$ eV.



(1) Irradiated with X-rays ; (2) unirradiated

The corresponding graph (2) for the unirradiated material is also a straight line, which has a steeper slope, giving $W = 1{\cdot}5$ eV.

It will be observed that in either case the effect of temperature is large. Under irradiation at room temperature, the conductivity increases by 5·6 per cent per deg. C. The corresponding increase for unirradiated material is 19 per cent per deg. C. It is clear from these results that no accurate studies of induced conductivity can be made without very careful temperature control[3]. If such control is applied, however, consistent results are obtained which can be interpreted in terms of energy-level distributions, and the behaviour of the material is not unlike that of crystalline materials[4].

## Degradation of Methionine by Hydrogen Peroxide

I have been searching for an appropriate method of oxidizing methionine from biological materials with hydrogen peroxide in order to be able to detect the amino-acid as its sulphone on paper chromatograms as a discrete spot. During the course of this work, it has been found that the heating of methionine in solutions of hydrogen peroxide leads to the formation of several ninhydrin-reacting substances, some of which are of biological interest as possible intermediates in the metabolism of methionine in animal organisms. In the present communication the procedures employed to effect the degradation of methionine, and the results obtained in a preliminary identification of the substances thus produced, are described.

To study the degradation of methionine in its various stages, 0·05 m$M$ aliquots of DL-methionine were added to 0·2–10·0 ml. of hydrogen peroxide solution, the concentration of which was 0·1 m$M$ per ml., thus producing mixtures with ratios of methionine to hydrogen peroxide varying from 1 : 0·4 to 1 : 20. These mixtures were sealed in glass tubes and heated in a boiling water-bath for 12 hr. The solutions were then removed from the glass tubes, evaporated to dryness under reduced pressure, and the residues dissolved in 0·5 ml. distilled water. Those reaction mixtures which became strongly acid, as the result of the formation of sulphuric acid, were neutralized with a solution of barium hydroxide, and the resulting precipitate was removed before evaporation. Similar experiments were also carried out starting with methionine sulphoxide and methionine sulphone.

One- and two-dimensional chromatograms were run according to the method described by Williams and Kirby[1]. A phenol – water (80 : 20, v/v) system and a collidine – pyridine – water (150 : 20 : 100, v/v) system were used as developing solvents. For two-dimensional chromatography, 1–10 μl. portions of the solutions of reaction products prepared as described above were used.

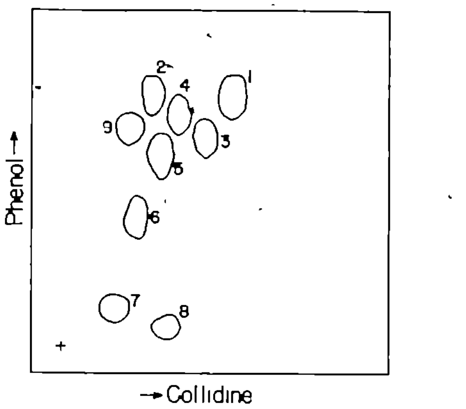

Diagram of two-dimensional chromatogram of ninhydrin-reacting substances derived from methionine by oxidation with hydrogen peroxide. 1, methionine; 2, methionine sulphoxide; 3, methionine sulphone; 4, α-aminobutyric acid; 5, alanine or homoserine, or both; 6, glycine, 7, aspartic acid; 8, cysteic acid, 0, unknown

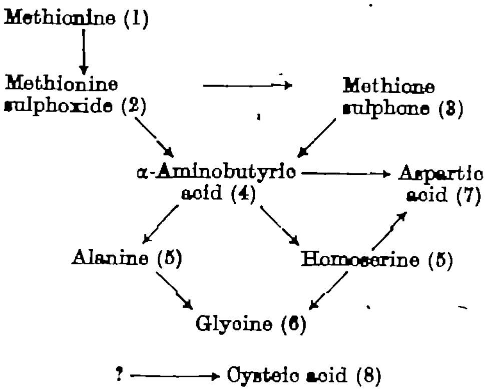
The accompanying diagram is a composite one of the spots appearing on the two-dimensional chromatograms, and it shows all the ninhydrin-reacting substances derived from methionine by oxidation with hydrogen peroxide. All these spots on the paper chromatograms showed the typical ninhydrin reaction of amino-acids, and none of them survived the distinctive test for α-amino-acids reported by Crumpler and Dent[2]. Identification of these substances was carried out only by means of paper chromatography.

Neither of the solvents used in this study, nor their combination in the two-dimensional technique, could separate alanine and homoserine completely. In another experiment, solutions of alanine and hydrogen peroxide were heated in the presence of sulphuric acid. The chromatographic analysis of the product of this reaction could support the interpretation that glycine was formed from alanine. Since, as mentioned above, sulphuric acid is formed when methionine is heated in a solution of hydrogen peroxide, it might be suggested that spot 5 is alanine, and glycine (spot 6) is derived from alanine. However, it is possible that spot 5 is homoserine, because homoserine was found to give rise to glycine and aspartic acid under the same conditions. It was also found that under the same conditions α-aminobutyric acid can yield glycine, aspartic acid and spot 5. Therefore, spot 5 can be interpreted as being either alanine or homoserine; or it may represent both amino-acids.

All the spots shown in the diagram, except that of methionine, were observed in the reaction mixtures when the experiment began with methionine sulphoxide. When methionine sulphone was used instead, spots 4 and 5 could not be detected; and, of course, spots corresponding to methionine and methionine sulphoxide were absent in this case. The reason for the absence of spots 4 and 5 may be that methionine sulphone is very stable under the conditions of this experiment; α-aminobutyric acid and the substance represented by spot 5, which are less stable in comparison to methionine sulphone, are rapidly converted to other oxidation products.

Cysteic acid might be produced by a reaction between sulphuric acid and a 3-carbon moiety, though no proof of this has been obtained. The nature of spot 9 is unknown.



Possible pathway of degradation of methionine by hydrogen peroxide

A possible pathway for the degradation of methionine under the experimental conditions employed in this work is shown in the diagram. That α-aminobutyric acid can be derived from methionine through its sulphoxide, and very possibly also through its sulphone, is most interesting.

Thanks are due to Drs. T. Minoshima and H. Nakamura for their interest in this work.

## Crystalline Trypsin

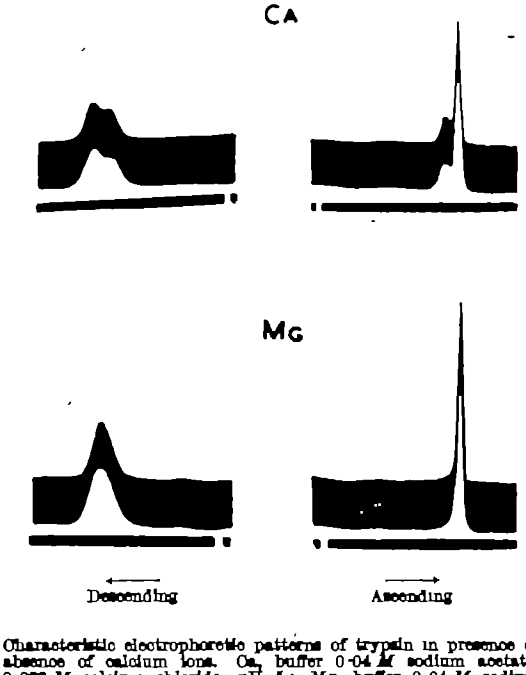
INVESTIGATIONS carried out during the past two years have revealed the existence of a complex interaction between trypsin and certain specific divalent ions, particularly calcium ions. These relations manifest themselves in various ways and have been studied in arbitrarily differentiated *p*H-stability zones of trypsin.

In the region of its optimum proteolytic activity, between *p*H 7 and 9, calcium and manganese ions were the only ones in a comprehensive list of ions tested which stabilize trypsin solutions[1,2]. By means of electrophoretic analyses performed in this *p*H region, it could be demonstrated that the calcium effect is due to a diminishing of the rate of self-digestion, and it was concluded that calcium causes a shift in the equilibrium existing between the native and denatured forms of the enzyme towards the former. This work also resulted in a redetermination of the isoelectric point of the enzyme, which lies in the neighbourhood of *p*H 10·8, and was amplified by a partial determination of the amino-acid composition[1]. The same ions, as well as cadmium and cobalt ions, were found to augment slightly the activity of the enzyme[3], while an investigation over the whole *p*H range has shown that the higher activity can be ascribed to the increased concentration of the active form of the enzyme[4]. On the other hand, calcium has shown itself to be without specific protective effect in inactivation of the enzyme brought about by ionizing radiation[5].

The maximum stability zone of the enzyme is at about *p*H 2·3. Ultracentrifugal sedimentation patterns are characteristic of a homogeneous protein having a sedimentation constant $s_{20,w}$ of 2·5 *S* [6] or 2·4 *S* [7]. On prolonged standing at the acid side of this *p*H, some faster sedimenting components appear as a result of the aggregation of the slowly denaturing enzyme which is not complicated by proteolysis. The sedimentation behaviour at *p*H 8 is quite similar to that observed at acid *p*H with the exception that, on prolonged standing, some slower sedimenting products of the self-digestion appear. The presence of either of these breakdown products or of the aggregated enzyme in acid solutions does not influence the sedimentation-rate of the remaining unaltered trypsin[7].

It is between the above two extreme *p*H regions that a number of other significant manifestations of the effect of calcium can be observed. It was reported that the sedimentation constant increases in this range, the maximum aggregation being at about *p*H 5 [6]. Our investigations resulted in the observation that this aggregation is strongly dependent on temperature, the sedimentation constant decreasing to about a normal value at 30° C. The presence of 0·05 *M* calcium chloride completely prevents this aggregation[7]. More direct evidence of an interaction between calcium and trypsin in this *p*H range was obtained by the study of the dissociation curves of trypsin. Calcium ions, in contrast to magnesium ions, give rise to a shift in the titration curves of the enzyme in the regions of the dissociation of carboxylic groups towards more acid *p*H values. The formation of the complex thus demonstrated causes the lowering of the dissociation constants of the carboxylic groups[4].

It was therefore to be expected that the decrease in net charge of the enzyme, due to the formation of the complex with calcium, could be evidenced by electrophoretic analysis. The characteristic patterns



Characteristic electrophoretic patterns of trypsin in presence or absence of calcium ions. Ca, buffer 0·04 *M* sodium acetate, 0·033 *M* calcium chloride, *p*H 5; Mg, buffer 0·04 *M* sodium acetate, 0·033 *M* magnesium chloride, *p*H 5 of trypsin at $pH$ 5, in 0·04 $M$ acetate buffer, in the presence of 0·033 $M$ magnesium or calcium chloride, all other conditions being equal, are shown in the accompanying diagram. It can readily be seen that, in the absence of calcium, trypsin presents an electrophoretic pattern characteristic of a homogeneous compound, the presence of calcium ions causing the separation of the moving boundary into two well-defined peaks. Of the two boundaries, the larger one moves with a mobility characteristic of trypsin in the absence of calcium, and the smaller boundary moves at a slightly slower rate. At a lower concentration of calcium ions, the appearance of the secondary peak is not so well defined; but further increase in the calcium ion concentration does not change the electrophoretic patterns. It is characteristic that identical patterns are also observed in the presence of manganese as well as cadmium ions which have already been mentioned as increasing the activity of the enzyme[2]. Cobalt, magnesium and barium ions, listed in order of decreasing effect, also increase the activity of trypsin, but to a lesser degree than calcium, manganese or cadmium ions, which are equivalent in their action. Under our experimental conditions, neither of the first three ions causes the characteristic change in the electrophoretic pattern; together with all other ions tested, they give rise to electrophoretically homogeneous patterns of trypsin. Nevertheless, there is no doubt that the two effects are due to the same cause.

After a prolonged electrophoretic separation, it was possible to obtain small samples of the faster and slower components. In four independent analyses, the tryptic activity of both components was found to be proportional to the concentration of the protein as determined by ultra-violet absorption at 280 mμ. Crystalline trypsin was also digested at $pH$ 8 in the presence and absence of calcium, and aliquot samples were analysed electrophoretically at 24-hr. intervals, the electrophoretic analyses having been carried out in the presence of calcium under the conditions already mentioned. It was thus possible to determine the rate of digestion of both components in the presence or absence of calcium. In both instances t was found that the ratio of the areas of the two components did not change in the course of the self-digestion, although the overall rate of digestion was considerably diminished by the presence of calcium. It appears, therefore, that crystalline trypsin is electrophoretically heterogeneous, containing two components both of which possess a similar tryptic activity and rate of self-digestion and both of which are subject to protection by calcium ions. An ndication of this heterogeneity has already been reported[1].

Another example of an electrophoretically heterogeneous protein in which all components have similar biological activity was found in ovomucoid[8], the antitryptic factor of egg-white. The aggregaion observed in the absence of calcium by ultracentrifugal analysis is viewed as resulting from a reversible interaction of the two components. As a consequence, only one peak appears in electrophoretic analysis, moving with the weighted average of the mobilities of the two components. Calcium, combining with the carboxyl groups, prevents this aggregation, resulting in a normal sedimentation behaviour and appearance of the two electrophoretic components.

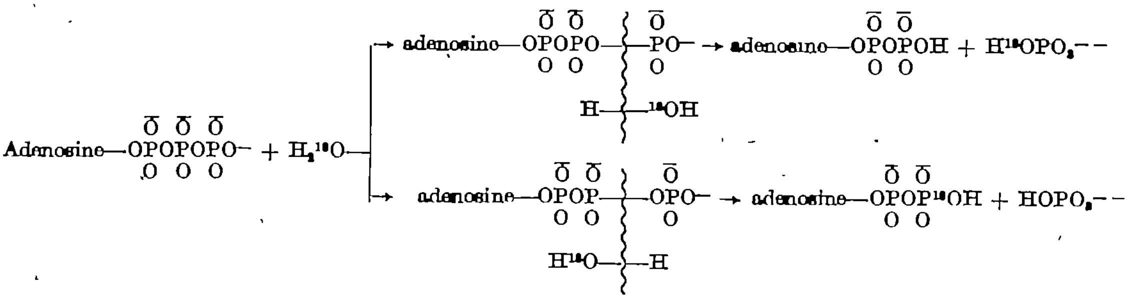
## Mechanism of Hydrolysis of Adenosine Triphosphate catalysed by Lobster Muscle

IN previous publications[1] evidence has been presented for the occurrence of displacement mechanisms in a wide variety of enzymatic reactions to which those of adenosine triphosphate are closely analogous. Assuming that the adenosine triphosphate reactions proceed by the same mechanisms, it can be deduced from the nature of the products that the adenosine triphosphate can undergo nucleophilic attack at any of its three phosphorus atoms. As examples, the Lohmann reaction with creatine[2] must involve attack at the terminal phosphorus atom, the coenzyme A reaction of Lipmann *et al.*[3] must involve attack at the middle phosphorus atom and the Kornberg reaction with nicotinamide mononucleotide[4] must involve attack at the innermost phosphorus atom. If the adenosine triphosphate is hydrolysed by an adenosine triphosphatase in ordinary water to adenosine diphosphate and inorganic phosphate, the pathway is not obvious, since attack at either the terminal phosphorus atom or the middle phosphorus atom would give the same products. This ambiguity can be avoided, however, by using $H_2{}^{18}O$, in which case the alternatives are clearly distinguishable (cf. reaction 1). The study of the mechanism of adenosine triphosphate hydrolysis in muscle was therefore performed in a medium of $H_2{}^{18}O$ and the products were analysed for their content of oxygen-18.

Lobster muscle strips (25 gm.) were thoroughly washed with potassium chloride solution and then incubated with $H_2{}^{18}O$ (100 c.c., 1·3 atom per cent excess) for 1 hr. until equilibration between the water of the medium and that of the muscle strips had occurred. Solid adenosine triphosphate (2·55 m$M$) was then added, and the solution was stirred for 30 min. until 77 per cent of the adenosine triphosphate had been hydrolysed to the diphosphate and inorganic phosphate. After removing the muscle strips, the phosphate compounds were precipitated as the barium salts and separated on ion exchange columns following the procedure of Cohn and Carter[5]. Operations subsequent to the enzymatic hydrolysis were performed in the cold under conditions which were shown to prevent appreciable decomposition of the labile compounds. To ensure purity of the separated products, only the middle fractions of each well-isolated peak were used in the subsequent analyses.



$$\text{Adenosine—}\overset{\bar{O}\,\bar{O}\,\bar{O}}{\underset{O\;O\;O}{OPOPOPO^-}} + H_2{}^{18}O \rightarrow \text{adenosine—}\overset{\bar{O}\,\bar{O}}{\underset{O\;O}{OPOPO}}\overset{\bar{O}}{\underset{O}{—PO^-}},\ H—{}^{18}OH \rightarrow \text{adenosine—}\overset{\bar{O}\,\bar{O}}{\underset{O\;O}{OPOPOH}} + H^{18}OPO_3{}^{--} \quad (1a)$$

$$\rightarrow \text{adenosine—}\overset{\bar{O}\,\bar{O}}{\underset{O\;O}{OPOP}}\overset{\bar{O}}{\underset{O}{—OPO^-}},\ H^{18}O—H \rightarrow \text{adenosine—}\overset{\bar{O}\,\bar{O}}{\underset{O\;O}{OPOP^{18}OH}} + HOPO_3{}^{--} \quad (1b)$$

Determination of oxygen-18 showed that the terminal group of the adenosine triphosphate, the terminal group of the diphosphate, and the inorganic phosphate contained 0·0514, 0·00513 and 0·815 atom per cent excess per atom of oxygen, respectively.

Control experiments were performed in which (*a*) the medium contained ordinary water, and inorganic phosphate labelled with phosphorus-32 was added with the adenosine triphosphate, and (*b*) the medium contained $H_2{}^{18}O$ but only inorganic phosphate was added to the solution. In experiment (*a*), the hydrolysis was 64 per cent complete, and the adenosine tri- and di-phosphate and the muscle strips contained 0·11, 0·016 and 4·3 per cent of the total counts added, respectively. In experiment (*b*) the inorganic phosphate had 0·026 atom per cent excess.

From the small oxygen-18 content of the adenosine diphosphate, it is clear that the mechanism of hydrolysis catalysed by the muscle phosphatase(s) involves a nucleophilic displacement on the terminal phosphorus atom. The oxygen-18 present in the unhydrolysed adenosine triphosphate results predominantly from exchange with, or synthesis from, the intracellular inorganic phosphate, since the quantity of labelled element determined agrees with that calculated from the phosphorus-32 control experiment if appropriate corrections for diffusion-rates and extent of hydrolysis are made. The oxygen-18 content in the adenosine diphosphate is likewise correlated with its phosphorus-32 content in the control experiment.

The oxygen-18 content of the inorganic phosphate per atom of oxygen would be one-quarter that of the medium from the direct hydrolysis of adenosine triphosphate (cf. reaction 1 *a*). The fact that it is considerably higher than this shows that the muscle preparation catalyses a net transfer of oxygen between inorganic phosphate and water. This is further confirmed by the observed exchange in control experiment (*b*). The total exchange is less in the latter case than in the hydrolysis experiment presumably because the inorganic phosphate is released inside the cell in the hydrolysis experiment, whereas in control (*b*) the inorganic phosphate is initially extracellular. From the measured metabolic-rates in the lobster muscle preparation it can be calculated that the increased oxygen-18 content of the inorganic phosphate is caused only in minor part by the recycling of inorganic phosphate through adenosine triphosphate, and must be due in large part to a more direct exchange reaction. A somewhat similar exchange which does not go through high-energy phosphate has been observed in mitochondrial preparations by M. Cohn[6]. Since it has been shown that the exchange with inorganic phosphate can be catalysed by a single enzyme[1b], it is conceivable that the reaction in the muscle may also be caused by an individual enzyme which catalyses a nucleophilic attack on phosphorus.

This investigation was carried out under the auspices of the U.S. Atomic Energy Commission.

## Possible Role of Proteolytic Enzymes in Protein Synthesis

BERGMANN[1] has proposed that proteolytic enzymes mediate in the biological synthesis of proteins from amino-acids. The 400–4,000[2] or more[3] calories per mole required for peptide bond formation from *free* amino-acids can, however, be provided only when synthesis is coupled with an energy-yielding reaction[4]. To accommodate this energy requirement, Brenner, Hanes, Fruton and co-workers[4-6] have demonstrated that a variety of proteolytic enzymes catalyse a reaction of esters, amides, or peptides (including the naturally occurring peptide, glutathione) with amines or amino-acids in which new amides or peptides are formed. The enzymes show their usual specificity; that is, they synthesize only those peptide bonds that they also hydrolyse. The energy requirement is me by the initial ester, amide or peptide linkage which is split, for there is presumably very little difference in energy between the bond destroyed and that formed. These workers have shown beyond doub that some or perhaps most proteolytic enzymes can catalyse polypeptide synthesis from amino-acids providing there is an independent method o 'energizing' the amino-acid (ester, amide, peptide etc.). From there it is possible to speculate that in a similar way these proteolytic enzymes play a part in normal protein synthesis.

As a test of this hypothesis, Hendler and Greenberg[5] have recently studied the metabolism of labelled γ-glutamyl-glycine; but they found that this particula compound is not significantly involved in any o several living systems that incorporate amino-acid into proteins. The evidence presented here also doe not appear to be consistent with the hypothesis outlined above.

We have described techniques for measuring the rate of incorporation of various radioactive amino-acids such as glycine and alanine into the protein of tissue slices, and have outlined reasons for believing that this is closely related to biological protein synthesis[6]. Using these techniques, we have incubated α-aminobutyric acid-1-$^{14}C$ with rat liver slices. When the protein is isolated and the amino-acids separated by chromatography[7], we find that the labelled aminobutyric acid has been incorporated into the protein to only a very slight extent, if at all. The ratio of alanine incorporation to aminobutyric acid incorporation is at least one hundred and fifty to one, and may be much higher when improved chromatographic techniques are used. We find, however, that these two amino-acids are oxidized to the α-keto-acids and to carbon-14 dioxide at a similar rate by the liver slices, and that there is, at the end of the experiment, about the same intracellular level of aminobutyric acid as of alanine. Clearly, we have shown that aminobutyric acid is as actively carried into the cell as alanine, and as effectively utilized in some reactions, but that those enzymes which are responsible for protein synthesis in the living cell are sufficiently specific to reject aminobutyric acid, the next higher homologue of alanine and the next lower homologue of valine.

Such specificity is striking and is in agreement with the concept, which has gained so much support from the recent work of Sanger and Tuppy[8] on the structure of insulin, that a protein is a specific compound with a perfectly definite amino-acid sequence. One may ask whether every protein of the cell has such a definite structure.

Are the proteolytic enzymes of the cell sufficiently specific to reject α-aminobutyric acid 150 to 1 with respect to alanine? It is inherent in the theory of catalysis that the catalyst should not affect the equilibrium of a reaction; hence that it must accelerate the forward and reverse reactions equally. The catalytic activity of a given enzyme in synthesizing aminobutyrylglycine can be roughly estimated by measuring the rate of hydrolysis of the dipeptide. To be precise, the rate of hydrolysis corresponds to the rate of synthesis from two free amino-acids, the rate of ethanolysis corresponds to synthesis from the ethyl ester and one free amino-acid, etc.

In all cases that have been reported, aminobutyric acid-peptides are split at rates comparable with the corresponding alanyl-peptides. However, the enzymes used were extracellular. Smith and Polglase[9] found that α-aminobutyric acid amide was split by leucine amino-peptidase from intestinal mucosa at a rate between alanyl- and leucyl-amide. We have measured the rates of hydrolysis of alanyl-, aminobutyryl-, and leucyl-glycine by the proteolytic enzymes of freshly homogenized rat liver, that is, precisely the tissue which rejects aminobutyric acid for protein synthesis. The accompanying results show that aminobutyrylglycine is split by these intracellular enzymes at about the same rate as alanylglycine under these conditions.

While this may be taken as evidence against the participation of proteolytic enzymes in normal protein synthesis, it is not conclusive. A wide range of aminobutyric acid peptides should be tested. It is also possible that the great degree of specificity of protein synthesis is found in the enzymes acting on the larger peptides. We feel, however, that unless an enzyme system does discriminate against aminobutyric acid or an aminobutyric acid peptide, the system being studied should not be considered as part of the mechanism of biological synthesis of protein.

HYDROLYSIS OF PEPTIDES

| Substrate | Concentration | % Hydrolysis |
|---|---|---|
| DL-Alanylglycine | 0·16 *M*<br>0·08 *M* | 41<br>85 |
| DL-α-Aminobutyrylglycine | 0·17 *M*<br>0·09 *M* | 37<br>63 |
| DL-Leucylglycine | 0·12 *M*<br>0·06 *M* | 10<br>16 |

1 gm. of fresh rat liver homogenized in 10 c.c. 0·1 *M* phosphate buffer, *p*H 8·2; suspension centrifuged, supernatant diluted 1 : 40 with same buffer, and used as source of enzyme. Incubation mixture: 1 c.c. of enzyme solution, 1 c.c. of peptide solution, 0·01 c.c. of toluene. Temp. 37°.

Incubation time, 6 hr. Hydrolysis determined by ninhydrin method (ref. 10). Per cent calculated for L-isomer only; hydrolysis of D-isomer considered to be negligible.

This investigation was supported by grants-in-aid from the American Cancer Society, Inc., and the United States Atomic Energy Commission. We thank Drs. Joseph C. Aub, Elizabeth B. Keller and Paul C. Zamecnik for helpful suggestions and criticisms.

## A Disulphide Interchange Reaction

IN experiments designed to determine the position of the —S—S— bonds in insulin, cystine peptides were separated from a partial acid hydrolysate, and their structures determined after oxidation to the corresponding cysteic acid peptides. It was found that many more cystine peptides were present than could be accounted for by any one unique structure for the insulin molecule, and it seemed likely that a transfer reaction of the type:

$$R^1\text{—S—S—}R^2 + R^3\text{—S—S—}R^4 \rightleftharpoons R^1\text{—S—S—}R^3 + R^2\text{—S—S—}R^4$$

had taken place during the hydrolytic treatment, leading to a random rearrangement of the —S—S— bonds. That such a reaction can take place was illustrated by the following model experiment, in which *mono*-2 : 4-dinitrophenyl-cystine is formed from a mixture of cystine and *bis*-2 : 4-dinitrophenyl-cystine.

1 mgm. *bis*-2 : 4-dinitrophenyl-cystine and 10 mgm. cystine were incubated with 2 ml. of 12 $N$ hydrochloric acid. After 24 hr. at 37°, 5 ml. water and 10 ml. ether were added and the mixture shaken. Nearly all the yellow colour was found in the aqueous layer, indicating the presence of *mono*-2 : 4-dinitrophenyl-cystine. In a control experiment without cystine, all the colour which was due to *bis*-compound was in the ether layer. The reaction-rate is rapid in strongly acid or in neutral solution and is minimal in dilute acid (about 0·1 $N$ hydrochloric acid). This probably explains the fact that insulin is inactivated more readily by heating in neutral than in dilute acid solution[1], if the rearrangement of the —S—S— bridges is assumed to cause inactivation.

The mechanism of the reaction is not clear at present and is under investigation. It may involve the intermediate formation of an —SH compound by reduction or hydrolysis, in which case the actual rearrangement would be brought about by the reaction :

$$—R^1—\mathrm{SH} + R^2—\mathrm{S}—\mathrm{S}—R^3 \rightleftarrows R^2—\mathrm{SH} + R^1—\mathrm{S}—\mathrm{S}—R^3.$$

In this case the $R^2$—SH formed would be available to react with a further disulphide, so that only a catalytic amount of an —SH compound could bring about considerable rearrangement[2].

I wish to thank Dr. G. Weber for some valuable advice in connexion with this work.

## Structural Features of Antitumorigenic Corticoids

THE antifibromatogenic potency of deoxycorticosterone—prevention of œstrogen-induced abdominal fibroids—diminishes through the substitution $O{=}C_{11}$ (Kendall's compound *A*) and especially through OH−−$C_{17}$ (Reichstein's compound *S*)[1]. The antifibromatogenic potency of cortisone, which differs from deoxycorticosterone by both these substitutions, is also strikingly diminished ; there were fibroids even with as much as 1,000 $\mu$gm. of cortisone acetate per day. But, on the other hand, there apparently was some antifibromatogenic activity of compound *F*, or 17-hydroxy-corticosterone (OH−−$C_{17}$ and OH—$C_{11}$); we had thus to raise the question of a 'protective' action of OH—$C_{11}$ against OH−−$C_{17}$. However, in view of the variations of the fibrous tumoral effect met with in similar experiments, and especially in view of the small number of experiments performed with compound *F*, the conclusion as to the supposed 'protective' action of OH—$C_{11}$ against OH−−$C_{17}$ remained doubtful[1]. In the meantime, we have been able to settle this question in what seems to be a definite manner, thanks to the kindness of Messrs. Merck and Co., who put at our disposal the necessary quantities of compound *F* acetate.

Ten animals (castrated female guinea pigs) were used in the experiment, which lasted 91–92 days. An average of 81 $\mu$gm. of œstradiol per day was absorbed from subcutaneously implanted tablets ; 268–447 $\mu$gm. (average 350) of compound *F* acetate was absorbed per day from two tablets (a new implantation six weeks after the first one). There were fibroids in nine out of ten animals ; average fibrotumoral effect, 5·2 ; average weight of uterus 4·6 gm. The quantities of compound *F* were indeed smaller than in some animals of the former series, in which there apparently was prevention ; but there is the fact that fibroids were present in the new series, even with quantities as large as 350–447 $\mu$gm. of compound *F* acetate per day. It is thus evident that OH—$C_{11}$ does not afford 'protection' against OH−−$C_{17}$, by which antifibromatogenic potency is so greatly diminished (compound *S*).

Although we must drop our original concept of 'protection' by OH—$C_{11}$ against OH−−$C_{17}$ with reference to antifibromatogenic corticoids, it is very remarkable that the same concept seems to be valid with reference to the inhibition of the growth of the chick embryo, as evidenced by certain findings of Stock[2]. The effective growth-inhibiting dose of deoxycorticosterone is 250 $\mu$gm. ; that of compound *S* (OH−−$C_{17}$) is as high as 5,000 $\mu$gm.; but the effective dose of compound *F* (OH−−$C_{17}$ and OH—$C_{11}$) is only 20 $\mu$gm.

Attention may also be directed to a comparative discussion of the structural features of antifibromatogenic and antilymphomatogenic corticoids[3].

## Multi-spots in Paper Chromatograms

DURING investigations on the synthesis of nucleotides in this laboratory, extensive use has been made of the paper chromatography of phosphorus-containing compounds. In the early experiments it was observed that in a descending pyridine – ethyl acetate – water system, disodium hydrogen phosphate gave two clear spots of approximately equal intensity with $R_F$ 0·17 and 0·55 on spraying with molybdate reagent[1]. Identical spots were obtained with sodium or potassium mono- or di-hydrogen phosphates, whereas ammonium phosphate and free orthophosphoric acid gave only the faster-running spot. Trisodium phosphate showed largely the slower spot with some trailing. (These $R_F$ values are quoted to give an indication of the positions of the spots. The temperature was not strictly controlled. Other experiments showed the effect was not due to complexes with pyridine as the same 'double-spot' phenomenon occurred in a butanol – water system. By buffering the phosphates with acid and alkali it was found that the number of spots depended on the $p$H of the solution in which the phosphate was applied to the paper. Potassium dihydrogen phosphate below $pH$ 3 gave only the faster running spot; between $pH$ 3 and $pH$ 9, both spots at $R_F$ 0·17 and 0·55 were in evidence, but by $pH$ 10 (caustic soda added) only the slower spot appeared. Above $pH$ 12 only a spot at $R_F$ 0·05 was obtained with a horseshoe appearance (compare Paterson and Reincke[2]).

Further experiments were carried out using phosphoric acid containing phosphorus-32. When used in tracer amounts, it was found that the counts from the radioactive phosphorus agreed in position with the colours from the spraying. As an indication of the discreteness of the spots, it was found that a count of 6,000 a minute at the site of the spots fell between them to less than 100. When, however, phosphoric acid having a specific activity of 1 mC./ml. was diluted with water and adjusted in $pH$ with suitable acetate buffers, it was found that in this case, with the quantity of phosphate infinitesimal compared to the usual concentration of 0·04 $M$, there were no double spots'. Instead, at $pH$ 2·5 there was one site of counts at $R_F$ 0·55, whereas at both $pH$ 4 and $pH$ 5·5 counts were only at $R_F$ 0·17. As before, at $pH$ 14 the phosphate concentration was at $R_F$ 0·05.

It is considered from these results that it is possible that the spot at $R_F$ 0·55 is given by the $H_2PO_4^-$ ion, that at $R_F$ 0·17 by the $HPO_4^{--}$ ion and that at $R_F$ 0·05 by the $PO_4^{---}$ ion.

The mechanism of the separation of these spots is difficult to visualize. If the equilibrium $H_2PO_4^- \rightleftharpoons HPO_4^{--} + H^+$ were disturbed by the separation of the faster-running $H_2PO_4^-$, then the equilibrium should readjust itself and cause extensive trailing. One explanation is that the time of proton transfer in this equilibrium is slow. An experiment was devised that could to some extent check this. $H_3{}^{32}PO_4$ was mixed with $Na_2H^{31}PO_4$ and the mixture out on a chromatogram. If the $H_3{}^{32}PO_4$ (which existed as $H_2{}^{32}PO_4^-$) did not exchange with the $H^{31}PO_4^{--}$, then no counts should be found at the slower-running spot. When this experiment was carried out, counts were found at both sites. This means that the time required for equilibrium must be shorter than that required for the spots to separate on paper.

There have been other reports of double spots in paper chromatographic experiments[1,2]; but in these cases it is possible that they were due to interference of un-ionized compounds with inorganic ions or to impurities in the paper. All the experiments described above were conducted on No. 1 Whatman paper which had been washed with 2 $N$ acetic acid, and it is not considered possible for this multiplicity to be caused by contamination.

Evidence that the $pH$ of the solution in which the specimen is applied to the paper affects the $R_F$ of the resultant spot has been amply demonstrated in the case of the amino-acids[3], and it has been suggested that the separation of lysine into different ionic species may be due to association with phenol in the developing solvent[4].

Whatever the cause, this double-spot phenomenon does mean that, where polyvalent ions are encountered, it is possible that multi-spots may be obtained.

Two examples encountered subsequent to the work with inorganic orthophosphate may serve as an indication of the care necessary in the interpretation of experiments that have been followed by paper chromatography. Pure 2′ : 3′-*iso*propylidene adenosine-5′-dibenzyl phosphate[5] was hydrogenated in an effort to obtain 2′ : 3′-*iso*propylidene adenosine-5′-phosphate. The final product could not be crystallized but showed on chromatography in an ascending butanol – acetic acid solvent two spots of $R_F$ 0·56 and 0·64. On acid treatment to remove the acetone group, only adenylic acid remained, and since it was not a case of one of these spots being either adenylic acid or a monobenzyl ester of it or the acetone derivative, it is possible that they are both derived from the divalent 2′ : 3′-*iso*propylidene adenosine-5′-phosphate. The other example was that of adenosine diphosphate run in a descending butanol – acetic acid solvent giving one spot when in low concentration, and this splitting into two spots when the concentration was increased.

I would like to thank Prof. A. R. Todd and Dr. G. W. Kenner for much advice during these investigations.

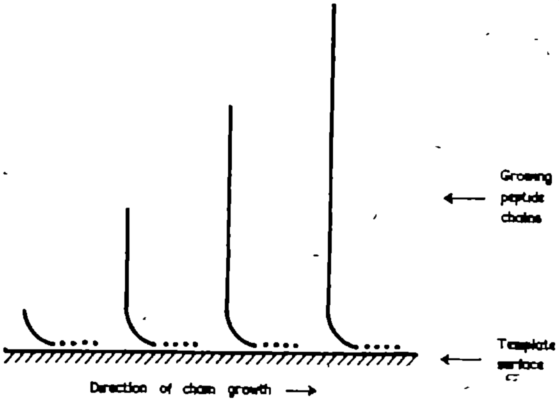
## The Template Theory and the Role of Transpeptidation in Protein Biosynthesis

THE synthesis of protein occurs without detectable evidence of free peptide intermediates. This fact, and the specificity of proteins, have been explained by the so-called 'template theory', in which it is assumed that the amino-acids are laid down in their correct order on a template (? consisting of nucleic acid) with subsequent bond formation and separation from the template[1]. Recent work has shown that transpeptidation occurs with peptides in artificial systems[2], and evidence has been sought for the participation of transpeptidation in protein synthesis. In these experiments protein synthesis has been brought about in the presence of isotopically labelled amino-acid. The resultant protein is degraded, the appropriate amino-acid isolated from two different parts of the chain and the specific activities compared. It is assumed that if the template theory is correct, all amino-acids must be laid down on the template effectively simultaneously, so that differences in activity of the same amino-acid residue in different parts of the chain are evidence for transpeptidation[3]. We wish to show that this assumption is not necessarily justifiable.

Energy considerations make it most unlikely that a complete protein molecule is formed on a template surface and afterwards separates as a whole from the surface. It is much more probable that amino-acids become attached to the surface of the template, and that as the amino-acid residues link together, the growing peptide chain 'peels off' behind the zone of formation of peptide bonds, as has been postulated in the recent theory of Dounce[4]. In such a case the protein does not finally separate from the surface until it is complete (so that no intermediate steps are observed); but only a small region is attached to the template at any time. Moreover, after a 'wave' of biosynthesis has passed down the template surface, the latter can be reactivated, further replacement by



amino-acids can occur, and a further 'wave' of biosynthesis may pass along. Many peptide chains at different stages of growth may thus be attached to the template at the same time, as is suggested in the diagram.

If a template were to carry simultaneously twenty growing protein molecules in different stages of development, the actual time of biosynthesis of each molecule would be twenty times the apparent time per molecule. Thus the time of biosynthesis of a protein may be much longer than is generally supposed. In the biosynthetic experiments, the amino-acids are drawn from a pool with which the labelled amino-acid may or may not have become equilibrated. In any normal biological system, the specific activity of the pool changes with time, and to show that differential degrees of labelling of the same amino-acid residue in different parts of a protein chain are due to transpeptidation, it must be shown that the difference is too great to be accounted for by changes with time in the activity of the pool. Conclusions are therefore not valid without evidence of the time of biosynthesis of a single molecule of the particular protein being investigated. No such evidence appears to be available, so that transpeptidation cannot yet be said to have been demonstrated in protein biosynthesis.

## Quantitative Estimation of the Total Solids in Fresh Whole Milk by Oxidimetry

Since the major organic constituents of milk, with the possible exception of the fat, carry readily oxidizable groups, it should be possible to measure their amount by oxidimetry. Although the fat itself may not be readily oxidizable, it may possibly be measured indirectly by means of the substances associated with it in the fat phase and which are probably present in proportion to the amount of fat. Thus it would appear reasonable to believe that an oxidimetric method could be devised for measuring the total solids of milk. Such a test could be carried out much more rapidly and simply than by the methods usually employed.

After several trials using ceric sulphate in $N$ sulphuric acid and ferrous-*o*-phenanthroline as oxidant and indicator respectively, the following method was tentatively adopted as a means of testing the theory.

The milk was secured from the weigh-tank and 10 ml. was diluted to 100 ml. with distilled water and well mixed. 10 ml. of the diluted milk was transferred to a casserole containing 20 ml. of distilled water, two drops of ferrous-*o*-phenanthroline were added and the mixture titrated against 0·01 $N$ ceric sulphate in $N$ sulphuric acid until the orange colour was discharged. The titration was continued after the lapse of one minute, and the total number of millilitres of ceric sulphate used was taken as the titre value of the milk. (It was found that titrating at a constant rate yielded closer agreement between duplicates.)

Thirty-one samples of herd milk representing milk from five different breeds of cows were tested by this method, and the results compared with the value for total solids obtained with the A.O.A.C. gravimetric method ("Methods of Analysis", A.O.A.C., 7th edit., 1950).

The results yielded a coefficient of correlation between titre values and total solids values of $r = 0·912$ with a standard error of estimate of ± 0·238 per cent total solids. It is noteworthy that the error between duplicate titrations was approximately ± 0·05 ml., causing a final error of ± 0·22 per cent in the total solids, which is in good agreement with the standard error of estimate.

While the above method in its present form may not serve as a practical means for measuring the total solids in milk, it does justify the view that such measurements may be done by oxidimetry, and should serve as a starting point in the search for a rapid and accurate method.

## A New Linkage in Tobacco

In about seven genetic linkages so far found in *Nicotiana* species, only one concerns *tabacum* and another *rustica*. The rest of the five linkages were discovered in interspecific crosses involving *N. tabacum* *N. langsdorffii* and *N. sanderæ*[1]. Kelaney[2] found a linkage between a gene *Br* for broad-constricted leaf with the gene *Pk* for carmine-pink flowers with a 7·5 per cent crossing-over. Boortzev[3] mentions linkage of 4·35 per cent between seed colour and compact habit in *N. rustica*. Clausen and Cameron[4] have isolated twenty-four monosomics of tobacco and were able to locate cytologically eighteen genes for sixteen characters in nine chromosomes by crossing the monosomics with a standard tobacco type. In six of the chromosomes identified, more than one gene has been found, but the authors do not mention the position of genes and distances between them.

We present here a new case of linkage between a gene for petiolate condition and absence of auricle of leaf found in a cross made during 1949–50 between Lanka and Yellow-Special varieties of *N. tabacum*

| Exp. 16 6 per cent cross-over | 16·84 | 1·91 | 1·91 | 4·34 | 25 | 0·1508 | 0·90–0·95 |
| Exp. 19·988 per cent cross-over | 16·5012 | 2·2482 | 2·2482 | 4·002 | 24·99 | 0·4030 | 0 80 |
| Back-cross | | | | | | | |
| Obs. | 16 | 5 | 4 | 18 | 43 | | |
| Exp. 1 . 1 : 1 . 1 | 10·75 | 10·75 | 10·75 | 10·75 | 43 | 12·5263 | < 0·01 |
| Exp. 20·93 per cent cross-over | 17·00 | 4·50 | 4·50 | 17·00 | 43 | 0·2288 | 0 80–0·90 |
| Exp. 19·988 per cent cross-over | 17 2026 | 4·2974 | 4·2974 | 17·2026 | 43 | 0·2402 | 0·80–0 90 |

Lanka is an indigenous variety grown exclusively in the islands formed by the Godavari River ; it has a petiolate leaf with no auricle, but very slight growth of tissue in its place. Yellow-Special is a flue-cured type originally obtained from America, and has sessile leaves with large auricles which extend down the stem. The $F_1$ was petiolate and developed only a thin fringe at the leaf base, which was slightly more prominent than in Lanka, indicating that petiolate condition and absence of auricle are dominant characters. The $F_2$ generation consisted of eighteen petiolate and seven sessile plants. For the other character also there happened to be eighteen non-auricled and seven auricled plants. Thus both the characters showed monogenic inheritance. The back-cross ($F_1$ × Yellow-Special) confirmed the $F_2$ behaviour. The gene pairs are designated *Pt*-*pt* and $Au_2$-$au_2$.

When the $F_2$ and back-cross data were considered for joint segregation of the two characters, in both cases there was significant disagreement between the observed and the expected frequencies on the basis of independent assortment of the two genes. Determination of linkage intensities gave 16·6 per cent cross-over for $F_2$ and 20·93 per cent cross-over for back-cross. A pooled estimate[5] from the two populations gave 19·988 ± 5·49 per cent cross-over. The relevant data are presented in the accompanying table.

From these results it can be concluded that the gene *Pt*, for petiolate condition of leaf, is linked at about 20 morgans with the dominant gene $Au_2$ for absence of auricle.

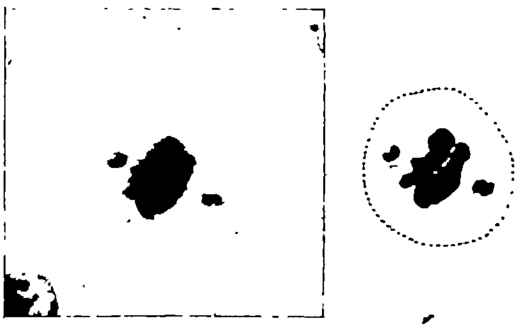
## Production of 'Three-Group Metaphases' in the Bone-Marrow of the Golden Hamster

A FEW years ago, a new type of chemically produced abnormality of mitosis, henceforth termed 'three-group metaphase', appearing shortly after an injection of hydroquinone, in the intestinal germinative cells of the mouse, was reported in *Nature*[1]. Later, the rat also proved itself to be a convenient material, while the guinea pig, the chick and chick fibroblast cultures were not responsive as regards this effect[2].

With the opportunity of using new techniques and material, the same phenomenon has been observed not only in the intestine but also in the bone marrow of the golden hamster in the first six hours following an intraperitoneal injection of hydroquinone, in doses varying from 0·150 mgm. to 0·200 mgm./gm. These mitoses, characterized by an apparently normally formed metaphase plate and by aberrant chromatic bodies localized at the poles of the spindle, appear with high incidence in the cells of the granular series, whereas the erythroblast divisions remain apparently unaffected. Almost at the same time, pycnotic nuclei become more and more numerous and the number of white cell mitoses gradually decreases, so that after twenty-four hours mature polynuclears are relatively more abundant.

With this possibility of further investigation into the mechanisms of this peculiar lesion, it has now become evident that the hypothesis of chromosome breakage put forward in our first publication cannot be maintained for mammals, even though it has been demonstrated to hold true in plant cells[3]. In fact, the polar Feulgen-positive bodies can be ascertained to represent well-formed and defined chromosomes, with their longitudinal fissuring very often apparent. Our further suggestion[4], that these aberrant chromosomes were retained in the centrosome region and did not undergo their pre-metaphase migration, gains strong support from the evidence of morphological features of some of the altered metaphases. Indeed, this explanation is in accordance with the finding of numerous asymmetrical figures—metaphase plate and one polar group—which cannot be attributed to an early anaphasic migration of the smaller chromosomes after their normal division.

Furthermore, seeking for intermediary figures, a few later stages have been discovered, which, obviously independent of chromosome fragmentation, strongly enhance the hypothesis of the possible completion of these mitoses. They consist of early anaphases with the metaphase plate clearly split in two. At this stage, the aberrant chromosomes are still visible



Bone marrow of golden hamster 1½ hr. after an injection of 0·150 mgm./gm. hydroquinone. Feulgen-squash preparation. Myelocyte 'three-group metaphase' showing early anaphase movements, the two central groups of chromosomes being already clearly distinct at the poles of the spindle (see photograph). Later, they can no longer be identified as they probably become hidden among the normal and rapidly migrating chromosomes. After six hours, when the destructive action is most evident, some of the 'three-group metaphases' have been observed to participate in the pycnotic effect. The three separate groups sometimes undergo chromatic condensation, giving rise to another peculiar image which could be termed 'three-group pycnosis'. While they are not visible twenty-four hours after the injection, there is still no evidence that all the 'three-group metaphases' are destroyed in this manner.

More detailed observations on the action of hydroquinone and related substances on the bone-marrow and other tissues of the mouse, the rat and the rabbit, and on the cellular changes causing this new type of pathological mitosis, will be published shortly elsewhere.

These experiments were started during a short stay at the Chester Beatty Institute, London, and I wish to express my thanks especially to Dr. P. C. Koller.

## A New Method in Staining Bacteria on Microscope Slides

A NEW method of providing dyes for some of the commoner staining procedures has been developed and tested. A small volume of the required dye solution is prepared according to the appropriate formula. The fluid is placed in a large dish, and rounds of No. 4 Whatman filter paper are soaked in it. After a few seconds the paper is removed by means of flat forceps and hung over a glass rod to dry. The dye-paper is then cut into suitable 'chips'—papers 1½ in. long by ½ in. wide are found to give good results. One round of 11 cm. diameter paper will provide a useful number of dye-papers which can be stapled together in the form of a booklet, with a plain paper cover. The dye-papers do not stain dry fingers and they can be made by unskilled labour in any laboratory.

For use in simple staining, a drop of distilled water is placed on the fixed film and a dye-paper placed on it; two more drops of water will give enough concentration of dye to stain the bacteria in the operative time. The paper is then washed off and the film dried.

Papers soaked in the following dye solutions are now in use for simple staining: aqueous crystal violet, aqueous and carbolic fuchsin, and aqueous safranin. Aqueous or carbolic methylene blue is used for demonstrating granular diphtheroid bacteria, and for counterstaining after carbol fuchsin in staining spores by the Ziehl–Neelsen method (carbol fuchsin is followed by a sodium sulphite paper). Carbol fuchsin papers are used for staining capsulated cells and flagella[1].

The advantages of the dye-paper method, with the dyes so far tested, include: (1) elimination of fluid stains in bottles; (2) economy of dye; (3) economy of storage space; (4) non-spoilage (as by rubber, oxidation, etc.); (5) ease of preparation; (6) negligible cost.

## Elimination of Inconclusive Results in the Treponemal Immobilization Test

WORKING with Nichols's pathogenic strain in th treponemal immobilization test, it is a commo experience[1] that some sera constantly yield inconclusive results and, further, that from time to time whole series of results must be discarded, becaus one or another of the controls shows poor surviva of the treponemes.

When the test is performed in an atmosphere o 95 per cent nitrogen and 5 per cent carbon dioxid 'contaminated' with about 0·2 per cent oxygen inconclusive results are relatively often obtained Even when all oxygen is removed by slow passag of the air through a heated tube of quartz filled wit copper chips, there still remain a few sera givin inconclusive results. Consequently, it is necessar to remove all the oxygen; but even then, satisfactor survival of the treponemes is not always obtained.

It was thought that great reducing power in th survival medium might be of importance. Henc the treponemal immobilization test was performe with a medium containing four times the concentration of sodium thioglycollate ('Difco') prescribed b Nelson.

Preliminary experiments with increased amount of sodium thioglycollate showed that it was possibl to get just as satisfactory results in the test with th above-mentioned oxygen-contaminated atmospher as with a 'normal' concentration of sodium thioglycollate in an oxygen-free mixture. When the tes was performed with four times the normal concentratio of sodium thioglycollate in an oxygen-free mixtur it was to be expected that none or only very fe sera would give inconclusive results. As a matte of fact, no inconclusive results have been observe since this modification has been employed (150 se examined).

Hence it is assumed that substances in the testicula extract from rabbits now and then are able to rais the oxidation reduction balance (redox potential of the medium to such a level that it is incompatibl with satisfactory survival of the spirochaetes. However, the same might happen in sera giving inconclusive results in experiments in which other se give satisfactory results. So far no bad influence the increased amount of sodium thioglycollate ha been observed.

Further experiments are in progress, and it intended to measure *Eh*, *rH* and *p*H through th different phases of the treponemal immobilizatio test. Special electrodes and beakers, manufacture by Radiometer, Copenhagen, have made this possibl

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

### Monday, June 8

British Society for the History of Science, Philosophy of Science Group (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. E. H. Hutten: "Models in Physics".

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Ian Stephens: "Two Principalities in Central Asia".

### Tuesday, June 9

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Madame S. Filitti Wurmser (Paris): "Étude quantitative de l'isohémagglutination humaine" *

### Wednesday, June 10

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Madame S. Filitti Wurmser: "Les isoagglutinines anti-B de divers génotypes".*

### Thursday, June 11

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Ronald Fisher, F.R.S.: "Population Genetics" (Croonian Lecture).

Mineralogical Society (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Sir Hubert Walker: "Some Problems in the Development of Air Transport in West Africa" (Ninth British Commonwealth and Empire Lecture).

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Vice-Principal (with honours degree in mechanical or aeronautical engineering, and considerable teaching and industrial or research experience)—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (June 13).

Assistant Lecturer in Physics (with good honours degree)—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (June 15).

Lecturer in Agricultural Zoology (preferably with special interest in ecology), a Lecturer in Physiology (preferably with special interest in the physiology of the special senses and neurophysiology), an Assistant in Zoology, and an Assistant in Physiology—The Secretary of University Court, The University, Glasgow (June 15).

Assistant Lecturer in Geology (with honours degree in geology, and preferably some research experience in stratigraphy and palæontology)—The Secretary, University College, Gower Street, London, W.C.1 (June 15).

Research Assistant (with degree in chemistry) in the Department of Chemistry and Biology, for polarography and other electrochemical techniques, general microchemistry and design of apparatus, etc.—The Secretary, Norwood Technical College, Knight's Hill, London, S.E.27 (June 15).

Entomologist at the Royal Army Medical College, Millbank—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4214/53 (June 18).

Lecturer in the Department of Physiology, Biochemistry and Pharmacology, to teach medical organic chemistry—The Registrar, King's College, Strand, London, W.C.2 (June 18).

Senior Scientific Officers as Research Engineers in the Royal Naval Scientific Service, for post (*a*) structural, (*b*) mechanical, (*c*) mechanical—hydraulics, in the Naval Construction Department, Bath—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S 4212/53 (June 18).

Assistant Experimental Officers (2) at the Forest Products Research Laboratory, Princes Risborough, for work on the strength of timber in its various uses—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.98/53A (June 19).

Demonstrator in Physiology—The Secretary, London Hospital Medical College, Turner Street, London, E.1 (June 20).

Geologist (with honours degree in geology, and preferably with experience in geological mapping and economic geology)—The Secretary, Southern Rhodesia Government, Rhodesia House, 429 Strand, London, W.C.2 (June 20)

Senior Principal Scientific Officer as Head of the Admiralty Petroleum Laboratory, Brentford—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4210/53 (June 25).

Senior Research Officer or Research Officer (with a degree in veterinary science and postgraduate training or experience in bacteriology or serology) at the Animal Health Laboratory, Parkville, Victoria, to carry out researches on approved aspects of bovine contagious pleuropneumonia, and to be responsible for the production of vaccine—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 201/74 (June 27).

Junior Lecturers (2) in Chemistry (one to teach Advanced Physical Chemistry and the other to teach Elementary Inorganic Chemistry and to assist in the supervision of First Year Laboratory Classes) at Auckland University College—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 15).

Senior Lecturer in Civil Engineering at the University of Queensland—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 31).

Applied Physicists and Research Engineers (senior and junior posts) in the Sheffield laboratories, for research in industrial metal working processes such as rolling and forging—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "Metal Working".

Assistant Biochemist (basic grade) (with university degree or equivalent) to work under general direction of group pathologist and senior biochemist—The Secretary, Preston Royal Infirmary, Preston.

Experimental Officers and Assistant Experimental Officers (Engineers or Physicists with a strong interest or research experience in electronics or telecommunications, line and radio) in the Royal Naval Scientific Service, in the London area and Gloucestershire—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.130/53A.

Lecturer (male) (with honours degree in agricultural science specializing in agricultural zoology, or honours degree in zoology) in the Biology Department, to give lectures in zoology as applied to agriculture, etc.—Dr. N. T. Gill, Harper Adams Agricultural College, Newport, Shropshire.

Physicist (with first- or second-class honours degree or equivalent in physics) in the Metallurgy Department, Royal Aircraft Establishment, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.136/53A.

Plant Pathologist (with honours degree in science and postgraduate research and practical experience in plant disease control) for investigational and experimental work in connexion with plant diseases, more particularly diseases of bananas, in the Cameroons Development Corporation Estates, West Africa—The Rubber and Mining Agencies, Ltd., 52 Leadenhall Street, London, E.C.3.

Vice-Chancellor—The Registrar, University of Otago, P.O. Box 56, Dunedin, New Zealand; or the Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1.

---

# REPORTS and other PUBLICATIONS

*(not included in the monthly Books Supplement)*

### Great Britain and Ireland

Sir John Cass College. Report, Session 1951–52. Pp. 20. (London: Sir John Cass College, 1953.) [204

Air Ministry: Meteorological Office. Meteorological Reports No. 12: Aviation Meteorology of the Route Marseilles—Rome—Athens—Cairo. (M.O. 535g.) Pp. ii+68. (London: H.M. Stationery Office, 1953.) 2*s.* 6*d.* net. [204

Department of Scientific and Industrial Research: Radio Research. Special Report No. 23: Characteristics of the Ionosphere Observed in Great Britain, 1930–1946. Pp. vi+16. (London: H.M. Stationery Office, 1953.) 1*s.* 6*d.* net. [204

British Museum (Natural History). Guide for the Identification and Reporting of Stranded Whales, Dolphins, Porpoises and Turtles on the British Coasts. By F. C. Fraser and H. W. Parker. Second edition. Pp. viii+42. 2*s.* Instructions for Collectors, No. 3: Reptiles, Amphibians and Fishes. Sixth edition. Pp. 28. 9*d.* (London: British Museum (Natural History), 1953.) [214

Report of the Proceedings of the 1952 Conference of the Universities of Great Britain and Northern Ireland, convened by the Committee of Vice-Chancellors and Principals, and held in the William Beveridge Hall, University of London, Senate House, on Friday and Saturday, December 12th and 13th, 1952. Pp. 103. (London: Association of Universities of the British Commonwealth, 1953.) [214

British Non-Ferrous Metals Research Association. Thirty-third Annual Report, 1953. Pp. 59. (London: British Non-Ferrous Metals Research Association, 1953.) [214

Fire Protection Association. Technical Booklet No. 11: A Comparison of the Extinguishing Effects of Chlorobromomethane Methyl Iodide and Carbon Tetrachloride. By E. H. Coleman. Pp. 12. Technical Booklet No. 12: The Surface Spread of Flame on Surfaces treated with Nitrocellulose Lacquers. By R. W. Pickard. Pp. 12. Technical Booklet No. 13: The Heating of Panels by Flue Pipes. By D. I. Lawson, L. L. Fox and C. T. Webster. Pp. 20. (London: Fire Protection Association, 1952.) [214

Annals of the Cape Observatory. Vol. 15: Stellar Parallaxes (3rd, 4th and 5th Series) determined in the Years 1931–1938 with the Victoria Telescope of the Royal Observatory, Cape of Good Hope, under the direction of Dr. J. Jackson. Pp. vii+315. (London: H.M. Stationery Office, 1953.) 35*s.* net. [214

Wool Industries Research Association. Report of the Director of Research for 1952–53. (Publication No. 196.) Pp. 27. (Leeds: Wool Industries Research Association, 1953.) [214

Metallurgical Abstracts, General and Non-Ferrous. Vol. 19, 1951–52. (New Series.) Editor: N. B. Vaughan. Pp. iv+511. (London: Institute of Metals, 1952.) [284

Commonwealth Relations Office. The Colombo Plan: Technical Co-operation Scheme. Report for 1952 by the Council for Technical Co-operation, Colombo, February 1953. Pp. 10. (London: H.M. Stationery Office, 1953.) 6*d.* net. [284

Society of Chemical Industry. Chemical Engineering Group. Proceedings, Vol. 33, 1951. Pp. viii+82. (London: Society of Chemical Industry, 1953.) 42s. [304

Cambridge University Educational Film Council. Sixth Report, 1953. Pp. 8. (Cambridge: Cambridge University Educational Film Council, 1953.) [304

Textile Institute. Annual Report, Balance Sheet and Accounts for 1952. Pp. 20. (Manchester: Textile Institute, 1953.) [304

University of Leeds. Report to the Worshipful Company of Clothworkers of the City of London of the Advisory Committee on the Departments of Textile Industries and Colour Chemistry and Dyeing during the Session 1950–51. Pp. 41. Report to the Worshipful Company of Clothworkers of the City of London of the Advisory Committee on the Departments of Textile Industries and Colour Chemistry and Dyeing for the Session 1951–52. Pp. 38. (Leeds: The University, 1951–1952.) [304

Science Museum. Navigation Today: a Special Exhibition at the Science Museum, London, from April–September 1953. By D. Chilton. Pp. v+21+7 plates. (London. H.M. Stationery Office, 1953.) 1s. 6d. net. [304

The Work of Aslib for the Year ended December 1952. Pp. 22. (London: Aslib, 1953.) [304

Philosophical Transactions of the Royal Society of London. Series A: Mathematical and Physical Sciences. No. 904, Vol. 245: A Transformation of the Hodograph Equation and the Determination of certain Fluid Motions. By T. M. Cherry. Pp. 583–626. (London: Cambridge University Press, 1953.) 9s. 6d. [304

Journal of Photographic Science: Section B of *The Photographic Journal*. (Bi-monthly.) Vol. 1, No. 1. January–February. Pp. 40+viii. (London: Royal Photographic Society, 1953.) Subscription, 25s. per annum. [304

Royal Institute of Chemistry. Lectures, Monographs and Reports, 1953, No. 2: Plant Growth Substances. By Dr. R. L. Wain. Pp. ii+16. (London: Royal Institute of Chemistry, 1953.) 5s. net. [304

Registrar General's Statistical Review of England and Wales for the Year 1951. (New Annual Series, No. 31.) Tables, Part 1, Medical. Pp. x+474. (London. H.M. Stationery Office, 1953.) 12s. 6d. net. [304

## Other Countries

Southern Rhodesia. Report of the Trustees and Director of the National Museums of Southern Rhodesia for the Year ended 31st December, 1952. Pp. 22. (Bulawayo. National Museum, 1953.) [94

Some Elementary Notes on the Theory of Phase Contrast Microscopy. Pp. 18. (Zeist: Nederlandsche Optiek- en Instrumentenfabriek Dr. C. E. Bleeker N.V., 1953.) Free. [94

Annals of the New York Academy of Sciences. Vol. 56, Art. 3: Virus and Rickettsial Classification and Nomenclature. By Sir MacFarlane Burnet and 28 other Authors. Pp. 381–622. (New York: New York Academy of Sciences, 1953.) 4 dollars. [204

Canada. Department of Mines and Technical Surveys, Mines Branch. Technical Paper No. 1: The Determination of Thorium in Ores by the Column Method. By R. J. Guest. Pp. vi+24. 25 cents. Technical Paper No. 2: The Constitution of Bone China, Part 1, High Temperature Phase Equilibrium Studies in the System Tricalcium Phosphate-Alumina-Silica. By P. D. S. St. Pierre. Pp. v+107. 50 cents. (Ottawa. Department of Mines and Technical Surveys, 1953.) [204

Proceedings of the California Academy of Sciences, Fourth Series. Vol. 27, No. 18: Some Hepaticae from the Galapagos, Cocos and other Pacific Coast Islands. By Lois Clark. Pp. 593–624 (plates 37–41). (San Francisco: California Academy of Sciences, 1953.) [204

Commonwealth Scientific and Industrial Research Organization. Bulletin No. 271: Timbers for Battery Separators. By L. N. Clarke. Pp. 28. (Melbourne: Commonwealth Scientific and Industrial Research Organization, 1953.) [204

New Zealand Marine Department. Fisheries Bulletin No. 10a: A New Zealand Trout Stream; some Facts and Figures. By K. Radway Allen. Pp. 70+8 plates. (Wellington: Government Printer, 1952.) [204

Bulletin of the Bingham Oceanographic Collection. Vol. 14, Article 1: The Striped Bass, *Roccus saxatilis*. By Edward C. Raney, Ernest F. Tresselt, Edgar H. Hollis, V. D. Vladykov and D. H. Wallace. Pp. 177. (New Haven, Conn.: Yale University, 1952.) 3 dollars. [204

California Institute of Technology. Annual Report, 1951–1952. Pp. v+110. (Pasadena: California Institute of Technology, 1953.) [204

United States Department of the Interior: Geological Survey. Geological Survey Circular 229. Water-loss Investigations, Vol. 1, Lake Hefner Studies; Technical Report. Pp. viii+153. (Washington, D.C.: Government Printing Office, 1952.) Free. [204

Royal Society of New Zealand. Report of the Seventh Science Congress, Christchurch, May 15–21, 1951. Pp. vi+256. (Christchurch: Royal Society of New Zealand; London: High Commissioner for New Zealand, and Wheldon and Wesley, Ltd., 1953.) [204

Pasteur Institute of Southern India. Annual Report of the Director together with the Forty-fifth Annual Report of the Central Committee of the Pasteur Institute Association, 1951–52, and Scientific Report 1952. Pp. 62. (Coonoor: Pasteur Institute of Southern India, 1953.) [204

Forest Research in India, 1948–49. Part 1: The Forest Research Institute. Pp. iv+111. (Delhi: Manager of Publications, 1952.) 8.6 rupees; 13s. 6d. [204

Southern Rhodesia. Climate Handbook Supplement No. 1: Climatological Tables for the Period July 1931 to June 1951. Pp. 158. (Salisbury: Government Printing and Stationery Department, 1952.) [204

United States Department of Agriculture. Agricultural Handbook No. 46: Mosquitoes of the Northwestern States. By H. H. Stage, C. M. Gjullin and W. W. Yates. Pp. 95. 35 cents. Circular No. 903: Stink Bugs on Seed Alfalfa in Southern Arizona. By H. B. Russell. Pp. 19. 10 cents. Farmers' Bulletin No. 1895: Land Slugs and Snails and their Control. Revised edition. Pp. 8. 5 cents. Farmers' Bulletin No. 2040: Control of Potato Insects. By J. H. Dudley, Jr., B. J. Landis and W. A. Shands. Pp. ii+52. 20 cents. Farmers' Bulletin No. 1323. The Wheat Strawworm and its Control. By W. J. Phillips and F. W. Poos. Revised edition. Pp. ii+6. 5 cents. Farmers' Bulletin No. 1798: Control of Common White Grubs in Cereal and Forage Crops. By Philip Luginbill, Sr., and T. R. Chamberlin. Revised edition. Pp. ii+14. 10 cents. Leaflet No. 237: Control of Mole Crickets. Revised edition. Pp. 8. 5 cents. Leaflet No. 184: The Elm Leaf Beetle. Revised edition. Pp. 4. 5 cents. Leaflet No. 325. Control of the Alfalfa Caterpillar. Pp. 5. 10 cents. Technical Bulletin No. 1045: Evaluation of Fumigants for Control of Insects attacking Wheat and Corn in Steel Bins. By H. H. Walkden and R. B. Schwitzgebel. Pp. 20. 10 cents. (Washington, D.C.: Government Printing Office, 1951–1953.) [214

Smithsonian Institution: United States National Museum. Annual Report for the Year ended June 30, 1951. Pp. iv+112+5 plates. Annual Report for the Year ended June 30, 1952. Pp. iv+103. (Washington, D.C.: Government Printing Office, 1952–1953.) [214

World Health Organization. Technical Report Series No. 60: Working Conference on Nursing Education; Report. Pp. 30. 0.80 Sw. francs, 1s. 6d.; 20 cents. Technical Report Series No. 62: Expert Committee on Hepatitis; First Report. Pp. 26. 0.80 Sw. francs; 1s. 6d.; 20 cents. Monograph Series No. 11 Epidemiology and Control of Endemic Syphilis; Report on a Mass-Treatment Campaign in Bosnia. By Dr. E. I. Grin. Pp. 93. 4 Sw. francs, 5s; 1 dollar. Monograph Series No. 13: Malaria Terminology; Report of a Drafting Committee appointed by the World Health Organization. By Sir Gordon Covell, Dr. Paul F. Russell and Dr. N. H. Swellengrebel. Pp. 82. 4 Sw. francs; 5s., 1 dollar. (Geneva: World Health Organization; London: H.M. Stationery Office, 1953.) [214

Australian National Antarctic Research Expedition. A.N.A.R.E. Reports, Series B, Vol. 2: Botany—The Mosses of Macquarie Island and Heard Island. By H. T. Clifford. Pp. 12+3 plates. (Melbourne: Department of External Affairs, Antarctic Division, 1953.) [214

Food and Agriculture Organization of the United Nations: Plant Production Branch, Agriculture Division. World List of Plant Breeders; Supplement to List of Plant Breeders in Canada and the United States of America published in September 1949. Pp. vi+105. (Rome: Food and Agriculture Organization of the United Nations; London. H.M. Stationery Office, 1952.) [304

European Timber Trends and Prospects: a Study prepared jointly by the Secretariats of the Food and Agriculture Organization of the United Nations and the United Nations Economic Commission for Europe. Pp. xvi+315. (Geneva: Food and Agriculture Organization of the United Nations; London: H.M. Stationery Office, 1953.) 14 Sw. francs; 25s.; 3.50 dollars. [304

European Timber Statistics, 1913–1950: Statistiques Européennes du Bois, 1913–1950. Pp. v+168. (Geneva. Food and Agriculture Organization of the United Nations; London: H.M. Stationery Office, 1953.) 7 Sw. francs; 12s. 6d.; 1.75 dollars. [304

Scientific Council for Africa South of the Sahara. Publication No. 3: Directory of Scientific and Technical Libraries in Africa South of the Sahara. Pp. 61. (Kikuyu: Scientific Council for Africa South of the Sahara, 1953.) 2s. 6d. [304

Survey of Egypt. Survey Department Paper No. 52: The Artesian Water of Egypt. By G. W. Murray. Pp. iv+20. (Giza: Survey of Egypt, 1952.) 400 mills. [304

Annual Reports for 1941–51 of the Pathological Division of the Rubber Research Institute of Malaya. Pp. 50+34+34. (Kuala Lumpur: Rubber Research Institute of Malaya, 1953.) [304

Notas de Fisica. No. 8: On the Spread of the Soft Component of Cosmic Radiation. By G. Molière. Pp. 5. No. 9. Non-Relativistic Equation for Charged Particles with Spin 3/2. By J. Tiomno. Pp. 9 (Rio de Janeiro. Centro Brasileiro de Pesquisas Fisicas, 1952.) [46

Annalen van de Sterrewacht te Leiden. Deel 20, Tiende en elfde Stuk: Improved Elements of 84 Southern Cepheids, by C. J. Van Houten; Discussion of 43 Variable Stars in a Region around CPD − 31° 5547, by P. Th. Oosterhoff and Miss J. A. Horlick. Pp. 273–318. (Leiden: Sterrewacht, 1952.) [4

Mémoires de la Société de Physique et d'Histoire Naturelle d Genève. Vol. 42, Fascicule 3. Distribution de la radioactivité e Suisse. Par Roger Payot et Adrien Jaquerod. Pp. 253–320. (Genève Georg et Cie., 1953.) 10 francs. [4

Rapid Chemical Micromethods for the Analytic Fractionation o Serum Proteins. By Dr. William Q. Wolfson and Dr. Clarence Cohn Pp. 15. (Ann Arbor, Mich.: The Overbeck Company, 1951.) [8

World Health Organization. Technical Report Series No. 64 Expert Committee on Influenza; First Report. Pp. 32. (Geneva World Health Organization; London: H.M. Stationery Office, 1953. 1s. 6d.; 20 cents; 0.80 Swiss franc. [8

Fondation Universitaire. Trente deuxième Rapport Annuel, 1951-1952. Pp. 135. (Bruxelles: Fondation Universitaire, 1953.) [8

South Australia. Report of the Museum Board, 1st July 1951 t 30th June 1952. Pp. 9. (Adelaide: Government Printer, 1953.) [8

United States Department of Commerce: Weather Bureau. Technical Paper No. 20: Tornado Occurrences in the United States Prepared by Climatological Services Division. Pp. iii+42. 35 cents Technical Paper No. 19: Mean Number of Thunderstorm Days i the United States. Prepared by Climatological Services Division. Pp. 22. 15 cents. (Washington, D.C.: Government Printing Office 1952.) [8

## Catalogues

A Thousand Notable Books, 1470–1952. (Catalogue No. 732. Pp. 92. (London: Francis Edwards, Ltd., 1953.)

Cambridge Electrical Instruments, Abridged Specifications (List No. 163A.) Pp. 36. (London: Cambridge Instrument Co., Ltd. 1953.)

Focus on Columax Magnets. Pp. 4. (Sheffield: Swift Levick an Sons, Ltd., 1953.)

Silanes and Organo-Silicon Products. (Technical Bulletin No. 2. Pp. 8. (Chadwell Heath: Hopkin and Williams, Ltd., 1953.)

Verlagsverzeichnis. Bucher and Zeitschriften seit 1946 stan August 1951. Pp. 60. 1 Nachtrag, Bucher und Zeitschriften stan April 1952. Pp. 16. 2 Nachtrag, Bucher und Zeitschriften stan February 1953. Pp. 16. (Stuttgart: Georg Thieme Verlag, 1953.)

# THE BASIS OF RESEARCH

IN the address on the significance of information in present-day industrial society which Prof. T. U. Matthew delivered to the Aslib Conference at the Hayes, Swanwick, last September, he rightly stressed the value of personal contact and initiative, although his theme was the extension and specialization of information services. This factor is often overlooked, and while Prof. Matthew suggested that the information function should now be formally recognized as a new function of management, and that the effective use of existing information depends largely on the extent to which management is 'information minded', he quite as explicitly recognized the vital importance of the initiative, enthusiasm and personality of the information officer or librarian himself. There was no suggestion that we can solve the problem of securing the effective utilization of existing knowledge by relying purely on mechanical means, such as adequately equipped libraries and information services, efficient organization or the latest and most elaborate devices for recording, filing and finding information.

To a large extent this view was reflected in the subsequent discussion; but one remark made by Prof. Matthew, and the discussion centring on it, suggest that the limitations of mechanization are still far from being fully understood; we are apparently not without danger of attempting to set up elaborate organization or equipment to do what will always be done more effectively by personal contact, and the cross-fertilization of minds which results therefrom. New information, said Prof. Matthew, is accumulating in scientific literature at a rate much faster than can be used effectively. That, of course, has always been true and is likely to remain so—no system of coding and indexing chemical compounds is likely to result in more than a mere fraction of the vast number of organic chemical compounds becoming more than laboratory chemicals. It is not surprising that the chlorinated diphenylethane now known as DDT should have remained a laboratory curiosity from its synthesis in 1874 until its value as an insecticide was recognized in 1939 as a result of a systematic search for moth-repellents. What is surprising is that Prof. Matthew and those who questioned him on the point should be so disturbed at a position which has many parallels. Scores of chemical substances have been prepared, described and recorded in the literature, and remained of a purely scientific interest until some technical development made urgent, for example, the discovery of products for use in accelerating the vulcanization of rubber, in preventing the oxidation and deterioration of rubber, fats and oils, foodstuffs, textiles and other materials, in preventing the icing of aeroplane wings or the freezing of the cooling systems of internal combustion engines, for the control of some pest or the treatment of some disease in animals or human beings. Once the need is recognized and the technologist can begin to formulate the requirements of the product he desires, it is often a simple matter to work by analogy through a series of compounds until one is found which will provide at any rate a temporary solution.

Often, it is true, that is the starting point for extensive applied research, and even for more fundamental work; but it is well to remember that necessity is still the mother of invention. The limits of information services must be recognized, as indeed Prof. Matthew emphasized. No information service can supply the answer until the appropriate and specific question is put to it: it is no part of the process of invention or creation, though information services are an indispensable tool of the inventor and an invaluable aid to the creative worker.

In stressing, therefore, the contribution which efficient and adequate library and information services can render to technical and economic development, care should be taken not to claim too much. It is equally important to view the relations between science and technology in a proper perspective. Technology and applied science are not necessarily synonymous terms: not all technology has grown out of science; some science has grown out of technology. Engineering, for example, is sometimes described as applied physics, and it is true that to a large extent physics provides the theoretical basis for engineering. Nevertheless, from the earliest times down to the present, the technology has often come first, and only afterwards has physics supplied the explanation or theoretical basis. Frequently physical advance has depended on engineering science supplying the instruments and equipment for its investigations, and sometimes also the fundamental knowledge has been acquired in the course of what might be described as technological studies or research.

Indispensable as may be the help of the librarian or information officer to the research worker, the technologist or the industrial manager and administrator, mere mechanical efficiency and comprehensiveness must not be our objective. As Prof. E. Bright Wilson, jun., remarks in a recent book, "An Introduction to Scientific Research", wise selection rather than all-inclusiveness is the key to library work. Intelligent individuality and enthusiasm are the right counter to the cramping or isolating tendency of the growing mass of recorded scientific and technical information, and this applies to the user of such information as well as to the librarian.

For that reason alone, no improvements in abstracting services, indexing practices or other mechanical means for the dissemination of information and co-operation in information services will ever eliminate the need for contact between individual scientists and technologists themselves. It is probable, indeed, that even informal contacts, particularly where research is concerned, do in practice far more than is commonly appreciated to bridge the gaps in existing coverage of scientific and technical periodicals by abstracting services, and that in consequence the omissions to which Dr. S. C. Bradford directed attention twenty years ago are in any event not sufficiently serious to justify the expenditure of effort and resources which would be required to give complete cover. However that may be, the British Commonwealth Scientific Conference in Australia last yea fully recognized the importance of personal contact between scientists through visits to countries of th Commonwealth. Such visits were rightly regarded a fundamental to the success of Commonwealth collaboration in science, and the Conference attache the greatest importance to generous governmen provision being made to facilitate such visits.

Although the Conference was concerned mainly with the exchange of visits within the Commonwealth, it was manifestly equally aware of the valu of the interchange of visits with scientists of othe countries also. Free movement of scientific men across national frontiers and the reduction of vis and passport formalities and other restrictions to th minimum consistent with national security are a firs condition of scientific and technical advance, thoug admittedly the situation to-day is one in which balance has to be struck in any one country betwee opposing considerations. That balance should, however, be struck with a full appreciation of the pric that has to be paid, and should take full account o changing economic and other conditions which may rapidly upset the appropriateness of the balanc struck at any particular time.

If due care is taken in this respect and decision are manifestly seen to be reasonable and not arbitrary or archaic by those directly affected, much less harm may be done to the interchange of thought and o information upon which the advance of science an technology depends. It is the former, indeed, that i vital, for progress depends above all on ideas. Th danger in restricting the flow of information lie mainly in the risk that the creative mind may b deprived at the critical moment of some piece o information that might supply the missing clue to new synthesis or invention.

There is, of course, the danger that the atmospher of secrecy or restriction always tends to depress o hinder creative activity. Such an atmosphere can b fatal to creative processes of any kind, and althoug Mr. Brewster Ghiselin compiled his anthology "Th Creative Process"* mainly with the view of assistin creative workers themselves to gain some insight int the factors or conditions which determine th efficiency or fruitfulness of their minds in creating and thus enable them consciously to increase th efficiency of developed and active intelligence, it ha a clear message for all those who are concerned with the control or direction of creative workers and th conditions under which they work.

Mr. Ghiselin does not distinguish clearly betwee creation and invention; but the anthology of writing collected in this symposium by some two score me and women who have paused to consider and describ the characteristics of their own creative processe cannot fail to help the creative worker who know little of this literature or where to find it. The scienti or technologist will note some surprising omissions—Helmholtz and Rutherford, for example, and Nicolle' "Biologie de l'Invention" and Graham Wallas's "Ar of Thought" are not quoted—and may find most interest in Poincaré's essay on mathematical creation, from "The Foundations of Science"; Einstein's letter to Jacques Hadamard, taken from "The Psychology of Invention in the Mathematical Field"; Herbert Spencer's conversation with George Eliot, taken from his autobiography; and R. W. Gerard's paper on the biological basis of imagination. The selection, from the point of view of the scientific worker, seems a little unbalanced, though allusions in Mr. Ghiselin's introduction and in Mr. Gerard's paper restore the balance slightly; but there is much more than Mr. Ghiselin's introduction to the volume to give unity to the book. There are passages in some of the accounts of how composers and poets work, such as in Morton Prince's remarks on subconscious intelligence underlying dreams, which recall and repair some of the more obvious omissions—a well-known passage in Nicolle's "Biologie de l'Invention", for example—and the scientist or technologist who reads these varied accounts will find much that bears closely on his own inventive efforts.

---

* The Creative Process: a Symposium. Edited by Brewst Ghiselin. Pp. xii+259. (Berkeley and Los Angeles: University California Press; London: Cambridge University Press, 1952 6.50 dollars.

It is not suggested that the evidence here presented of the way, in varied fields, in which creative minds work is likely to help the reader, whether scientist or not, to manage his own creative processes, assuming he is capable of such work. In fact, there is clear evidence that at a certain stage too much conscious control of thought may kill the new idea which the unconscious mind is developing. Mr. Morton Prince's account of the writing of a poem as a subconscious process, following a dream and vision which had succeeded several days of attempts to write verse and of reading much poetry, recalls both Sir J. J. Thomson's remark that new ideas about a subject come when one is not thinking about it, though one must have thought about it a good deal before, and the way in which sudden insight or the solution of a problem sometimes seems to occur at the moment of waking.

This point has frequently been stressed in disussions of the subject, notably by C. Nicolle in "Biologie de l'Invention", by W. B. Cannon in "The Way of an Investigator" and especially by J. Livington Lowes in his study of the working of Coleridge's imagination. This last, "The Road to Xanadu", is the only one mentioned by Mr. Ghiselin, and although he emphasizes the parallel between Lowes's study nd the biological study of Dr. Gerard, so far as the scientific man is concerned this book can be usefully supplemented by others such as those of Poincaré nd Hadamard, or by following up the clues suggested in some of the chapters of Prof. W. I. B. Beveridge's "The Art of Scientific Investigation".

What emerges most clearly from this anthology is hat while we can do little positively to encourage he creative process, the moment of intuition or illumination, or the act of invention, it is fatally easy o discourage or repress such moments of vision or creation. Every care should be taken to avoid the disturbances that are fatal to such activity, though it not suggested that it is practicable or desirable for he creative worker, be he inventor or scientist or artist, to be immured in an 'ivory tower'. Indeed, to do so would often remove the vital stimulus and the intellectual stress and tension that precede creation.

Few have brought out the position better than Helmholtz, who distinguished three stages in the act of invention or creation: first, a period of preparation in which the problem is examined; next, a period of incubation, in which often the mind is not consciously occupied with the problem; and third, the moment of illumination, which is usually spontaneous and unpredictable. To these, Wallas and Poincaré add a fourth stage, that of verification when the subject is worked out in its entirety. A very similar analysis was given by Sir Henry Cohen in his Harveian Lecture, "Harvey and the Scientific Method", in March 1950, and clearly the first and last stages call for conscious hard work, and for a determined effort animated by a passion for the subject. At the first stage also, stimulus—not, however, distraction of the type already suggested—can be fruitful.

It is in the full sense of all that is involved in preparation of this type that Pasteur's adage applies, "Chance only visits the prepared mind"; or, in the words of Nicolle, "Chance favours only those who know how to court her". This granted, it is of the second and third stages that we need to take care and in the sense indicated by Helmholtz's well-known remark: "Happy ideas come unexpectedly without effort, like an inspiration. So far as I was concerned, they have never come to me when my mind was fatigued, or when I was at my working table. . . . They came particularly readily during the slow ascent of wooded hills on a sunny day".

Sir Michael Sadler put it similarly: "The ideas come—not when I am under great strain or threadbare with overwork, but after a period of rest (including physical exercise and distraction of thought) following on a period of very hard work and of grappling with real unsought difficulties . . . the ideas come to me unsought and I find them in my mind exactly as I might find a half-crown that somebody had put into my pocket while my coat was hanging up in my absence". To the testimony of Helmholtz and Sadler the attention of the administrator might well be directed. He can do little to assist the mobilization of the contents of memory, which C. J. Renier defined as the essence of imagination, still less to assist the perception of the value of qualities which in Shelley's view was the essence of imagination. Administrative action can scarcely protect the artist or the investigator from the anxieties and strains to which their fellow men are exposed, and indeed from such tensions may result the stimulus to some great moment of discovery, creation or invention. There are, however, innumerable smaller matters that can seriously prejudice such moments by the irritation and distraction they cause, and with these the administration is closely concerned. Restrictions on the interchange of scientific or technical information may, for example, well deprive the man of science of some invaluable fact or clue which in the period of incubation his subconscious mind may transmute into some new idea or insight. Even if harm is not done in this way, he may be deprived of the invaluable stimulus of personal contact, or the irritation engendered by unnecessary restrictions may cause a frame of mind utterly opposed to that tranquillity in which Helmholtz found new ideas came most readily.

That is the real reason why restrictions on scientific intercourse and the exchange of information should be such as manifestly commend themselves to scientific men as reasonable, and are accordingly accepted without a feeling of irritation or frustration. We do not yet know how the imagination works, but we know at least some of the conditions which are inimical to it. Mr. Gerard's paper does not indeed take us a great way further than Lawes, with whose brilliant analysis of the working of Coleridge's mind, in effect, he starts. Creative imagination, to Mr. Gerard, is an action of mind that produces a new idea or insight, and while he admits that a satisfactory interpretation of imaginative phenomena in terms of neural mechanisms is a matter for the future, his discussion of the psychology, anatomy, pathology and physiology of imagination in essence largely confirms the conclusions reached by others who have attempted to record their experience of the creative process. He points clearly to the danger of reason stifling imagination; and the challenge to education which the teaching of rigour without stifling imagination still presents is set forth unmistakably.

Nor are the emotional factors overlooked. Quoting Pavlov's insistence on the need for passion, in the conscious work preceding that of imagination, Gerard remarks that the unconscious work goes on over problems that are important to the waking mind only when the mind's possessor worries and cares passionately about them. This, it is true, relates to the conscious work recognized by Poincaré and Helmholtz as preceding the unconscious work of imagination—to the mastering of accumulated knowledge, gathering new facts, observing and experimenting, developing technique and skill, selection and discrimination, which are all more or less conscious and voluntary activities, as Ghiselin points out.

To the second period of conscious work recognized by Poincaré as preceding the unconscious work of imagination Gerard attributes, however, a second emotional factor—that of courage. Without courage the unfamiliar will not be faced, or that which is different or new espoused, no matter how well prepared the climate of opinion may be. It is at least arguable that certain anti-scientific trends to-day have enhanced the importance of this emotional factor. At the best, invention is liable to be precluded by distrust of deviation. Ghiselin's anthology will not give much fresh guidance as to the working of the creative mind, or how the process of invention or creation occurs. None the less, it shows clearly enough that the mind in creation and in preparation for creation usually requires some management; and to the creative worker and to the administrator alike it indicates both conditions which are favourable to the creative process and also some of the factors, disturbingly active to-day, which discourage creative and imaginative work in science, art and technology, and which cause the waste and frustration to which Mr. Ghiselin directs attention.

# ALBERT HEIM (1849–1937)

Albert Helm

Leben und Forschung. By Marie Brockmann-Jerosch and Arnold and Helene Heim. Pp. 268+15 pl. (Basel: Wepf and Co., 1952.) 17.80 Swiss francs.

SCOTS geologists a few years ago were commemorating the one hundred and fiftieth anniversary of the death of James Hutton (1726–97). Now Swiss geologists have issued a volume to mark the centenary of the birth of Albert Heim (1849–1937). Towards the close of the fifty-odd years separating the two events, Arnold Escher von der Linth reported on wonders of large-scale tectonics, which he had recognized in the Glarus Canton and neighbouring regions of the Alps. It was in relation to these wonders that Heim achieved unique international fame. Two of his publications are outstanding, his "Mechanismus der Gebirgsbildung" (1878) and his "Geologie der Schweiz" (1919–22). Heim was fortunate at both ends of his career, fo inheritance from Arnold Escher allowed of a flying start, while support received from pupils, especiall his son Arnold Heim, was of great service in late years. In addition, he was a very remarkabl man.

The book here under review considers this remarkable man from a number of different aspects: fo example, his family life, tectonic and glacial research drawings and relief models, academic activities application of geology to welfare and safety, joy i mountains, breeding of Newfoundland dogs, an finally ethics, including total abstinence.

The child Heim promised well; but it seems tha he would have been lost to science except for a strang accident. He came to be afflicted with recurren headaches, so much so that he had to be remove from school and set to work on a farm. Here, fortunately, in 1865, he was overrun by a shy-hors (*von einem scheu gewordenen Pferd*) with its cart i tow. It broke him in seven places; but whe eventually he got out of bed, though he had t supplement a shortened leg with a thick sole to h boot, his head was clear and he was able to resum his studies.

Many anecdotes enliven this book. They ar written with becoming piety, but not without humou There is, for example, the story of a trick Baltze played during the 1907 celebration of the centenar of the London Geological Society. Heim, on retur from Oxford, where he had received an honorar doctorate, found an invitation from a lord (*ein Lords*) to a reception in evening dress. Heim, wit a strong prejudice against dress clothes, declin with thanks. Then arrived a package with a lett purporting to come from the lord, "who regarde it as an honour to offer the great scholar Hei evening clothes for his reception". Baltzer an his conspirators were repaid with no little anxiet during the ensuing ceremony lest Heim shoul elude them and publicly thank the lord for h ***Aufmerksamkeit***.

In 1920 the trickster was Dame Nature herself. fissure opened on the mountain face above the villa of Linthal, threatening a landslip of 100,000 cub metres. The cleft was kept under observation ar increased daily by 1–27 mm. Eventually Hei delivered a speech to the villagers, the draft of whi occupied some fifty pages. He besought them evacuate; but their hesitating partial concurren drove him to despair and brought him sleeple nights. Then, though blocks continued to thunder into the valley, the mass as a whole came to a standstill. It is sad to read that their escape led the inhabitants to ridicule geologists in general, and Heim in particular. As a rule, however, Heim's advice on practical matters won great respect; and among the people at large he was better known for his views on water, tunnels, avalanches and landslips than for his theories on mountains and glaciers.

Heim was not only a first-class field geologist and an excellent writer, but also an artist, who found expression in drawings and relief models. Probably geologists have learned more from his pictures and sections than from those of any other, except perhaps W. H. Holmes, of Grand Canyon fame, and W. M. Davis, of altogether different style. It is interesting, too, that it was passion for relief modelling that introduced Heim to geology.

When not quite ten years old, after his first mountain trip with his father, Heim began to reproduce what he had seen by pasting together little stones and capping them with sugar in place of snow. When twelve he saw for the first time a genuine relief, and realized what he had been striving to attain. Then he found a 1 : 50,000 map of the Glarus Canton exposed in a shop window; and a year of window-gazing and perpetual intercession persuaded his parents to spend the 3 francs necessary for its purchase. Modelling from this map in potters' clay brought only short-lived joy, for Heim soon realized that the map was incorrect. So in 1865 he got permission to wander for eight days among the Tödi mountains and make drawings of his own for guidance. Thus during the next year he was able to include a relief of the Tödi group, 1 : 25,000, among his drawings for the Canton school examination. Hearing of it, Escher, though a stranger, called at his father's house to see this exploit of a schoolboy; and, recognizing its worth with delight, invited its young author to attend his excursions. In these Heim came to realize that to produce a really correct model of a mountain one must learn its composition and development.

Heim with his own hand did much of the backward engraving on stone or copper required for reproduction of his illustrations, often setting up the original in front of him and proceeding without further help. He published his first panorama at about the same ime as he exhibited his Tödi model. In after years when he took his students to the mountains, he would halt them and say: "Let us draw".

As might be expected, the book gives us the tale of Heim's conspicuous mistake, the Glarus double fold, and of his splendid recovery in 1902. Perhaps, however, the most welcome single feature is a full eport of a speech Heim made on his eightieth birthday, when he led his last excursion to the Locheitenkalk at the type locality of the Glarus overhrust. In it he explained that for the past few years he had been searching through half-published and unpublished records of Escher's observations, and had come to realize as never before the fullness of his master's appreciation of nappes in the make-up of the Helvetian Alps.

It is a small matter, but British geologists will be pleased to see reproduced Heim's portraits of Peach and Horne, the "Investigator Twins" as he happily alled them. These portraits he sketched during a famous excursion to the North-West Highlands in 1912.

E. B. BAILEY

# A HARMONY OF PROPORTIONS

## Symmetry

By Hermann Weyl. Pp. vii+168. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1952.) 24s. net.

THIS intriguing book represents what was, in effect, Prof. H. Weyl's farewell to the Institute for Advanced Studies in Princeton. It deserves to be read by anybody who not only desires some guidance through the subtleties of symmetry, but who also is willing to respond to the æsthetic bearing of the subject. This link is the essence of the author's contribution: it is fundamentally more important than the elegant proofs of transformations, translations and rotations which occur in abundance. For, after all, with a little trouble they can be found elsewhere, but the examples of symmetric ornament cannot. Perhaps it is admissible to remark that here we have a new—and most welcome—recruit to the very restricted literature of shape in relation to beauty (both natural and artificial) associated particularly with the names of Birkhoff, Speiser and (as editor) Whyte. On the periphery comes Wittkower and his treatise on humanist architecture. Thus, these pages cannot be read in isolation; whatever their exact origin may have been, their outlook is too synthetic and their implications for the whole of culture too wide. Symptomatic of the age, they are distinguished by their emphasis upon a topological habit of mind, and by a certain sturdy objectivity in showing that many of the delights of Nature are but straightforward examples of a minimal-energy economy, rather than instances culled from metaphysical speculations. In this way, Prof. Weyl does good service to science without introducing ontological arguments set in a plane of discourse for which they are often inappropriate. At the same time, there is an undercurrent of sympathetic understanding for the artist, whose works are necessarily unique, and incapable of inclusion in any algebra of classes.

The reader is confronted with four main divisions —bilateral symmetry; translatory, rotational and related symmetries; ornamental symmetry; and crystals. Appendixes deal with the highly specialized subjects of 'proper' and 'improper' rotations.

In his choice of historic examples of mathematical embellishment, the author excels. This is where the book is *sui generis*, good as the formal parts undoubtedly are. The Sumerians had a passion for strict bilateral devices; by contrast, Western tendencies were to loosen rigid symmetry. To the crystallographer there is something compelling in a design such as that of the Etruscan tomb of the Triclinium. Here we meet with a certain 'imperfection' (akin to 'real' crystals) which, judged by formal standards, makes the pose of the horsemen and the stance of the animals on the side-panels much more interesting than they would otherwise be.

Turning to architecture, Prof. Weyl mentions the great central church of S. Maria degli Angeli at Florence (by Brunelleschi) which is octagonal. As he remarks, pentagons and hexagons are rarer, though, as a matter of fact, they occur in designs in Serlio's fifth book of 1547. Apparently, deliberate structures seldom simulate the five-fold character, so frequent in the floral kingdom.

All this, and more, is to be found in this well-produced little volume. Occasionally we hear of encouraging signs that men of science and humanists are not only trying to find common ground for studying natural and man-made forms by comparative methods, but are also succeeding. Here, indeed, is a book to help them. F. I. G. Rawlins

# ZOOLOGICAL LITERATURE OF 1950

## The Zoological Record

Vol. 87, being the Records of Zoological Literature relating chiefly to the Year 1950. Edited by G. Burder Stratton. Pp. vi+1507. (London: Zoological Society of London, 1953.)

The serious student of zoology is greatly indebted to the Zoological Society of London for the production of the annual volumes of the "Zoological Record" in spite of continually increasing costs. It is difficult to imagine how any systematist could ever succeed in tracing the literature of his subject without this annual list of titles of zoological papers, published usually within thirty months or less of the end of the year to which any particular volume relates. The present volume, No. 87, deals principally with the literature of 1950 and comprises more than thirteen thousand references, classified into eighteen sections, and a final chapter giving a list of new generic and sub-generic names.

The activity in different branches of the subject is to some extent indicated by the number of titles in each section, ranging from Porifera, with only sixty-six titles, up to Insecta, which overwhelms all other sections with a total of 3,101 titles, almost a quarter of the whole volume. A glance through these sections reveals some rather unexpected figures, for under Aves one finds more than sixty new species and subspecies recorded, although the ordinary zoologist would have imagined that at least in this class very few new forms remain to be discovered.

Each section begins with a list of titles followed by a subject index briefly indicating the papers dealing with particular branches. Thus the subject index of Protozoa has sections on text-books, history, biography and obituary, bibliography, taxonomy, technique, structure, physiology, locomotion, sexuality, effects of environment and stimuli, effects of chemicals, development, evolution and genetics, ecology (including parasitism), economics and distribution (both geographical and geological) and, finally, a systematic index. The sections may be purchased separately from the Zoological Society of London (Regent's Park, London, N.W.8), except for the section "Insecta", which is obtainable only from the Commonwealth Institute of Entomology (41 Queen's Gate, London, S.W.7). It is rather surprising that, judging from the sales, more use is not being made of these sections of the "Zoological Record", for as a result of various donations they are supplied at a price far below the cost of production.

Zoologists are greatly indebted to the specialists responsible for the compilation of the various sections, and whose services are obtained more or less on a voluntary basis. One notable change occurs on the title page. The present volume is edited by Mr. G. Burder Stratton, librarian of the Zoological Society of London, whose name replaces Dr. A. Malcolm Smith, who has been editor of the "Record" since 1938 and to whom zoologists throughout the world owe a special debt of gratitude for his valuable services. Edward Hindle

# INDIA'S FOOD PROBLEMS

## Food and Population and Development of Food Industries in India

Pp. xv+357. (Mysore: Central Food Technological Research Institute, 1952.) 10s.

Of all the free nations of the world, few have more difficult food problems than the Union of India. The population is about 357 millions, an increase of some 40 millions over that of 1941; the area of sown land per head in 1951 was 0·6 acre and has long been shrinking, for in 1911 it was 0·9 acre. This shrinking area has to provide not only food but also cash crops, especially cotton and non-edible oil seeds. Some land is still unused, but it usually has some disability more or less difficult or costly to remove; there is still the possibility of more irrigation which would enable the land to carry two crops a year instead of one and also to give higher and more certain yields. But meanwhile the health services are improving: anti-malarial operations are saving great numbers of lives, and it has been estimated that, even if all the optimistic plans of 1951 could be carried through, the nation's food position in 1956 would be no better than it is to-day.

One of the most hopeful features in this difficult situation is the seriousness with which Indian agriculturists and food experts are dealing with it. The numerous problems involved were discussed in two impressive symposia held in May 1951 at the Central Food Technological Research Institute in Mysore, a remarkable organization under the direction of Dr. V. Subrahmanyan: both food production and food processing were dealt with. The papers are collected in this volume, and they give an admirable summary of the ideas and methods of the Indian experts and of the problems as they then stood.

The discussions ranged chiefly around the possibilities of increasing production of food grains, of increasing yields of all crops, improving methods of storage and preservation, reducing wastes and losses, and utilizing more widely foods at present confined to certain localities but capable of considerably higher output per acre than those at present grown. The main facts are already well documented; but they are set out here with great clarity and in handy form. If there is a certain amount of repetition, it is justified by the grim importance of the subject.

Serious complications arise in India from the circumstance that the choice of food is governed not simply by economic but also by social and religious factors: custom especially plays a large part. Great numbers of the population will eat only rice as their staple food, although cassava would give much higher yields per acre. Dr. Subrahmanyan has ingeniously made a 'synthetic rice' by moulding a mixture of tapioca and groundnuts into grains of the size and shape of rice grains; how far these will prove acceptable remains to be seen. Other possibilities discussed include the utilization as human food of various oilseed residues, groundnut and others, at present fed to cattle or used as manure. The current grain shortage is about 10 per cent of the total consumption, but this is increasing yearly: Indian agricultural experts are making great efforts to narrow or even close the gap. The book gives an excellent description by the workers themselves of the way they are setting about their task. E. John Russell

## The Yearbook of the Universities of the Commonwealth, 1953

(Thirtieth Issue.) (Published for the Association of Universities of the British Commonwealth.) Pp. liv+1805. (London: G. Bell and Sons, Ltd., 1953.) 63s. net.

THE Commonwealth Universities' "Yearbook" has become firmly established as a 'hardy annual' and one the blooms of which grow bigger with each successive year. The edition for 1953 (the thirtieth) is larger than ever because the staffs and activities of the individual universities are increasing and because new institutions are continually being established. Thus the present edition contains new entries for three Indian universities (Baroda, Bihar and Visva-Bharati) and for one in Pakistan (Karachi); in Canada the Nova Scotia Technical College now has a full entry on becoming a member of the National Conference of Canadian Universities, and in the United Kingdom the entry for Southampton has been moved from the college to the university section.

In Appendix 1 of the "Yearbook" the usual account of the qualifications required for admission to a first-degree course in United Kingdom universities has been augmented with similar material for Canada, Australia and South Africa. The eight other appendixes have all been revised and in some cases increased, especially Nos. 2 and 3, dealing with United Kingdom postgraduate awards tenable at home and overseas, respectively. The introductory surveys that are to be found at the beginning of each national section have also been considerably revised and, in particular, those for Canada, India and Pakistan completely rewritten. The name index now runs to 151 pages, with a grand total of thirty thousand names.

The seventh quinquennial congress of the universities of the Commonwealth will be held in Cambridge later this year, and this volume should prove of inestimable value to the delegates as a reference work; but its usefulness will not be confined to the congress, for experience shows that this volume is a reference book which quickly shows honourable marks of constant use.

## Introduction to Metamathematics

By Prof. Stephen Cole Kleene. (Bibliotheca Mathematica, Vol. 1.) Pp. x+550. (Amsterdam: North-Holland Publishing Co.; Groningen: P. Noordhoff N.V., 1952.) 32.50 fl.

THERE will be a warm welcome for a book of this nature by one who is a distinguished member of the American mathematical fraternity. Outside the *Journal of Symbolic Logic*, which cannot be expected to be suitable for teaching purposes, it is hard to find an English text wholly fitted for university work in meta-mathematics. The advantage of the present volume is that it contains practically everything necessary (somewhat massive as it is) between the same two covers.

There are four main sections, namely, the problem of foundations, mathematical logic, recursive functions, and some additional topics in mathematical logic. Actually, the last is almost a supplement dealing with the predicate calculus and consistency proofs. It may not always be wholly advisable to follow the author's preference for starred and unstarred paragraphs: the same applies in general to an encounter with Gödel's two famous theorems before tackling the lemma establishing the primitive recursive character of certain predicates. But these are details. The main strength of the development followed by Prof. Kleene stands out at the end of Part 1, where he collates the essential ingredients of the 'full picture'. These are (*a*) the informal theory, (*b*) the object theory, and (*c*) the meta-theory, in which (*b*) is examined.

An adequate bibliography, a list of symbols and notations, and an index bring a most valuable compilation to a close.

F. I. G. RAWLINS

## Chemistry in Action

By Prof. George M. Rawlins and Alden H. Struble. Second edition. Pp. viii+575. (Boston, Mass.: D. C. Heath and Co.; London: George G. Harrap and Co., Ltd., 1952.) 21s.

THIS book describes a one-year course in chemistry for American high-schools. The author's plan seems to be to make chemistry attractive by stressing fascinating applications of it to everyday affairs. The scope covers approximately the requirements of the British matriculation syllabus, with the addition of more than a hundred pages on hydrocarbon chemistry; this permits alluring discussions on such topics as textiles, food, penicillin, stain-removal and insecticides. The whole is built on a rather slight framework of theory. The book is replete with illustrations; most of the half-tone plates illustrate not fundamental principles but interesting and occasionally sensational applications of the science. Much information is given in the form of tables, and some by picture and caption only. There are many sets of questions and numerous reading references.

The worth of the book is its content of interesting up-to-date factual matter. Pleasing to look at and read, it would serve to acquaint a non-scientist with the role of chemistry in everyday life. There is too little of the grammar of science for the book to be used in Britain as an examination text, but, as a supplementary reader or as an aid to a teacher to brighten his lessons, it is worth consideration.

G. F.

## General Genetics

By Adrian M. Srb and Ray D. Owen. (A Series of Biology Texts.) Pp. x+561. (San Francisco: W. H. Freeman and Co.; London: Bailey Bros. and Swinfen, Ltd., 1952.) 5.50 dollars; 47s.

AS a text-book for courses in elementary general genetics, this book constitutes a welcome addition. There are features which make it valuable, though unfortunately the price is not one of these. First, there is novelty and variety in the choice of examples; second, the illustrations are particularly effective; third, the developments of the past ten years are amply dealt with; and fourth, there is a very salutary discussion of the principles involved at every step in the logical sequence of the chapters. This last quality ensures that the student will be well aware of the fields in which genetical theory is most promising and of those in which it is weaker. Among the criticisms which might be made, one is shared with all other previous text-books, namely, the inconsistent use of the words "gene", "allele" and "locus", though, of course, a good deal of the inconsistency is in the nature itself of the concepts. Another criticism is that the chapters on quantitative inheritance and on population genetics are rather slight. On the whole, this text-book is likely to be useful to those who have the task of teaching elementary genetics to students who have a varied background and not much of it at that.

G. PONTECORVO

# THE LIFE AND TIMES OF SIR RICHARD GREGORY, BT., F.R.S., 1864–1952*

By SIR HAROLD HARTLEY, K.C.V.O., F.R.S.

IT was at our meeting last year at Belfast that for the first time for more than fifty years we missed the presence of our most constant member, whose friendships and devotion to science, and his keen mind and sense of humour had given him a unique position as a vitalizing and constructive force in the work of the British Association. It is most fitting that this Pedler Lecture, which was his way of commemorating the work of Sir Alexander Pedler as secretary of the British Science Guild, should be a tribute to the life and work of our old friend Richard Gregory himself.

His life-history is a record of successful endeavour that would have delighted the heart of Samuel Smiles as an example of what courage and grit and devotion to science can accomplish. It is a thrilling story of heredity, circumstance, education and opportunity. Gregory was proud of his ancestry, and in his study hung a photograph of the inscription to his grandfather, a shoemaker of Bideford:

"He was a consistent member of the
Wesleyan Society for 65 years,
And as a local preacher and Class Leader,
His Labours were blessed
To the Salvation of Many Souls."

John Gregory, his son, followed the same craft but also was one of Nature's poets. I found among Richard's papers this charming letter from H. G. Wells to the old man when Richard had sent him one of his father's slender books of verse in 1907.

> "Dear Mr. Gregory,
>
> "You will I hope forgive my writing to you to tell you how much I like and value your book of poems. Your son has just given it to me and I have been reading in its contents a constantly increasing delight and surprise. He had often told me you wrote verse but he had given me no idea of the simple, curiously straightforward graciousness of your songs. They come I think most appropriately with this spring time; they have so much in common with the bright freshness of primrose and aubrietia and all the daffodils and narcissuses with which the garden is singing. I have been reminded of Blake and Herrick and of all that is most truly English as I read. R.A.G. is one of my earliest friends—I didn't expect at this date to find a quite new reason for liking and respecting him—in such a book as this.
>
> "I am myself a sort of literary man though I've never risen to either verse or science. That must be my excuse for bothering you with these praises.
>
> "Yours very sincerely,
> "H. G. WELLS."

Richard was born in 1864 in Bristol, where his father had moved from Bideford. When he was six he went to the Wesleyan Day School at Baptist Mills, where three hundred boys were taught in groups in one large schoolroom heated by a single fire-grate. In 1874 he entered the secondary school, now called Queen Elizabeth's Hospital, a boarding school with a uniform rather like Christ's Hospital, where his interest in science began. He left school early owin to his delicate health and began life like Faraday a a newspaper boy, and with his father more intereste in poetry than shoe-making, it sometimes happene that his mother could buy no food until Richar returned with his weekly earnings. John Gregor must have had something in common with Blak and his idealism left its mark on Richard. One o his poems reveals his attitude towards wealth:

"My heaven is not paved with gold;
For all that has been writ of it,
I would not have it if I could,
There's blood on every bit of it.

I would not harm my angel's feet
With such a hateful use of it;
I loathe, I scorn the thought unsweet,
Because of man's abuse of it."

When Richard was fifteen he was apprenticed t a boot factory for five years to learn the trade o clicking, that is, cutting out the various shapes o leather that were to be the uppers of boots and shoes. He was unhappy in his work and spent all his spar time attending evening classes in the Bristol Trad and Mining School (now the Merchant Venturers College) and reading in the St. Agnes Club Library

John Gregory was one of a band of socialis reformers in Bristol actively engaged in establishin the socialist and labour movement. The grou included Ben Tillett, Jim O'Grady, later Sir Jame and High Commissioner in the Commonwealth o Australia. Ramsay MacDonald joined them for short time in 1884 when he came to Bristol to hel with a boys' club. At that time he meant to becom a science teacher, and when he was Prime Ministe he said to Richard, "You chose the better part".

Richard and his father were great friends and i those early years he was closely associated with hi in his social work. At evening meetings John woul give an address on some labour problem or recit some of his poems and Richard would sing or give talk on a scientific subject, often astronomy, i which he was even then keenly interested. Joh Gregory became a well-known figure in Bristol an in 1912 he was given an honorary degree by th University, an honour which Richard was to shar with him thirteen years later.

When he was seventeen he won the Latin prize a the Trade School. Canon Wilson, a great education reformer, was then headmaster of Clifton; he wa an admirer of the personality and poems of Richard father and often came to see him. He encourage Richard with his Latin, and knowing his wish t leave the factory and learn science, he offered hi the vacant post of laboratory assistant at the Colleg Richard had to secure his release from his indentu and paid an indemnity of £5, which A. M. Worthin ton, the physics master, lent him, to be deducte from his first term's wages. One of his congeni duties at the College was the care of the fine eight-inc telescope.

---

* Alexander Pedler Lecture of the British Association, delivered in the Royal Institution, London, W.1, on May 28.

Here at last came the opportunity he had dreamt of during his years at the boot factory and he took full advantage of it, continuing his studies in science and mathematics to such good effect that three years later he gained a scholarship in the Science and Art Department examinations which enabled him to become a science teacher in training at the Royal College of Science, South Kensington. Huxley was then dean of the College, and a new world opened for Gregory. He gained first classes in astronomy and physics and two years later, in 1887, he became a science demonstrator in H.M. Dockyard at Portsmouth. His main interest was still astronomy, and in 1889 he returned to the Royal College of Science as computor to the Solar Physics Committee and assistant to Norman Lockyer.

At each stage of his life Gregory was fortunate in his friends. At South Kensington he and H. G. Wells were fellow students and they were close companions. Wells has described in "Love and Mr. Lewisham" and in his "Experiments in Autobiography" the aims and hopes and struggles of the students of the College at that time. Forty years later he wrote of Gregory: "He emerges in my memory as a bland and sturdy figure in the debating society, a little troubled then as ever about the letter 'r', friendly, hilarious, hard-up and working hard, one of the cheerful and often quite audible group which includes William Burton, the potter, and A. T. Simmons. We had no relatives to push us on, we had to do all our own pushing, and sometimes the pushing was very hard indeed.

"Gregory pushed his upward course by way of sunspot computation to the stars. He won the respect and confidence of Sir Norman Lockyer. But before his footing was well established there were some precarious times. I had not so much pushed my way up as out by starting the *Science School Journal* (which is now the *Phoenix*) and similar depravities and my times were even more precarious. We collaborated in a book on 'Physiography' (Gregory got the job for me) and earnt £10 each. Ten pounds were worth getting in those days. We lent each other money and returned it (though social observers declare that such returns never happen). We followed our destinies. All sorts of things happened to me but nothing ever changed the steadfast friendship and helpfulness of Gregory."

Gregory's work with Lockyer was of a routine nature, measuring the areas and positions of sunspots and faculæ in photographs taken during 1878–81 at Dehra Dun, Mauritius and Melbourne. He was also concerned in some unproductive work on the widened lines in sunspot spectra and he photographed the spectra of a number of elements. That was his only direct contact with research, and his name does not figure in any paper. But Lockyer's work on the orientation of temples in Greece and Egypt appealed to Gregory and was the start of his life-long interest in the relations of astronomy and religion.

Soon after he joined Lockyer's staff, Gregory's articles and reviews began to appear in *Nature*: in 1889 "On the Determination of Masses in Astronomy" and "The Planet Uranus"; in 1890 on "Comets of Short Period", "Lunar Photography" and "Electrical Storms on Pike's Peak". In the same year he became an Oxford University extension lecturer on astronomy and physics, and in 1892 he left the Royal College to become a free-lance lecturer and writer. Lockyer, however, had realized the quality and promise of his literary work and in 1893 made him assistant editor of *Nature*, which first brought him into touch with Macmillans, its publishers. So the opportunity came to Gregory to devote his life to securing recognition for science and scientists, and to ensuring that they were given the chance to make the contribution to progress on which he believed the future depended. He had come up the hard way and he did his best to awaken a realization of the readjustments in social and economic conditions that the new technical age was making imperative. Gregory used every means of reaching his objective: education, journalism, the British Association and the British Science Guild.

## Education

Gregory had had to fight so hard for his own education and had suffered so much from the lack of text-books that he saw here a great opportunity. His first book, "Elementary Physics and Astronomical Geography", was published in 1891. It was the first of many text-books that flowed from his ready pen or were inspired by his editorship. His own books were notable for their clear writing, systematic arrangement, for their recognition of the relation of theory and practical work, and for the lively interest they created in the practical applications of science. His second book was an elementary physiography, a description of the laws and wonders of Nature. After that came "Honours Physiography" with H. G. Wells in 1893, and in the same year "The Vault of Heaven", and next year "The Planet Earth". Meanwhile, he was getting experience as an Oxford University extension lecturer and in 1898 he became professor of astronomy at Queen's College. The same year saw the beginning of his long partnership with A. T. Simmons, with whom he started the *School World* (later incorporated in the *Journal of Education*) and the series of joint text-books, which they produced in new editions until Simmons's death in 1921.

In 1905 Gregory became scientific editor to Macmillans, a position he held until 1939. Under his editorship and inspiration some two hundred text-books were published, many with him as co-author.

In the years when science was becoming an increasingly important subject in the schools, this comprehensive series of text-books covering elementary and advanced courses was a contribution of great value. Gregory devoted himself to this work, and many authors, young and old, were grateful for his encouragement and his wise advice and criticism. Editorship for him meant a working partnership with the author at every stage of a book.

But his interest in education did not end with writing and editing books. He was keenly interested in the technique of teaching, in the many problems to be found in the introduction of what was often a new subject and in securing the proper place for science in the curriculum. It was these wide interests that led him to take such an active part in the formation of Section L (Education) of the British Association in 1901. He was its first secretary and then its recorder, and one of its most active members from the start. The turn of the century had seen a big extension of school science and many experiments were being tried.

Gregory, in his presidential address to Section L, when it came of age in 1922, gave a sketch of its aims and progress. It had been formed to devote attention to education in all its branches with the object of introducing scientific conceptions into every sphere of educational activity. Gregory defined the business of education as the promotion of the right adjustment of a growing human being to its environment. The scope and character of the subjects of instruction should be determined by this biological principle and must be adjusted to new conditions in the world. "Science has become a kingdom potent with possibilities for good or evil—an inheritance which cannot be renounced—and to let any children grow up unfamiliar with their entailed possession is to neglect an obvious duty. . . . Science permeates the atmosphere in which we live, and those who cannot breathe it are not in biological adjustment with their environment—are not adapted to survive in the modern struggle for existence."

Gregory knew the kind of science teaching he wanted to see in schools; its purpose was not "to prepare for vocations but to equip pupils for life as it is and as it soon may be".

He was chairman of a British Association Committee in 1917 which was appointed to report on the essential place of science in school education. It included among its members several outstanding teachers like Sanderson of Oundle and Archer Vassall, and the report with its suggestions for science courses was the foundation of the movement towards general science. Gregory insisted that general science should be more than an amorphous collection of topics from physics and chemistry with a little natural history thrown in as a sop to the biologists. "It should provide for good reading as well as for educational observation and experiment; should be humanistic as well as scientific. The subject which above all others has the double aspect is geography. . . . Rightly conceived, geography can be made the earliest means of education as both Comenius and Locke regarded it, and it can be used as the unifying principle of all the generalized scientific instruction in schools." To-day with our greater knowledge of the world's resources and demands, of the needs of backward countries, of the principles of nutrition and disease, Gregory's forecast is seen in a new light.

He was very critical of examination syllabuses of the type of university entrance examinations which meant sacrificing the needs of the many to the interests of the few. While recognizing the value of laboratory work as a training in method, he was insistent on its being accompanied by broad courses which would excite wonder and stimulate the imagination, while providing a knowledge of everyday phenomena and the applications of science. His address was a plea "for the expansion of scientific instruction in this humanizing spirit, and for widening the gateway into the land of promise where the destinies of the human race are shaped. . . . I want science not only to be a means of stimulating real and careful thinking through doing things, but also a means of creating interest and enlarging the working vocabulary of the pupils and thus truly increasing their range of intelligence. So may scientific instruction be made a power and an inspiration by giving, in the words of the Book of Wisdom (vii, 16–20):

"An unerring knowledge of the things that are,
To know the constitution of the world and the operation of the elements;
The beginning and end and middle of time,
The alternations of the solstices and the changes of seasons;
The circuits of years and the position of stars;
The nature of living creatures and the raging of wild beasts,
The violences of winds and the thoughts of men,
The diversities of plants and the virtues of roots."

The late Poet Laureate shared Gregory's views. He spoke at the great meeting that was held in May 1916 to direct attention to "The Neglect of Science" which was prejudicing in many ways our war effort. It is probably scarcely even a memory to many; but the recollection of it is a reminder of the progress we have made since then, thanks in no small degree to Gregory's persistent advocacy. Robert Bridges in his final sentence crystallized the inward significance of this new view of scientific learning in the schools. "It is," he said, "the living grammar of the universe, without which no man can ever hope to read in its full significance the epic of his spiritual experience."

For his presidential address to the Science Masters' Association in 1928, Gregory chose as his subject "Contacts of Science and Literature". "As my main functions in life," he said, "seem to be those of a scribe and guide, it is perhaps appropriate that in this address I should deal with language and literature in relation to science rather than with scientific education or progress." Gregory was an omnivorous reader all his life and he had a good literary memory. He begins by comparing the outlook of the scientist and the poet, the one desiring to see things as they are, the other to display the emotional feelings aroused by them. But as Gregory shows by quotations from Tennyson and Shelley, their intentions are not necessarily opposed. Scientific truth may often be turned to poetic purpose. He quotes the verse from "The Cloud":

"I am the daughter of earth and water,
And the nursling of the sky;
I pass through the pores of the oceans and shores;
I change, but I cannot die."

Those lines had often been set for comment in elementary science examinations, and Gregory wonders whether students of English could interpret them so successfully. That leads him on to question whether the indifference to science among the teachers of English is not more general than the neglect of literature by students of science. Gregory was always pressing for a balanced education, and he resented the intransigent attitude of scholars and writers educated in classical schools towards the claims of science to an essential place among the new humanities. He rejects on the evidence of the psychologists the concept that the exercise of the mind on one kind of material improves the faculty to deal with all kinds of material, part of the basis of the claim that training in the classics is of unique value. But Gregory was a Hellenist with a deep appreciation of "the passionate regard for truth, disinterested research, imagination, acute reason and creative intelligence, which were the essence of the Greek spirit". He admits that "to certain minds a grammatical generalization is more readily understood than a principle derived from laboratory measurements, and on that account some pupils who have been trained to apply scientific method to language may be better prepared to take up the study of science seriously than those in whose minds are nothing but loose ends". What judgment could be fairer? And he ends with an appeal to teachers of English, classics and history to understand and interpret the human contacts of science with their own subjects, resulting in "a unity of interest which will give power and a new meaning to all cultural effort".

His book "Discovery" was one of Gregory's many services to education. Published in 1906, it ran through many editions until in 1949 Gregory revised and shortened it for the Penguin Press, so that the younger generation will not read it in its original form. This I regret, as it had a quality of its own in giving a picture of the working of the minds of the great discoverers. Instead of following the historical sequence, Gregory's chapters deal with the different aspects of discovery: outlook and endeavour, the scientific mind, belief and evidence, law and principle, scientific motive and practical purpose. The book is a revelation of his wide reading, of his first-hand knowledge of the classics of science and of his amazing literary memory. It is interspersed with long quotations from the classic authors which are so aptly chosen that they fall imperceptibly into line with his own lucid lively sentences, while revealing the thoughts of many of the greatest scientists of the past and the literary quality in which they found expression. The quotations at the head of each chapter show, too, Gregory's range and discernment. The book has such freshness and vitality, it arouses human interest on every page, it is written with such zest and enthusiasm that it should be reprinted in its original form.

Sir Edward Salisbury, a few weeks ago, when he was opening the new biological laboratory of the University College of the South West of England, spoke of the present-day danger of specialization of the young scientist confined within the ever-growing complexity of his own field. Gregory's appeal was for some knowledge of the purpose and accomplishment of science by the young layman. His book "Discovery" seems to me so admirably suited to meet this dual need as an introduction which will arouse interest and stimulate wider reading. Gregory carried in his mind the whole story of discovery through the ages, he knew the personalities of the great men and their writings, and so with the touch of the journalist at his best, carrying his learning lightly, he has given us this vivid picture of the different aspects of the advance of knowledge. Astronomy, geology, biology, chemistry and physics are all woven together, as he drew his examples from the old masters and the new.

### Journalism

Almost from the day that Gregory became Lockyer's assistant in 1889 he was writing popular articles on astronomy, and Lockyer was quick to see the qualities—his lucid style, his gift of phrase, his sense of the significant—that were to make Gregory the greatest scientific journalist and editor of his time. Love of science and an imaginative sense of the part it was destined to play in human affairs were the mainsprings of Gregory's life. But in addition he had the shrewdness and the practical judgment, sharpened by his early struggles and adversity, which helped so much in the success of his editorship of *Nature*. Of all his presidential addresses—and he must easily hold the record both for their number and the variety of their subjects—his address on "Science and the Press" to the Association of Special Libraries and Information Bureaux (now Aslib) at Oxford in 1934 is in some ways the most significant as it contains a searching analysis of the parts an editor and a manager must play in the life of a newspaper. It reveals how his keen mind had appreciated the factors that make for success or failure. It is nteresting to compare it with the terse crisp sentences n which C. P. Scott wrote "On Journalism" in the centenary number of the *Manchester Guardian*. The two men thought alike. "In all living things," wrote Scott, "there must be a certain unity, a principle of vitality and growth. It is so with a newspaper, and the more complete and clear this unity, the more vigorous and fruitful the growth. . . . A newspaper has two sides to it. It is a business, like any other, and has to pay in order to live. But it is much more than a business; it is an institution; it reflects and influences the life of a whole community; it may affect even wider destinies. It is, in its way, an instrument of government. It plays on the minds and consciences of men." *Nature* under Gregory certainly became an institution, both in the international and in the national fields, for he made it a clearing-house for new ideas. A letter to *Nature* became the accepted channel of rapid communication to the scientific world of a preliminary note of some new technique or discovery. But that was only one of its functions.

Lockyer made Gregory his assistant editor twenty-four years after he had founded *Nature*. As years went by, more and more of the work fell to Gregory and he was virtually editor a long time before Lockyer resigned the office to him in 1919. Gregory had his own ideas, and new features were introduced, like the leading articles, the first of which appeared in October 1915 on "Science in National Affairs". From November 1919 when he took over, they appeared every week, many from his own pen, dealing with scientific developments which had national importance. Some of their titles in 1919–20 indicate Gregory's wise discrimination and foresight in the subjects he chose: the nurture of key industries, the need for aircraft research, the organization of scientific work in India, meteorology and the State, science and the new Army, the cost of scientific publications, the present state of the dye industry, naval education, aerial navigation and meteorology.

The years of Gregory's editorship saw an immense increase in the number of scientific workers and a rapid growth of specialization with the increasing complexity of problems in each field. Entirely new fields of investigation were opened with new techniques, and there was a great extension of industrial research. All this combined to make it more difficult to watch developments all over the world. But under Gregory's skilful guidance *Nature* made this possible.

The late Lord Rayleigh, in thanking him for his Hinchley Lecture to the Institution of Chemical Engineers, on "Scientific Knowledge and Action", spoke of the great debt that all scientific men owed to Gregory for more than a generation. Looking back on his own scientific life, he said that he found it difficult to imagine how he could have carried on if he had not had the constant privilege of reading the pages of *Nature*, a journal which kept one in touch with science in all its branches. I remember very well as a schoolboy being introduced to *Nature* by H. B. Baker—"dry reaction Baker"—and I read it eagerly each week. When I returned from a scholarship examination at Oxford, Baker greeted me by saying, "Well, your reading of *Nature* must have paid a good dividend", and from my point of view it certainly had.

Lord Rayleigh spoke of the nice discrimination with which *Nature* avoided any reference to discoveries like the death ray which were trumpeted in the daily press, and his own reliance on the authority of *Nature*. He wondered how Gregory managed to keep in touch with all branches of science in all countries; "but somehow or other the thing was done and scientists as a whole were glad to benefit by the result, even if they were mystified by the process".

In his early years Gregory stood almost alone as a scientific journalist, and in his Aslib address he lamented the scant encouragement given to science writers, since so few newspapers or periodicals had on their staff someone capable of dealing intelligently with scientific subjects, of equal standing with their special critics of art and music, or of racing, golf and tennis. As a result the public lack in science the enlightened guidance they receive in other matters. "Most people have yet to learn," he said, "how and why science and scientific thought are the determining factors in the chief problems of progressive life."

Gregory admitted that one difficulty was that many investigators were too busy and were often ill-fitted to be popular interpreters, which made it all the more important that there should be a class of science writers with some organization behind them, like Science Service, the non-profit-making corporation in the United States, founded in 1921 by a newspaper editor and proprietor, the late Mr. E. W. Scripps. He ended with an appeal to the press and to the men of science to get together and find a remedy.

That address was given nearly twenty years ago, and Gregory's advice has not gone unheeded. Particularly in the B.B.C. much has been done to make the public realize the outlook of the scientist and the impact of his work in almost every field of social and political well-being. Gregory took an active interest in establishing the Association of British Science Writers, of which he was the founder president.

It needed the experience of a Second World War to drive home the lessons of the First, but that demonstration of the power of science left in the minds of many a deep mistrust. Gregory himself repudiated the use of the atom bomb as repugnant to the ethics of the civilized world.

## British Association and British Science Guild

Of the many attachments Gregory formed during his life the longest and the most intimate was his membership of the British Association, and it was there that he was best known to the younger generation. He joined as a life member in 1896 and his attendance came near to being proverbial. In his telegram last year to us at Belfast he spoke of unbroken attendance at fifty-two meetings. From the first he threw himself into the work of the Association with immense energy and devotion, not only in Section L, but also on endless committees and as a member of Council for many years. He was always ready with constructive suggestions and he was one of the stalwarts who gave continuity to our meetings. The B.A. owed much to Gregory, but the debt was amply repaid when at the meeting in South Africa in 1929 he met in Johannesburg his future wife. She, too, has won our affection by her devoted care of her husband, who relied more and more upon her as years went by. Let me quote Gregory's own tribute to her: "My dear wife Dorothy has brought into my life more happiness than anyone else and whatsoever I may possess when I am called away cannot be more than a poor return for her sweet love and tender care".

But much as Gregory believed in the British Association, he followed Lockyer in thinking that its activities should be extended to influence public opinion and promote closer contact between science and public affairs.

In his presidential address at Southport in 1903 on "The Influence of Brain-Power on History", in which he paraphrased the title of Captain Mahan's famous book which did so much to arouse public interest in the Royal Navy, Lockyer urged the need for an organization to enable science to speak with a collective voice, so that it might counter the neglect which had become so dangerous, when Britain's industrial and military strength were both threatened with severe competition from abroad, competition based on education and scientific research. Lockyer gave striking figures to show how science was being starved in Britain as compared with the large sums being spent in Germany and the United States on the endowment of universities and research. He quoted Huxley's dictum that we were in the presence of a new "struggle for existence", a struggle in which science and brains take the place of swords and sinews, the result of which would be decided in the school, the university, the laboratory and the workshop.

It is perhaps difficult for the present generation to realize how backward we were. The total annual Government grant to universities and university colleges in Great Britain in 1905 was £155,000, while the University of Berlin ten years earlier was receiving £167,000. Lockyer pleaded for a duplicate of the Navy Bill of 1888 when £21½ million were voted for a five-year building programme.

Quoting the last words of the original objects of the British Association—"to obtain a more general attention to the objects of science and a removal of any disadvantages of a public kind which might impede its progress"—Lockyer argued that here was a great opportunity to expand its functions. "This magnificent, strong and complicated organization would become a living force, working throughout the year instead of practically lying idle, useless and rusting for fifty-one weeks out of the fifty-two so far as its close association with its members is concerned."

However, the Council did not see its way to set up such a wide organization as Lockyer had outlined possibly doubting the wisdom of becoming involved in national and political affairs. So the British Science Guild was formed in 1905, with Lord Haldane as its first president, with the objects of creating a general awareness of our future dependence on scientific method and research, of pressing for greater support for universities and research institutions, and of bringing to the notice of Parliament the scientific aspects of matters affecting the national welfare.

Gregory was at first a little doubtful about this breakaway from the Association; but he soon saw the advantages of the Guild as an agency for propaganda, backed by men in public life like Lord Haldane, Lord Sydenham, Lord Montagu of Beaulieu and Lord Melchett. By public meetings, by reports of committees, by lectures and by close contact with members of Parliament, it was able to stimulate public interest continuously during the critical years of scientific development. Some twenty urgen national problems concerned with scientific effor were investigated by strong committees, and in this way the Guild made a major contribution towards a number of improvements, among them: the Treasur grant for developing a National Physical Laboratory the creation of the Development Commission fo Agriculture; the establishment of a Department o Scientific and Industrial Research; the Patent Ac of 1932; and the formation of the Parliamentar Science Committee.

In all of this Gregory soon became the moving spirit, and from 1922 he was chairman of the Executive Committee. He drafted many of the reports, and the work of the Guild had strong support in *Nature*. He organized the exhibitions of British Scientific Products in 1918 and 1919, for which he received the recognition of a knighthood.

There is no doubt that the Guild did most valuable work, and the Norman Lockyer and Alexander Pedler Lectures founded in 1925 and 1929 were a constant reminder of the importance of science in human progress. In 1923, when the first suggestion was made to unite the Guild and the Association, Gregory was opposed to it, as in his view the two bodies were essentially different. "The B.A. consists of priests and noviciates of science, while the B.S.G. represents a missionary effort to proclaim a new gospel." Negotiations were renewed from time to time, and finally in 1936 proposals for amalgamation were approved by the British Association at the Blackpool meeting. In 1938 the Division for Social and International Relations of Science was formed with a committee embodying the existing British Science Guild Committee, with powers to hold meetings not necessarily confined to the annual meetings of the Association, and a new journal, *The Advancement of Science*, was substituted for the old annual report.

It is true that the Division under Gregory's presidency kept the Association active during the War. But looking back at what the Guild accomplished and looking forward to the problems Great Britain has to face, I question whether the fusion was in the best interests of science. Has not Gregory's original objection been fully justified by the results? The Guild could enlist the sympathy and leadership in the cause of science of men in public life. It provided a forum where a group of men of affairs could discuss with men of science. Under Lockyer's and later Gregory's watchful eye it could and did address itself immediately to national problems when science was concerned. Its success in later years was due largely to the energy and vision of Gregory and his friends. It was not only a missionary but also an invaluable watchdog. Has its offspring, the Parliamentary and Scientific Committee, effectively taken ts place?

## The Visit to America

In December 1938, just as he was leaving the editorial chair of *Nature*, Gregory was invited to give a series of lectures in the United States at the Carnegie Institution, Columbia, Harvard and Johns Hopkins Universities, and to address our sister body, the American Association for the Advancement of Science.

The tour was a great success, for Gregory was at his peak in his seventy-fifth year as an eloquent xponent of the gospel of science, and he felt the hrill of the occasion. He had seen clouds gathering n the horizon and his addresses were a declaration of his faith in what science could contribute to a disordered world if it were not perverted to destructive uses in the lust for power. Gregory feared the growing tide of nationalism as a disintegrating force in a world which science could help to unify. In 1938 he recalled oddy's Cassandra-like prophecy of the atom bomb.

The Greeks had dreams of the Golden Ages of the past, they had no word for progress; but Gregory had visions of the Golden Ages of the future, if man would use his new understanding of Nature to good purpose.

His Elihu Root Lecture to the Carnegie Institution of Washington, on "Cultural Contacts of Science", was the most finished and carefully argued of all his addresses, and it gave the best picture of the run of his mind and interests. It deserves to be reprinted, as it is unknown in his own country. In it he counters the view that scientists are materialists, insensitive to beauty and incapable of deep emotion, that the scientist's idea of the evolution of mankind is the law of the jungle, "Nature, red in tooth and claw". Through all his American addresses there runs the motive of his favourite quotation from Huxley, his dean at South Kensington, in "Evolution and Ethics": "In place of ruthless self-assertion it demands self-restraint in place of thrusting aside, or treading down or competition, it requires that the individual shall not merely respect but shall help his fellows; its influence is directed not so much to the survival of the fittest, as to the fitting of as many as possible to survive".

The future of the world depends, Gregory said, on the use of science in the spirit of the Sermon on the Mount.

One of the themes of the Elihu Root Lecture was the relation of science and literature. He quotes fine passages from Kepler and Newton, examples of de Quincy's "literature of power" as contrasted with "literature of knowledge", which "survive because of their human feeling naturally expressed". He quotes the famous passage in Wordsworth's introduction to Lyrical Ballads: "Poetry is the wealth and fine spirit of all knowledge . . . it is the impassioned expression which is in the countenance of all science". "Poetry," says Gregory, "and other forms of literary and artistic expression once followed more closely on knowledge than they do to-day. . . . Poetry, philosophy and science all began life together as children of one family. . . . The greatest singers of antiquity were the most alive to science." Then he turns to the history of the earliest science, astronomy—"The science most closely associated with spiritual feeling", and traces its relationships through the ages to religion and other reflexions of current thought in literature and philosophy. He follows the gradual emergence of the conception of law and order to Nature and of divine purpose through the study of celestial bodies in Babylon, in Egypt and in Greece. Then from his knowledge and love of literature he illustrates the inspiration that came from man's contemplation of the skies in the Bible and in the poems of Virgil and Lucretius, of Dante, Chaucer and Milton.

Through all this Gregory is tracing the pursuit of truth and its high moral and spiritual influence in whatever field it is the motive of action. Science is not to be regarded, "merely as a store house of facts to be used for material purposes, but as one of the great human endeavours to be ranked with arts and religion as the guide and expression of man's fearless quest for truth".

When he returned from America, Gregory collected all the materials for his lectures and embodied them in a book, "Religion in Science and Civilization". This was published in 1940, but alas nearly all the copies were destroyed in an air-raid, and then with his energy unabated at the age of eighty, he set to work and recast it under the title of "Gods and Men", which was published in 1949. Among the many appreciative letters he received about the book, those from Dr. George Trevelyan and Mr. Mackenzie King gave him special pleasure. Dr. Trevelyan said he was astonished that one who had given his life to science should have been able to take so wide and deep an interest in history. "I see you are a great age now which makes my wonder of the book all the more." Mr. Mackenzie King, writing just after his resignation of the premiership of Canada, said that the book had given him what he most needed—"A place of new beginning; something to restore a true perspective".

## Presidency of the British Association

In 1939 came the Second World War and Gregory had been elected president at Dundee the day before war broke out. The annual meetings of the Association had to be abandoned, but the formation of the Division for the Social and International Relations of Science gave the opportunity under Gregory's leadership for a series of conferences to discuss questions that would be in urgent need of solution when the War ended. The ideas of the founders of the British Science Guild were thus given scope for expression and action. There were eight conferences in all over which Gregory presided, and at the first, on "Science and World Order", he enunciated a "Declaration of Scientific Principles" which was in effect a Hippocratic Oath for scientists.

These conferences kept the Association in action during the War and they certainly achieved their object in providing opportunities for the discussion of post-war problems. Their subjects covered a wide field and perhaps the most successful were those on mineral resources, the place of science in industry, and science and the citizen, at which Gregory read a paper on "Science and the Press", in which he emphasized the need for continued education on the impact of science on social relations.

Gregory's was the record presidency of seven years, from 1939 until 1946, when he delivered his presidential address at the first short post-war meeting in July. His subject was "Civilization and the Pursuit of Knowledge". In it he recurs to the favourite topic of his later years, the gradual emergence of civilization through the ages and the history of early religion with its close association with the heavens. Then he outlines the development of the schools of philosophy and the growth of natural knowledge, science and invention. Gregory's anxiety was the use that man might make of his new powers, and he ends with a moving appeal for goodwill and goodness of heart in the choice between the good and evil fruits of knowledge.

His last speech to the Association was at Birmingham, when he moved the vote of thanks to Bishop Barnes for his Sunday evening discourse on "Science, Religion and Moral Judgments". The Bishop's subject was close to Gregory's heart and he was at his happiest in his appreciation of the address, with all his old zest and enthusiasm and his readiness to find *le mot juste*. We saw him for a brief space at Edinburgh, where he was taken ill; for a year he was an invalid and then in September 1952 his active spirit quietly flickered out.

## Epilogue

I began with the idea of making this lecture mainly a study of the times of Richard Gregory, but I quickly found those times becoming just a background to the human interest of his life of endeavour and success—a success which is so encouraging a story in the days when there were few of the educational escalators of the present time. I have told the story so far as possible in his own words, which were so well chosen.

Gregory's long life of nearly ninety years saw the most rapid and eventful changes in the outlook and fortunes of mankind. First came the battle between the evolutionists and creationists and the emergence of the liberal interpretation of the Holy Scriptures that we know to-day. Next came the gradual recognition of our social responsibility for the human adjustments that are needed in an industrial civilization, which has changed so profoundly the social structure of Britain. Alongside them came that pride of discoveries, the electron, the nucleus, the quantum and relativity, that have given a fresh insight into the nature of matter, of life and of the universe. With that deeper insight has come a new humility in response to the ever-receding vistas of the complexity of the unknown.

With the advance of knowledge came a new power of man over his environment, the possibility of a new partnership with Nature in place of the struggles of primitive man. Evolution has moved fast, quickened by the needs of two world wars, that have left such deep scars behind them.

Of all this Gregory, so far as science was concerned, was the interpreter, or as he called himself once 'the standard bearer', and he had ideal qualities for the task. He was no specialist, nor in that sense a profound thinker; he did not engage in the details of polemics. He saw the broad picture and its human bearings, for he was essentially a humanist. He had the gift of leadership—persuasive, resourceful and quick in action. He had a ready humour and a fund of stories. But above all he was one of the most generous of men, generous in his help and gifts, generous in his praise, and sometimes too generous of other people's motives.

Success and recognition came to him in many ways and he enjoyed them to the full. It was his generosity towards others that made his successes such a pleasure for his friends. The honours that pleased him most were his knighthood and his baronetcy, his election to the Royal Society under Statute 12 in recognition of his conspicuous service to the cause of science, his election to the Athenæum under Rule II, his honorary membership of the Old Cliftonian Society, the presentation to Lady Gregory and himself from the British Science Guild, and finally his presidency of the British Association.

Gregory was an optimist: he saw the best in everything and everybody. This made him sympathetic to new movements, which seldom came to him in vain for help. Perhaps, too, it was partly the inveterate old journalist in him peeping out, eager for news. From first to last he was a member of more than seventy societies and institutions and a moving spirit in so many. But it is as the editor of *Nature* that he will be best remembered in the future, for his wise, shrewd, imaginative guidance that gave *Nature* its unique position in the scientific literature of the world. The driving force behind all he did was his devotion to the interests of science and his belief in its message for the future. Gregory wrote his own epitaph:

> "My grandfather preached the Gospel of Christ;
> My father preached the Gospel of Socialism;
> And I preach the Gospel of Science,
> But the ethical principles of all three are
> pursuit of truth and righteousness for the
> improvement of man and society."

# STORAGE OF NORMAL TISSUE GRAFTS

A SYMPOSIUM, under the chairmanship of Dr. A. S. Parkes, on the "Preservation of Normal Tissues for Transplantation" was held in the rooms of the Ciba Foundation during March 16–18, 1953. Like other colloquia organized by the Foundation, its purpose was to provide not merely for the formal presentation of scientific papers but also for the informal discussion of problems of common interest to the participants. The symposium kept closely to the subject defined by the title; tumour transplantation was left aside because tumours are 'abnormal', and the storage of semen because semen is not a tissue.

Tissue storage, for practical medical purposes, is a storage of spare parts for surgical replacement. It is possible to envisage situations in which a patient's tissues might be stored for his own future use—for example, a surgeon might deliberately remove a little more skin than was necessary at an orthodox grafting operation, and keep the excess in store in case some of the grafts he actually used failed to heal properly—but for nearly all practical purposes, storage for replacement surgery entails the use of tissues from other human beings. This being so, the surgical use of stored tissues is bedevilled by the fact that some living tissues will not form permanent grafts after transplantation from one individual to another. They elicit immunity reactions which end by destroying them. Problems of tissue storage are thus closely interwoven with problems of tissue transplantation immunity.

In opening the scientific proceedings, Prof. P. B. Medawar (University College London) said that living skin, when transplanted into positions formerly occupied by skin, was probably the most exacting of all tissues in this regard; skin so grafted between one adult and another did not survive longer than a few weeks. Other tissues enjoyed special dispensations from the rigours of transplantation immunity, the nature of which could only be understood if the normal process of immunity were first defined. There is no doubt at all that intolerance of homografts had the properties of an actively acquired immunity reaction, but a reaction of what particular kind? A certain combination of properties points unmistakably to membership of that class of immunity reactions of which tuberculin sensitivity and sensitization to simple chemical compounds were also members. The most recently discovered of these properties, so Mitchison had found, was that immunity could be passively transferred by living cells but not by serum.

A homograft could be made more acceptable to its host either by changing the antigenic propensities of the graft or by modifying the reaction of its host. Under the latter heading, Prof. Medawar outlined experiments done in collaboration with R. E. Billingham and L. Brent which showed that if an animal were presented with living foreign cells in fœtal life, its power to react against those cells in later life was reduced or wholly abolished. This was not due, as had been widely assumed, to an adaptation of the grafted cells, but to an adaptation of the host, for 'actively acquired tolerance', once established by inoculation of the fœtus, extended to cells freshly transplanted in later life—cells which therefore had had no opportunity to adapt themselves to alien soil.

Dr. W. P. Longmire (University of California and U.S.A.A.F.) proceeded to survey the clinical uses of tissue homografts in general. One could make a broad distinction between homografts which had to be alive if they were to serve a permanently useful purpose, and homografts which could act as a guide and sometimes a stimulus to natural regeneration irrespective of whether they remained alive or not. Skin and endocrine glands came pre-eminently into the former category, of 'homovital' grafts. 'Homostatic' grafts included those of artery, bone, cartilage and possibly cornea. Grafts of some of these tissues did not even have to be alive on transplantation, but corneal grafts which were dead on transplantation had not given successful results. Dr. Longmire mentioned that plastic substitutes behaved differently from homostatic grafts: they might be tolerated by, but were not incorporated into, the body. Turning to experiments on fundamental problems, Dr. Longmire said that he and his colleagues were engaged with studies on the success of skin transplantation in chicks as a function of age. A small proportion of skin homografts were successful when exchanged between newly hatched chicks of different breeds; but the proportion of successes fell off rapidly to zero by the time the chicks were two weeks old. By holding the age of the recipient constant, it had been found that younger skin had somewhat less power to provoke immunity than older skin.

Dr. J. W. Pate (U.S. Naval Medical Centre) adopted Dr. Longmire's classification of homografts, and said that, inasmuch as certain homografts did not have to be alive on transplantation, their storage in the living state raised unnecessary complications. Some storage treatments entailed chemical modification of the grafted tissue; generally, storage by freezing or freeze-drying was therefore to be preferred. Experiments showed that vitality of arterial homografts was not merely unnecessary but undesirable: frozen-dried arterial homografts were superior to fresh living homografts, and frozen-dried bone was not inferior to living bone. Frozen-dried skin could be used as a homostatic graft for providing a temporary physiological dressing for raw areas on severely burnt patients, in full recognition of the fact that they contained no living cells. Frozen-dried skin was as useful as a living skin homograft for such a purpose.

Dr. W. R. Earle (National Institutes of Health, Bethesda) described his methods for cultivating tissues *in vitro* in large quantities and for long periods. Such mass cultures could be started from single cells grown in capillary tubes, and might be subdivided into sublines which proved to have different properties; nor was growth confined to 'two-dimensional' sheets, for the incorporation of glass helices into the medium provided a framework for solid growth. Dr. Earle had cultivated human skin for 1½ years *in vitro*, and one such culture attained a total area of 1,600 cm.$^2$; he emphasized the tremendous possibilities for research which such materials and techniques now placed at the investigator's disposal.

The second session of the conference was concerned with the problem of storing and grafting endocrine tissue. Dr. Parkes (National Institute for Medical Research) began with a paper by Dr. Audrey Smith and himself on ovarian grafts. Early experimenters, he said, had approached the problem of endocrine homografts with complete disregard of immunological complications, and whether this attitude were wholly justifiable or not, he himself was convinced that endocrine homografts were both practicable and effective. Ovarian tissues impregnated with 15 per cent glycerol in normal saline and slowly frozen to − 190° C. did not deteriorate after a year's storage; when thawed and transplanted into ovariectomized recipients, vaginal œstrous cycles were restored. Rat testes, and probably the pituitary, could be stored in the same way, but the adrenal gland had proved more difficult.

This work was concerned purely with the endocrine activity of stored ovarian tissue; Dr. R. Deanesley (National Institute for Medical Research) considered the degree to which it retained its gametogenic power. Small pieces of ovary from 7-day old rats were frozen and later grafted into older recipients; nearly all the ova had disappeared twenty-four hours later, but healthy follicles could be identified in specimens removed for microscopic examination after 6–10 days. These follicles increased in size with age, and became prematurely luteinized. Similar experiments with frozen testis material showed that it, too, survived such treatment: it remained capable of maintaining histological structure of the seminal vesicles of castrated hosts and gave evidence even of sperm formation.

Dr. P. J. Gaillard (Leyden) recapitulated the results of earlier experiments of his which showed that fœtal tissues could acquire differentiated functional activity if cultivated in media derived from older animals. These experiments opened up the possibility of using endocrine grafts originally derived from fœtuses. Human fœtal parathyroid glands had been maintained in culture for seven weeks, the last stages of cultivation being in media derived from their prospective recipients. The cultivated tissues were transplanted into perivascular tissues of patients who had shown signs of parathyroid deficiency after thyroidectomy. In a number of such patients the calcium and phosphorus levels in the blood were rapidly restored to the normal. Success was more common in the younger patients; all the grafts had failed in patients more than thirty-six years old. Dr. P. F. Jones reported that homografts of adrenal cortical tissue from rats, not more than two days old, could survive in mature adrenalectomized rats of a different strain and could keep their hosts alive for many months. The grafts were well vascularized and looked healthy; their hosts died shortly after the removal of the grafts, so showing that the cortical tissue was actively secreting adequate amounts of hormones.

The third session began with a consideration of the storage of blood. The preservation of even the most labile plasma components, Dr. P. L. Mollison (Postgraduate Medical School) said, was relatively simple. Transfused leucocytes soon left the circulation, so that the principal problem was the preservation of red cells. Red cells can be identified by their antigenic properties; their average life-span was about 115 days. Storage in citrated glucose at 4° C. gave poor results after about a month; maintenance of a $p$H of 7·2 improved the results, and sucrose could be used to delay hæmolysis without, however, improving the survival of red cells after transfusion. Dr. Mollison particularly emphasized the fact that the non-occurrence of hæmolysis or visible abnormality after storage did not by any means guarantee the prolonged survival of red cells after transfusion.

The incorporation of glycerol into storage media made possible the use of storage temperatures far below zero, and therefore storage for long periods; but great practical difficulties were introduced by the need for removing glycerol slowly from red cells stored in bulk. Although there was always some loss of cells on storage at very low temperatures, the deterioration did not increase as storage was prolonged. Dr. Mollison said that transfused red cells sometimes failed to survive, and he wondered whether a reaction akin to that provoked by living nucleated cells could be responsible.

The best rates for freezing and thawing tissues to ensure their survival, and the remarkable protective powers of glycerol, were all discovered and worked out by pure empiricism, sometimes (as with the choice of slow freezing in preference to fast) in the face of expert theoretical advice to the contrary. Dr. J. E. Lovelock (National Institute for Medical Research) considered the biophysical aspects of the process of freezing and showed to what a large extent a reconsideration of the theoretical background of the process had justified the empirical choice of methods. The effect of glycerol was to reduce the range of temperature over which cells were particularly susceptible to damage during freezing; its efficacy depended among other things on its complete non-toxicity, its low molecular weight and free passage across cell membranes; very few other compounds, if any, had just the right combination of properties.

Dr. C. M. Pomerat (University of Texas) had been engaged in an attempt to interpret the behaviour of tissues in bulk during changes of temperature into the responses of individual cells. Apparatus had been devised which made it possible to combine continuous thermal and photographic recordings of cultivated cells—particularly those of human nasal mucosa—under various conditions of thermal stress. The forms of mitochondria and the vigour of intracellular movement were sensitive indicators of a cell's well-being under such conditions. Describing the effects of glycerol, Dr. Pomerat illustrated the vigorous cytoplasmic bubbling consequent upon a rapid transition from glycerol to normal saline solutions. Pinocytosis and nuclear rotation were also illustrated; further study would probably show that these also served as delicate indicators of departures from normality of behaviour.

Dr. R. E. Billingham (University College London) began the fourth session by describing the storage of skin. After impregnation with glycerol solutions, skin slowly frozen to − 79° C. did not deteriorate in any way after even ten-months storage; used as a graft, it was indistinguishable from an unstored normal skin graft in fine structure, colour, epithelial growth-rate, and differentiation of glands and hairs. Such criteria of normality were much more rigorous than those based on mere cellular survival. Melanocytes were much more exacting than Malpighian cells in their storage requirements, and showed up the advantages of using glycerol particularly well. Skin did not survive desiccation from the frozen state below a final overall water content of about 25 per cent; claims that mammalian tissues could withstand a higher degree of dehydration had never been supported by actual estimates of residual water. Glycerol, Dr. Billingham pointed out, was negligibly toxic; even dissociated epidermal cells could withstand being suspended in 98·1 per cent glycerol at room temperature for half an hour.

Dr. F. K. Sanders (University of Oxford) described experiments on the use of nerve homografts. Frozen-dried homografts were capable of guiding regenerating nerve fibres across relatively large gaps in the nerve trunks of small laboratory animals, their endoneural collagenous tubes being systematically re-populated by Schwann cells and fibroblast cells deriving from the host. Fresh homografts elicited a typical homograft immunity reaction in which the vascular stagnation was particularly inimical to successful repair. Results with the use of nerve homografts in human beings had been particularly disappointing. Dr. Sanders argued that this was because the absolute size of such gaps was always larger in clinical practice than in experimental animals; since the time relations of the immunity reaction were not much different in the two cases, and the rate of outgrowth of fibres from the central stump much the same, the difference was probably due to the fact that in human beings the immunity reaction became effective before the regenerating fibres reached the peripheral stump.

The next two papers were concerned with the use of arterial homografts, among the most uniformly successful and rewarding of all those in clinical use. Prof. G. C. Rob and Dr. H. H. G. Eastcott, of St. Mary's Hospital, used normal human vessels, removed as quickly as possible after death and stored in the frozen state. Such grafts gave excellent functional results, the success of which depended neither upon the viability of the graft at transplantation nor upon its length; the new endothelial lining was formed as quickly in long grafts as in short, and they accordingly inferred that it was formed by cells derived from the blood stream and not by creeping invasion from the two ends of the graft. Dr. C. A. Hufnagel (Georgetown University) summarized several years experience with vascular grafts in clinical practice and in experiments with dogs. There was no clinical distinction between the success of fresh, frozen, or frozen-dried grafts, and even frozen-dried heterografts from calves and pigs had given clinically satisfactory results. But even frozen-dried grafts had to be removed and preserved aseptically; experiments still in progress suggested that ethylene dioxide was an efficient sterilizing agent which produced no significant alteration in the fine structure of the grafts.

In clinical practice, transplantation of the cornea must always be of necessity homoplastic, and it is now quite widely known to enjoy an encouragingly high expectation of success. Mr. B. W. Rycroft (East Grinstead) analysed the criteria of success. Mere healing, and even the restoration of translucency, were not enough: there must be improvement of vision, if the graft were done for other than purely cosmetic purposes or to prepare the cornea for a later definitive grafting. Lamellar grafts were safer and generally more successful than full-thickness grafts, in which the danger of infection became serious; but he believed that the optical virtues of the latter might be combined with the safety of the former by means of a 'flanged' graft, or full-thickness centrally but with a thinned rim. Mr. Rycroft believed that corneal grafts were replaced by the tissues of the host; but heterografts were generally unsuccessful, and plastic substitutes inefficacious. One of the chief practical difficulties was over supply. The Corneal Grafting Bill of 1952 had now at last made it possible for eyes to be bequeathed after death, and such eyes might be stored for perhaps two weeks under liquid paraffin; but a method of semi-permanent storage would clearly be of the greatest value.

The proceedings ended with Dr. W. R. Strong's (U.S. Naval Medical Centre) description of the working of the U.S. Naval Tissue Bank, instituted in 1949. The Bank made use of tissues aseptically removed after death and stored after desiccation from the frozen state to less than 1 per cent residual water. Skin, bone and blood-vessels were systematically removed in accordance with an exacting routine and stored after drying in sealed glass vessels. Frozen-dried bone, even in the form of coarse granules, had given encouraging clinical results, and so, in their more limited experience, had blood-vessels. Frozen-dried skin was used purely as a temporary physiological dressing: it relieved pain, controlled the loss of tissue fluids, and reduced the risk of infection.

The impressions left in the mind of one participant were these. 'Homovital' grafts (homografts which must be alive on transplantation and must remain so if they are to serve a useful purpose) are a well-defined category. The use of skin homografts in clinical practice must await a fuller analysis of the methods by which their putative recipients can be made to tolerate them. Such methods have already been discovered; but they are not yet clinically applicable, and it is not likely that anything but fundamental research will make them so. Endocrine homografts sometimes succeed, and treatment of endocrine deficiency by hormones has not yet stolen all the thunder their use might one day cause. At the same time, it would be unfortunate if the dispensation which allows them sometimes to survive where homografts of other tissues fail were not made the subject of thorough scientific analysis; the theory of endocrine homografting as such can at present only be pieced together most incompletely from research conducted with only endocrinological or clinical purposes in mind. Tissue storage will become of practical value when the difficulties of transplantation have been overcome. The storage of skin offers no particular difficulty; nor that of certain endocrine tissues—at least if ambitions fall short of storage in perpetuity. The different endocrine tissues may raise their own peculiar storage difficulties.

'Homostatic' grafts are a less well-defined category. Some must apparently be alive on transplantation, but need not remain so; others may be dead from the beginning; some, perhaps all, provide stimuli for regeneration which could not be imparted by plastic replacements; certainly all require that a certain integrity of fine organization should be maintained. The outlook for frozen-dried arterial grafts is most encouraging, and it may not be too rash to say that the practical problems raised by their storage and use are now in principle solved. Bone homografts, even after freeze-drying, show high promise of surgical use. Corneal grafting, from the nature of things, can only approach asymptotically to 100 per cent success: through no fault of the surgeon, it is at present the only tissue for which storage methods are badly in arrears of methods of transplantation. Scientific workers can help the ophthalmic surgeon by devising efficient storage methods and also by attempting to analyse the occasional failure of corneal homografts after promising beginnings: such failures may prove to be of immunological origin.

# RADIO AND THE CORONATION

CORONATION Day, June 2, was marked by the application of the whole of the modern technique of sound and television broadcasting to enable a vast number of people throughout the world to be in constant touch with the proceedings in London during this eventful day. In the first case, the resources of the B.B.C.'s sound broadcasting service were utilized to the full in providing, for a continuous period of seven hours, a direct commentary on the Queen's Procession from Buckingham Palace to Westminster Abbey, the service and ceremony of crowning in the Abbey, and the subsequent State Procession through London. This programme was provided as an integration of the descriptions given by expert commentators at nine points along the route and inside the Abbey and its Annexe. Apart from the radio transmission, this programme was relayed through loudspeakers to the many thousands of people who lined the route, so that in addition to seeing the procession when it passed them, they could follow by verbal description the entire course of the proceedings.

For the home sound broadcasting service, thirty-seven transmitters were used, with an additional forty-eight stations for the B.B.C.'s external services, by reception from which several hundred local stations relayed the programme regionally in many parts of the world. This involved the use of forty-three languages by the B.B.C. during the day: and furthermore, in order to satisfy the needs for world coverage, the Corporation provided about a hundred positions, with suitable 'effects' microphones, in the Abbey and along the processional route, for the use of other commentators. In this way a continuous and very effective sound picture of the Coronation proceedings was made available to countless millions of people in all parts of the world, and the many congratulatory reports received show that it was greatly appreciated.

## Television

But Coronation Day was also a historic event in the development of television in Great Britain. For the first time in history, not only the State Procession but also the whole of the actual ceremony of crowning inside the Abbey could be seen by millions of viewers all over the country through the television service of the B.B.C. With the aid of five cameras inside Westminster Abbey and several others at various points along the processional route, the television audience was enabled to follow the whole of the day's proceedings. All the television transmitters of the B.B.C. were in use, including the supplementary stations recently brought into service in the neighbourhoods of Belfast, Brighton and Newcastle. In addition to private viewing on domestic receivers, many arrangements were made for the benefit of larger audiences in halls, hospitals and other places. These included the Festival Hall in London, where the presentation of the entire seven-hour programme on a full-size cinema screen was described as excellent, and may be taken to record the arrival of television technique at the stage when it is available for the theatre-going public.

## Television to the Continent

The television service was not, however, confined to viewers in Britain. Following the experience gained last July, when for a week the B.B.C. broadcast part of the daily television programme from Paris provided by Radiodiffusion et Télévision Françaises, this time the British programme was transmitted by a series of radio links to the continent of Europe. In Paris the 405-line signals from London were converted to 441 and 819 lines for re-transmission by the television stations at Paris and Lille; and at Breda, in Holland, arrangements had been made by the Philips organization to convert the British video signals into a 625-line signal. This was then taken by additional radio links to the Eindhoven and Hilversum television transmitters in Holland; and also fed into the permanent network recently set up by the Nordwestdeutsche Rundfunk to link up the five or six television stations of that administration in Western Germany, including Berlin. The accompanying sound programme was transmitted independently by cable to the Continental organizations, where either the English language could be used or this could be translated by local commentators. This enterprise for the international relaying of television programmes has met with unqualified success. Tens of thousands of French people saw the Coronation ceremonies on television screens either in private houses or in the many windows and booths in Paris where television receivers had been set up in shops and newspaper offices.

## Service to North America

The technique of the subject has not yet advanced to the state where a direct television service can be established across the Atlantic to the vast potential numbers of viewers in North America on such an occasion as this. Careful examination had been made during the past year or more of proposals to relay the vision signals from high-flying aircraft or over a series of radio links, but even the vast resources of the United States broadcasting organizations could not render this a practical means of getting a direct 'live' view of the Coronation proceedings. An attempt was made in New York to receive the British television signals by direct transmission, but nothing suitable for introduction into the American television service was obtained. Failing this, the most rapid means of letting American viewers see the proceedings in London was by facsimile or photo-telegraphy transmission. Within twenty minutes of the crowning of Queen Elizabeth, pictures of the scene in Westminster Abbey were being sent direct from London into newspaper offices throughout the United States; and these pictures were transmitted over the television networks, so that millions of people throughout the United States could follow the ceremonies with the aid of the service of the B.B.C., which according to *The Times* correspondent "was received with unfailing power and clarity".

Furthermore, as the next best substitute to a 'live' television service, the two major American broadcasting networks (National Broadcasting Company and Columbia Broadcasting System) had Coronation films flown across the Atlantic in a Canberra bomber to Newfoundland, where other aircraft were waiting to take the films on to distribution points in the television networks of Canada and the United States. In this way viewers in North America were, owing to the difference in local times, enabled to have their own view of the Coronation proceedings on the same afternoon as the events took place in London.

### General Appreciation

In one respect only does television technique on a public service basis lag behind the possibilities of the cinematograph film. The pictures are still presented in black-and-white, whereas anyone who witnessed the actual State procession will agree that the pomp and splendour of this could only be given an adequate appraisal by a presentation in full colour. In spite of this limitation, however, the radio correspondents of the daily Press have had nothing but praise and glowing terms of appreciation for the magnificent service given by the B.B.C. and all those connected with this organization, for an outstanding achievement in the history of broadcasting and television.

On the technical side, some thirteen hundred additional sound circuits and more than a hundred vision circuits in and around the London area were provided by the Post Office Engineering Department, working in co-operation with the B.B.C. engineers. It is probable that only those closely connected with the technical and programme sides of broadcasting can appreciate the immense complexity of the circuit and other arrangements necessary to collect together such magnificent programme material and disseminate it to the entire satisfaction of the recipients, public and private, all over the world.

Whatever may be the future of British broadcasting, there is no doubt that, on this occasion, the B.B.C. lived up to the reputation, acclaimed by many, of presenting the best public broadcasting and television service in the world.

# NEWS and VIEWS

### Physical Chemistry at Manchester:
### Prof. Geoffrey Gee, F.R.S.

PROF. GEOFFREY GEE, who has recently been appointed to the chair of physical chemistry in the University of Manchester in succession to the late Prof. M. G. Evans, was born at Disley, Cheshire, and received his early education at New Mills Grammar School under the headmastership of Mr. W. A. Whitton. In 1928 he entered the Honours School of Chemistry in the University of Manchester under Prof. Arthur Lapworth; here he obtained the B.Sc. and M.Sc. degrees and did two years work on electrocapillarity in the Thomas Graham Colloid Research Laboratory. In 1933 he joined the staff of the Dyestuffs Group of Imperial Chemical Industries, Ltd., and for five years he worked in the Department of Colloid Science at Cambridge in association with Sir Eric Rideal and later with Prof. H. W. Melville. During this period, alone or in collaboration, he published more than a dozen papers of a pioneering type on two main topics—oxidation and polymerization reactions in monolayers, and the kinetics of polymerization in the liquid phase. In 1938 he joined the British Rubber Producers' Research Association, and in 1947 he was appointed director of research in the Association. His publications in this period deal with olefin oxidation and, more especially, with the thermodynamics of polymer systems, in which subject, again, he did pioneer work which has led the way to a closer relation of thermodynamic properties to macro-molecular structure. Prof. Gee was elected a Fellow of the Royal Society in 1951 and in 1952 was awarded the Colwyn Medal by the Institution of the Rubber Industry. His return to his old University is warmly welcomed, especially by those who remember him there in his student days.

### Mathematics at Dundee

PROF. A. M. MACBEATH has been installed in the chair of mathematics at University College, Dundee (University of St. Andrews). Prof. Macbeath, who is twenty-nine, was educated at the Royal Academical Institution, Belfast, the Queen's University of Belfast and Clare College, Cambridge. Graduating with first-class honours in mathematics at Queen's in 1943, he served from then until the end of the War as a junior administrative officer in the Foreign Office. At Cambridge he was a Wrangler in Part 2 of the Mathematical Tripos in 1946 and gained a mark of distinction in Part 3 in the following year. After a year's research at Cambridge on the geometry of numbers, he was awarded a Commonwealth Fund Fellowship in 1948. With this fellowship he continued his researches in number theory for two years at Princeton University, obtaining the degree of Ph.D. in 1950. On his return to Cambridge he was elected to a fellowship at Clare, where he worked until October 1951; he was then appointed to a lectureship in mathematics at the University College of North Staffordshire. In the following year he was promoted senior lecturer and played a major part in framing the courses in pure mathematics in the new College. Prof. Macbeath's contributions to pure mathematics are already substantial, and there is no doubt that he will add to them during his tenure of the chair at Dundee.

### Everest

ONE of the great challenges to the spirit of human endeavour in the field of exploration and determination to beat natural obstacles was overcome on May 29, when E. P. Hillary, of New Zealand, and Sherpa Tensing Bhutia, of Nepal, had successfully reached the summit of Mount Everest. This fine achievement by the members of Colonel H. C. J. Hunt's expedition is a noteworthy climax to a long series of attempts dating from the reconnaissance of 1921, and, with the news coming on the eve of the Coronation, the British people can take more than especial pride that their country has engineered this success. However, mountaineering, like science, is not a purely national affair, for it is practised by many peoples and, like science again, builds on the successive experience and knowledge gained by previous generations. First of all, tribute must be paid to the Sherpa porters, without whose courage and endurance this year's expedition—and all the previous ones—could never have started at all; to them, too, falls the honour that one of their number made the final assault. The route followed this year is the comparatively new one from the south, first reconnoitred by Mr. Eric Shipton's party in 1951. The pre-war attempts were all on the northern side by way of Tibet, but that country is now closed to foreigners whereas, paradoxically enough, Nepal, which previously had been a forbidden country, now permits the passage of expeditions. The favourable reports of Mr. Shipton encouraged a Swiss team to make a serious attempt last year, and they were almost successful, for M. Raymond Lambert and the same Sherpa Tensing got within 800 ft. of the summit. It is a great tribute to the Swiss party that, in the true spirit of mountaineering brotherhood and international co-operation, so characteristic of their country, they imparted all the hard-earned details of their climb to this year's expedition.

Finally, mention must be made of the part science and technology have played. It is no belittlement of the prowess of the climbers to say that without oxygen they would never have succeeded, and this year has seen the improvement of the 'open-circuit' oxygen apparatus and the novel development of a 'closed-circuit' apparatus; incidentally, it has been reported that the first assault with the latter type was unsuccessful and that Hillary and Tensing, who were the second pair to make the attempt, used 'open-circuit' masks. Then again, the developments during the past decade and more of synthetic materials, and the experience gained of the physiology of human exposure and acclimatization, together with other recent advances of science and medicine, have all played their part. Nevertheless, any expedition reduces in the end to a battle between man and Nature, and rash indeed would he be who would prophesy that in future man will always be the victor.

It has since been announced that Mr. Hillary has been made K.B.E. and Colonel Hunt has been created a knight; Sherpa Tensing is not a British subject and the question of recognition of his achievement is under discussion.

## The Wiles Lectures at Queen's University, Belfast

THE Queen's University of Belfast has received a gift of £7,500, to be spent over the next 7–10 years, to promote the study of the history of civilization and to encourage the extension of historical thinking into the realm of general ideas. The gift is from Mrs. Austin Boyd, of Cultra, Co. Down. It is to be used to endow an annual series of about four lectures, to be known as the Wiles Lectures, in memory of Mrs. Boyd's father. The purpose of the endowment is not to popularize history, but rather to invite a few historians of distinction to reflect on the wider implications of their work, and to embody their reflexions in the lectures and in a book. It is hoped that the Wiles Lectures will bear fruit in two ways: on one hand by encouraging some younger historians to enter the difficult field of research into the history of ideas; and on the other hand, by broadening eventually the basis of the teaching of history in schools, so that more emphasis is put on supra-national than on national movements. The benefactress hopes to make a further gift to the Queen's University so that the purpose of the endowment may be continued beyond the experimental period of 7–10 years. In administering the endowment the Queen's University will be advised by a committee including its own professor of modern history, together with two scholars to be invited from other universities.

## Natural Gas in Britain

AT a recent meeting of the Institution of Gas Engineers, Sir Harold Smith, chairman of the Gas Council, stated that an intensive, large-scale search for natural gas in Great Britain is to begin in the near future. The supply of good gas-making coal is decreasing and becoming more difficult to win, and therefore every possibility of developing methods of using coals normally considered unsuitable for carbonizing by orthodox means should be considered; further, the efficiency of existing carbonizing processes should be improved. But this is not enough, for the urgency in these matters is dictated by rapidly increasing cost of coal, and it is necessary that investigation into new supplies of gas from natural sources should be undertaken. In co-operation with the Anglo-Iranian Oil Co., Ltd., the Gas Council is proceeding with a scheme of exploration for natural gas in Britain estimated to last about five years. No rosy vista of commercial success can be envisaged, judged by past records, of which Heathfield, Sussex, is the classic example. None the less, a search sufficiently wide and deeply spread in Britain will at least settle once and for all this controversial problem of the occurrences of natural gas, and to this extent the scheme appears justified.

## Glass in Chemical Industry

GLASS has for many years held pride of place in the field of laboratory apparatus, and in recent years its use is being extended to chemical industrial plant where the dimensions are on a very much larger scale. For the supply of laboratory glassware (mainly heat-resistant borosilicate glass) a well-known name is Quickfit and Quartz, Ltd., a firm which has built up a reputation in the manufacture of ground-glass standard interchangeable conical joints, whereby complicated pieces of apparatus can be built up from a relatively small number of standard components. The firm started before the Second World War at King's Norton, near Birmingham, and in 1946 transferred most of its work to Stone in Staffordshire (see *Nature*, 164, 907; 1949). Production at Stone is now in full swing.

The latest developments at Stone are mainly in the field of large pieces of glassware, and one of the most interesting processes that has recently been put into operation is the electric welding of large joints. Though this process is well known in the United States, where electricity is much used and the gas industry is small and, being based on natural gas, is not suitable for glass-working, the method has only been recently introduced into Great Britain. The method is at present only suitable for joints of a simple shape, such as putting on the neck of a flask, but the dimensions can be relatively big (for example, 20–30 cm. diameter). The two parts to be joined are mounted on a glass-working lathe, brought almost together and rotated between electrodes placed at opposite ends of a diameter. The electrodes are hollow and carry small gas-flames which heat up the glass and thereby reduce its electrical resistance from the order of megohms to thousands of ohms. The current is then switched on from a 120-kc./s. generator of 25 kVA. output. The current passes over the small gaps from the electrodes and flows through the glass, heating it uniformly through the body of the work but at the same time over an annular volume that is very narrow. The power factor is usually 0·5–0·8, and when the joint is made and the glass molten the current is about 3 amp. at about 10 kV., some 12 kW. being dissipated in the glass. The frequency of the generator is not critical; but at 120 kc./s. the voltage can only burn and not electrocute in the event of an accident to an operator. The main advantage of this method is the uniform heating through the glass and the small volume of heating as compared with large gas-flames, which heat only on the surface and over a wide area, and for electric-welded joints the subsequent annealing process (which is very time-consuming) is much easier.

## Radiophysics Laboratory, Sydney

One of the Divisions of the Commonwealth Scientific and Industrial Research Organization of Australia is the Radiophysics Laboratory, situated in the grounds of the University of Sydney, and the chief of the Division is Dr. E. G. Bowen. The four main fields of research in the Laboratory are radio astronomy, cloud and rain physics, automatic computation and the development of radio aids to navigation, and in a very attractive and well-illustrated brochure, entitled "Research Activities of the Radiophysics Laboratory" (pp. 36. Melbourne: C.S.I.R.O., 1952), a brief account is given of the Laboratory's current work under these four separate headings. The section on radio-astronomy is mainly concerned with the study of radio noise from the sun and outer space. The design of a new solar radio-spectroscope, now under construction, which is to cover the frequency-range 40–240 Mc./s., and a 32-element interferometer, which will be used at decimetre wave-lengths for the location of sources of solar radio noise, are described. Investigations to determine the positions and characteristics of discrete sources of cosmic noise and the techniques involved are discussed, and an interesting study is outlined of the temperature and structure of the ionospheric *D*-layer by an application of a method first used in radio astronomy to measure the thermal emission from the solar corona. The study by micro-wave radar of rain formation and cloud-seeding experiments for rain-making are the main items in the rain and cloud physics section, and details of the binary type Mk. I digital computer which has now been in use for about a year are given in the section on automatic computation. In the final section, dealing with radio aids to navigation, are described two short navigational aids, the "Distance Measuring Equipment" for aircraft and the "Multiple Track Range" providing a number of flight tracks to and from an airport, and, in addition, a recently developed micro-wave direction-finding apparatus operating at a wave-length of 3·2 cm. The accounts of the work of each section are terminated by a detailed list of scientific papers published by its members during 1948–52.

## Imperial College of Science and Technology, London: Report for 1951–52

The forty-fifth annual report of the Governing Body of the Imperial College of Science and Technology, London, covering the year ended July 31, 1952 (pp. 60; from the College, 1953), refers to the start being made on the new building for the Aeronautics Department, although the steel allocation was at that time being awaited. The creation of laboratories for mineral dressing in the Bessemer Laboratory was nearing completion and a small extension of the Department of Metallurgy was being made in the same building. The space available for expansion in the South Kensington area has been increased by purchase of the freehold of the property at 179 Queen's Gate, and an additional twenty-eight acres of land contiguous to the Field Station at Silwood Park, Sunninghill, have also been purchased. A series of lectures on general subjects for first-year undergraduate students was organized by the Dean of the City and Guilds College during 1951–52, and, with the London School of Economics and Political Science, joint postgraduate studies in technology, economics and administration have been arranged for the session 1952–53. As a further experiment in co-operation between academic staff and students, the College hours are being varied so as to leave two hours (12.30 p.m.–2.30 p.m.) on Tuesdays and Thursdays entirely free from organized College studies. On each of these days a joint committee of staff and students is arranging functions such as discussion talks by outside experts, concerts of chamber music and general entertainments organized by student societies. Besides the statement of accounts and details of teaching and administrative staff changes, appendixes to the report include a list of publications during 1951–52, arranged under departments.

## Dry Rot in Wood

A fifth edition of "Dry Rot in Wood", Bulletin No. 1 of the Forest Products Research Institute, by K. St. G. Cartwright and Dr. W. P. K. Findlay, has been issued under the auspices of the Department of Scientific and Industrial Research (pp. 36+8 plates. London: H.M.S.O., 1952; 2*s*. net). It is said that dry rot has become very much more prevalent during the past decade, though whether this is so has not been proved; nevertheless, there must be many people who are acquainted with the appearance of dry rot in the house in floor-boards and other woodwork. The attack is caused by ***Merulius lacrymans***; moisture is necessary, and strands of the fungus can transport the moisture so that it can rot moderately dry timber once it has got a hold. Dry rot spreads easily. Like the white ant of the tropics in its search for timber, the fungus is said to be able to pass through brick or stone walls via the mortar. As to methods to combat it, the council of perfection is to have no damp spot anywhere in the house. "Leaky gutters, cracked pipes and so on should be repaired immediately. Cellars should be kept dry." Are all these precautions possible these days? There is often a considerable delay before repairs to leaking roofs, pipes, etc., can be effected, and, though it may be feasible to keep a small cellar dry, in country houses where the cellarage may be of fair size it would be very expensive to keep them heated throughout the winter; and, in the case of the wine cellar, the cherished wine would be ruined. Nevertheless, this edition of the bulletin has been thoroughly revised, and in houses of any size it should be regarded as indispensable. No simple practical remedial measure is apparently yet available.

## Metals in the Service of Man

In the ***Museums Journal*** of May 1953, Mr. A. R. Hutchieson describes the modern treatment of the non-ferrous metals at the Royal Scottish Museum, Edinburgh. This has been arranged as a panorama of metals in the service of man. Beginning with a brief survey of their discovery and early uses, this is followed by an attractive introduction to the more technical exposition of modern extraction methods, processing and applications. Bold, colourful maps and diagrams are used, and by an imaginative selection of characteristic three-dimensional material the display has atmosphere and life. Aluminium, magnesium, nickel, copper, tin, lead and zinc have been dealt with, and the growing popularity of the new display with visitors indicates that the method of presentation has been successful.

## Deep-Sea Floor and the History of the Earth

A symposium on the "Deep-Sea Floor and the History of the Earth" has been arranged by the International Joint Commission on Oceanography of the International Council of Scientific Unions and will be held at the University of Liverpool during September 1–2 immediately preceding the meeting of the British Association. The International Union of Geodesy and Geophysics and the International Union of Biological Sciences are represented on this Commission, the constitution of which is as follows: *President*, J. D. H. Wiseman (Great Britain); *Secretary*, C. D. Ovey (Great Britain); *Members*, A. F. Bruun (Denmark), C. W. Correns (Germany), L. Fage (France), Ph. H. Kuenen (Holland), H. Pettersson (Sweden), R. Revelle (United States), Mary Sears (United States); *Advisory Councillors*, F. Bernard (Algeria), F. Koczy (Sweden), J. D. Nares (representing the International Hydrographic Bureau), J. Rouch (Monaco), H. U. Sverdrup (Norway), H. C. Urey (United States) and C. E. ZoBell (United States). The main object of the Commission is to stimulate international collaboration in fundamental research on deep-sea problems, through recent developments in electronics, physics, chemistry and biology, combined with technical advances in detailed surveying and sampling of the deep-sea floor, which have made possible a new level of scientific understanding of the deep sea.

## Merck Fellowships of the Canadian National Research Council

Three post-doctorate research fellowships, endowed by Merck and Co., Ltd., have been awarded by the National Research Council, Ottawa. The awards, which total 11,000 dollars and travel allowances, with an extra 500 dollars to each institution concerned, to help pay for specialized equipment, have been made to the following for research as indicated: Dr. W. G. B. Casselman (Universities of British Columbia and Toronto), cellular physiology, at the University of Oxford, under Dr. J. R. Baker; Dr. G. D. Fasman (University of Alberta and the California Institute of Technology), alkaloids and nucleosides, at the Technische Hochschule, Zurich, under Prof. V. Prelog; Dr. B. A. Gingras (University of Montreal), reactions of free radicals in solution, at the University of Oxford, under Dr. W. A. Waters.

## Association of Applied Biologists

The officers and council for 1953–54 of the Association of Applied Biologists is as follows: *President*, Prof. W. Brown; *Vice-Presidents*, Mr. R. W. Marsh and Prof. J. B. Cragg; *Honorary Treasurer*, Dr. H. F. Barnes; *Honorary General Secretary*, Dr. R. K. S. Wood (Imperial College of Science and Technology, London, S.W.7); *Honorary Programme Secretary*, Dr. L. Broadbent; *Honorary Editor of the Annals of Applied Biology*, Mr. R. W. Marsh; *Honorary Assistant Editor*, Dr. I. Thomas; *Council*, Dr. P. W. Brian, Dr. C. H. Cadman, Prof. J. B. Cragg, Dr. D. W. Fenwick, Dr. R. M. Greenslade, Dr. I. Isaac, Dr. W. F. Jepson, Dr. M. A. Keay, Dr. A. H. McIntosh, Mr. B. D. Moreton, Dr. I. W. Prentice and Dr. A. F. Posnette. The Association celebrates in 1954 the fiftieth anniversary of its founding, and to mark the occasion a series of special meetings will be held during September 13–17, 1954, to which a number of distinguished scientific workers from overseas will be invited. A jubilee fund for the expenses of this meeting was started in December 1952; further contributions to this fund should be addressed to the treasurer of the Association.

## University of London: Appointments

The following appointments in the University of London have recently been announced: Dr. G. O. Jones, reader in experimental physics at Queen Mary College, to the University chair of physics tenable at that College; and Dr. W. B. Pennington, research Fellow at Jesus College, Cambridge, to the University readership in mathematics tenable at Westfield College. The title of reader in mathematics in the University has been conferred on Dr. C. A. Rogers in respect of the post held by him at University College, London.

## Announcements

Sir John Russell, formerly director of Rothamsted Experimental Station, has been elected a foreign member of the Finnish Academy of Science and Letters.

M. Philibert Guinier, director of the École des Eaux et Forêts, Nancy, and *correspondant* for the Section of Rural Economy of the Paris Academy of Sciences, has been elected a member of the Section in succession to the late Prof. L. Lapicque.

The Institute of Fuel has awarded its Students' Medal and Prize for 1952 to B. H. Holland, of the Department of Coal Gas and Fuel Industries with Metallurgy, University of Leeds, for his paper on "The Structure and Stability of Flat Burner Flames".

Dr. David R. Goddard, professor of botany in the University of Pennsylvania, has been elected editor-in-chief of *Plant Physiology*, the journal of the American Society of Plant Physiologists.

The Committee of Privy Council for Agricultural Research and Nature Conservation has re-appointed Lord Rothschild as chairman of the Agricultural Research Council for a further term of five years. It has also approved the appointment of Prof. Stephen J. Watson as deputy chairman of the Council.

Mr. R. C. Worster, who has been a member of the research staff of the British Hydromechanics Research Association since its formation, has been appointed deputy director of research in the Association.

The following have been appointed lecturers in the University of Leeds: F. P. G. Whitaker (industrial administration in the Department of Economics), Dr. F. S. Trippett (organic chemistry), and T. J. Bowen (biochemistry).

The Challenger Society is prepared to consider applications for small grants in aid of research in marine biology or oceanography at a recognized laboratory during the year June 1953–June 1954. Applications, accompanied by details of the proposed research, should reach the honorary secretary, Mr. N. B. Marshall, British Museum (Natural History), London, S.W.7, before the end of June.

Erratum. In the communication "Difference between the Density Distribution of Neutrons and Protons in Atomic Nuclei" (*Nature*, May 30, p. 979), paragraph 2, line 8, for "$1+b(r/r_0)^2$" read "$[1+b(r/r_0)^2]^2$".

# PHYSICS OF THE SOLID STATE

## PHYSICAL SOCIETY SPRING MEETING

THE spring meeting of the Physical Society was held in the Physics Department of the University of Leeds; the president of the Society, Prof. R. Whiddington, was in the chair. The meeting was devoted to several topics under the general heading of "Some Aspects of Solid State Physics" and was well attended, some hundred and eighty people being present.

Introducing the first session, "The Analysis of Magnetization Curves", Prof. E. C. Stoner (Leeds) related such curves with the general characteristics of ferromagnetics and the main processes by which change of magnetization may occur; these latter are changes in intrinsic magnetization, rotation of domain magnetization vectors and movement of domain boundaries. Much is now known of these processes individually, but the statements made about their relative contributions to a change along a magnetization curve of an ordinary polycrystalline material are little more than plausible guesses. By an 'analysis of magnetization curves' is understood a determination of the processes taking place; this can be achieved by a suitable combination of experimental measurements and theoretical reasoning. Measurements of the reversible susceptibility, together with the ordinary magnetization curve, enable the reversible and irreversible contributions to be separately determined. Investigation of the thermal changes accompanying adiabatic magnetization, on appropriate analysis, gives a quantitative indication of the contributions from the various elementary processes. The analysis can be made more nearly complete if that part of the thermal change associated with the reversible processes can be separately determined; this is possible by an indirect method recently developed. Further experimental work will be necessary before complete analyses are possible; but from partial analyses already made it appears that the main thermal effects are usually due to rotations and changes in intrinsic magnetization. The magnetic and thermal changes in moderate and, to a large extent, in low fields can be satisfactorily co-ordinated, but the detailed interpretation of the behaviour in high fields presents greater difficulties.

Prof. L. F. Bates (Nottingham) then gave a description of the method of measuring small temperature changes accompanying the magnetization of ferromagnetic rods in low and moderate fields. Examples were given of earlier measurements and their interpretation in terms of the Stoner and Rhodes theory in which the thermal changes due to the so-called magneto-caloric effect are subtracted from the observed changes and the differences used to calculate an important coefficient. Prof. Bates discussed the values of this coefficient for many metals and alloys, and showed some results for cobalt in which the reversible and irreversible thermal changes had been separated in a simple manner and the coefficient again calculated. Measurements on a 'Ferroxcube' rod were described, and these showed that the thermal changes accompanying magnetization were in this case almost entirely due to changes in intrinsic magnetization. Finally, he compared the results of high field measurements on 'Alnico' with the theory given by Rhodes of the heat changes in an idealized ferromagnetic of high coercivity.

An account was given by Dr. R. S. Tebble (Leeds) of the separation of the processes involved in the magnetization of a ferromagnetic at low fields from measurements on the reversible change in magnetization with temperature. The contributions of rotations of the magnetization vectors, and changes in intrinsic magnetization, have been estimated for annealed nickel, and it is probable that the effect of boundary movements can also be estimated. The agreement in high fields with the measurements of Bates and Davis was shown by Dr. Tebble to be good. He suggested that, if the appropriate measurements can be made on one specimen under carefully controlled conditions, it should be possible to extend this work to a separation of the reversible and irreversible components of the magneto-caloric effect.

Prof. W. Sucksmith (Sheffield) stated that the magneto-caloric effect in high fields probably constitutes the most useful and reliable method for tracing the variation of spontaneous magnetization with temperature and has only been applied fully to the case of nickel. A method of measuring the small rise of temperature with adequate accuracy has been developed. The experimental results for copper–nickel alloys have established a new feature in the non-linear relation between the rise of temperature and the square of the magnetization above the Curie temperature, while the tail of the spontaneous magnetization curve attributed to fluctuations by some writers is certainly not greater than for pure ferromagnetics; in the case of ferrites it becomes almost non-existent.

Mr. K. L. Hunt (Leeds) described a mathematical extension of the collective electron theory of ferromagnetism in which the energy associated with the magnetization is taken not simply as proportional to the second power of the magnetization but as dependent on both the second and fourth powers. A further adjustable parameter is thus introduced. A high degree of co-ordination may then be obtained between all the observed magnetic and thermal properties of nickel and of some nickel alloys. The change of magnetization with field in high fields is the single property for which a qualitative account only is possible. There are indications, however, that this change of magnetization is not entirely that of the intrinsic magnetization, even in high fields.

The next session, on "The Band Theory of Metals", was introduced by Prof. H. Jones (London), who gave a critical survey of the three main assumptions on which the theory is based. These are: (1) the Hartree–Fock self-consistent field method which implies that each electron is in a stationary state, the total wave function being written as a single Slater determinant of the one-electron functions; in consequence the total energy may be written as the sum of the one-electron energies together with an interaction term; (2) the interaction term is independent of the distribution of the electrons over the available states, implying that the electrons may be treated by Fermi–Dirac statistics; and (3) the one-electron functions may be expressed as the product of a space function and a spin function. In conclusion, Prof. Jones stressed the importance of calculations of basic characteristics of particular metals; these would enable the logical consequences of the assumptions to be compared with experiment and the adequacy of the assumptions tested.

Dr. E. P. Wohlfarth (London) gave an account of an approximate treatment to determine the form of the total energy for a metal, the Bloch tight-binding approximation being used for the calculation. For infinite separation of the atoms, this approximation leads to the correct expression for the total energy when the spins of all the electrons are parallel; but when there is zero resultant spin moment, there is a large additional term in the energy expression. Dr. Wohlfarth suggested that, as a first approximation, this large correlation term could be treated as independent of interatomic distance when the dependence of the total energy on the number of electrons per atom and the magnetization could be estimated. He then related the results of this treatment to the analyses of Mr. K. L. Hunt. The applicability of Fermi–Dirac statistics to electrons in metals was also discussed, and he suggested that this provides a good approximation at least for those electrons which can be treated by means of the tight-binding approximation.

Experimental work on the transition elements, directed to the elucidation of their band structures, was then described by Dr. F. E. Hoare (Leeds). Starting with the simple picture of an incompletely filled *d*-band overlapped by an *s*-band, it is to be expected that alloying the appropriate neighbour of higher atomic number should fill the *d*-band at a particular concentration, the alloy then becoming diamagnetic. Alloying with a neighbour of lower atomic number should, on the other hand, create more holes in the band. The height of the band should vary in these alloying processes, and measurements of the electronic heats of the alloys will show the manner of this variation. The experimental results for the susceptibilities of palladium–silver and palladium–rhodium alloys were shown by Dr. Hoare, along with the electronic heats of palladium–silver, and the qualitative agreement with the simple band picture was discussed. The marked difference in behaviour of the electronic heat in the palladium–silver and nickel–copper systems was indicated. Preliminary results for the susceptibilities of the platinum–gold and platinum–iridium systems were shown, and it appears that these may be interpreted in the same general scheme as the former results.

Dr. P. Rhodes (London) discussed the dependence of the temperature variation of paramagnetic susceptibility and electronic specific heat on the form of the density of states relation. He showed how earlier treatments assuming simple band forms have led to the conclusion that the paramagnetic susceptibility is a monotonically decreasing function of temperature, whereas more recent experimental results for palladium and certain of its alloys with silver show that the susceptibility/temperature curves may exhibit maxima. Results for the low-temperature specific heat of the palladium–silver alloys indicate that the band form in palladium is not of the form assumed in the earlier treatments. When the treatment is developed using a band form appropriate to that derived from the experimental results, the calculated susceptibility/temperature curves do, in fact, exhibit maxima. A brief account was also given of some effects of band overlap and band closure.

A short description of the dependence of the steady (field independent) diamagnetic susceptibility of metals and alloys on their electronic structure was given by Mr. E. W. Elcock (Leeds), who indicated how the earlier treatments are inadequate to explain the complicated dependence of susceptibility on temperature and composition for alloys of polyvalent metals. He showed how, by a straightforward extension of these earlier treatments, it is possible to correlate effects of both temperature and alloying on the susceptibility. The alloys of bismuth with small concentrations of lead and tellurium were particularly considered, and the bearing of the treatment on a wider range of metals and alloys was indicated. Finally, Mr. Elcock suggested a possible interpretation of the curious oscillatory character of the temperature variation of the susceptibility of zinc in terms of the treatment developed.

In introducing the final session, on "Luminescence and Ferroelectricity", Dr. J. H. van Santen (Philips Research Laboratories, Eindhoven) reviewed the properties of pure and perfect non-metallic solids in terms of simple band theory. Impurities and imperfections modify these properties by introducing localized energy-levels. In elements such as germanium and silicon the type of semi-conductivity, *p* or *n*, depends on the valency of the impurity relative to that of the host. In alkali and silver halides the introduction of divalent ions leads to increased conductivity through the production of cation vacancies. In oxides, however, the impurity may also produce changes of valency in some of the host cations; for example, $(1-\delta)$ NiO with a small amount, $\delta/2$, of $Li_2O$ can be represented as

$$Li_\delta Ni^{2+}_{1-2\delta} Ni^{3+}_{\delta} O^{2-}$$

and has a *p*-type conductivity. Kröger has shown that gallium in zinc oxide can produce cation vacancies, change of valency of some zinc ions in a reducing atmosphere, leading to *n*-type conductivity or, under oxidizing conditions, to holes trapped near cation vacancies giving *p*-type conductivity. He considers that the blue luminescence of self-activated zinc sulphide is associated with the third kind of centre.

Dr. E. E. Schneider (King's College, Newcastle) gave an account of the mosaic structure of single crystals, citing evidence obtained from optical scattering that the size of the blocks is about 2000 A. He then surveyed the types of defects in crystals, with particular reference to Seitz jogs, which are considered to act as incipient vacancies. Discussing colour centres, he directed attention to the new colour-centre model of Kittel and Kahn in which an electron is regarded as being shared by the six negative ions surrounding the vacancy. This makes the *F*-centre similar to the *V*-centre, in which a positive hole is shared by six anions around a positive ion vacancy. Other *F*- and *V*-centres must exist and probably consist of simple aggregates of simple *F*- and *V*-centres and vacancies. Information on vacancies can be obtained from conduction measurements. Recent work by Cunnell on conductivity and polarization effects gives strong support for the mosaic idea and suggests that at low temperatures the positive ion vacancies are held at or near block boundaries. Coloration must include a mechanism which frees vacancies from boundaries. The build-up of *F*-centres under X-radiation, an initial steep portion with high efficiency followed by a less steep portion leading to saturation, is attributed to an initial easy release of vacancies from boundaries followed by a less efficient release from Seitz jogs. Cunnell's work shows that a coloured crystal displays a small conductivity with increasing temperature, an increase in the temperature-range of bleaching and the maintenance of this increased conductivity on cooling.

Mr. J. Ewles (Leeds) gave an account of investigations, recently completed at Leeds, into the optical and electrical properties of phosphors. He pointed out that luminescence is not a rare phenomenon in solids but is likely to accompany imperfections in crystals whether these are caused by impurities or by thermal treatment. It is, in fact, rarely absent in real crystals, being suppressed only with extraordinary purity and in the absence of thermal strains. It can be intensified by sudden quenching, and reduced or removed by annealing. Recent experiments carried out by Lee have led to a modification of the theory of the large centre first introduced by Ewles in 1930. The modified theory now takes into account the competition of structure centres provided by imperfections, and is in good agreement with experiment. Further, it permits the evaluation of the size of the centre. Mr. Ewles also gave a brief account of the remarkable optical and electrical properties of some new oxygen-activated alkali halide phosphors investigated by Barmby. These phosphors show sharply resolved luminescent bands which must be attributed to oxygen ions adsorbed on the halide. The luminescence is accompanied by very large increases in conductivity. Thermoelectric powers up to some two millivolts per degree indicate that the conduction is electronic, and an interpretation in terms of the effect of the adsorbed oxygen on the band levels of the halide crystals was given.

In the section on ferroelectricity, two papers were presented: the first, by Dr. L. E. Cross, on ferroelectricity in the perovskite type structures; and the second, on the theory of ferroelectrics, by Dr. A. F. Devonshire.

Dr. Cross (Leeds) directed attention to the importance of accurate measurement of electric hysteresis in the ferroelectric state. He described the method normally used for measuring the hysteresis, and examined the limitation imposed by the electric conduction through the ferroelectric. After a brief description of the perovskite structure, he listed the minerals which are of interest electrically and, from them, examined in more detail barium titanate, potassium niobate and sodium niobate. The sequence of symmetry changes which occurs on cooling barium titanate was described by Dr. Cross, and the electric domain structures occurring in the tetragonal room-temperature phase examined, new evidence being produced to confirm the existence of a system of anti-parallel domains within the individual twin unit. Hysteresis figures obtained on untwinned barium titanate crystals above the ferroelectric Curie temperature were shown, and these were compared with previous results in the United States. New measurements of electric hysteresis effects in potassium and sodium niobates were also reported. In the potassium salt, the results were shown to be in reasonable agreement with previous work. Preliminary results on sodium niobate, however, have revealed a linear dielectric up to field-strengths of 20 kV./cm., and clearly this is not a normal ferroelectric.

Dr. Devonshire (Bristol) said that he would consider only the theory of the single domain. This theory can be divided into two parts: first, the purely thermodynamic theory of the relations of the elastic, piezoelectric and dielectric constants to each other; and second, the relation of these to the atomic structure. It is important to carry out a thermodynamical analysis of experimental results, before devising a detailed atomic theory. This analysis shows that all the anomalies observed at the transition temperature are due to the fact that the dielectric stiffness coefficient tends to zero at this point; Dr. Devonshire also suggested that the first-order character of the transition in barium titanate is probably due to the interaction between strain and polarization. The smallness of the dielectric stiffness coefficient is due largely to electrostatic interaction between the different parts of the polarized medium; this is in contrast with ferromagnetic materials, for which magnetostatic interaction is of small importance. The temperature variation is due to the higher entropy of the unpolarized state. The existence of a lower transition in Rochelle salt is probably due to the existence of a stable anti-parallel arrangement of dipoles below this temperature.

The meeting provided a welcome opportunity for an exchange of views among those working in related fields, and full advantage was taken of this in a number of extended informal discussions.

F. E. Hoare

# OXIDATION OF OILS AND FATS

A SYMPOSIUM on "Oxidation" was held by the Oils and Fats Group of the Society of Chemical Industry in the Low Temperature Research Station, Cambridge, on April 24. Prof. T. P. Hilditch, chairman of the Group, presided and welcomed some hundred-odd members and visitors. The programme was divided, after an introductory address, into two sessions of two papers each, one dealing mainly with the oxidative deterioration of fats and the other with the autoxidation of unsaturated fatty acids and esters and other topics related to drying oils and paints. Although the approach to, and aim of, this aspect of the problem are different, the chemical changes which take place have the same common basis, and for this reason the discussion on all the papers was taken together.

Prof. C. E. H. Bawn, in his introductory address, reviewed the fundamental ideas on the mechanism and chemistry of varied classes of organic molecules; for example, hydrocarbons (saturated, unsaturated, aromatic and hydro-aromatic), aldehydes and ketones, etc., which readily undergo autoxidation in the liquid or solution phase at relatively low temperatures. The radical chain theory of these processes has in recent years come to be widely accepted, and it is agreed that the initiation of the reaction requires the production of a free radical either by direct oxygen attack, photochemically or by an added agent. The reaction chain has been established to be of the following type:

$$\begin{array}{rcl} \text{Initiation} & \rightarrow & \text{free radical } R. \\ R + O_2 & \rightarrow & RO_2 \\ RO_2 + RH & \rightarrow & ROOH + R \\ R + R & \rightarrow & \multirow{3}{*}{} \\ R + RO_2 & \rightarrow & \left.\right\} \text{inert products} \\ RO_2 + RO_2 & \rightarrow & \end{array}$$

where $RH$ = hydrocarbon, aldehydes, etc.

The initially formed hydroperoxide ($ROOH$) is of varying stability, and at higher temperatures readily undergoes further decomposition. This decomposition is also a chain mechanism, and many examples conform to the following type:

$$\begin{aligned} &R\mathrm{OOH} \rightarrow R\mathrm{O} + \mathrm{OH} \text{ or } 2R\mathrm{OOH} \rightarrow R\mathrm{O}_2 + R\mathrm{O} + \mathrm{H}_2\mathrm{O} \\ &R\mathrm{O} + R'\mathrm{H} \rightarrow R\mathrm{OH} + R' \\ &R' + R\mathrm{OOH} \rightarrow R'\mathrm{OH} + R\mathrm{O}. \\ &\left.\begin{aligned} 2R' &\rightarrow \\ R' + R\mathrm{O} &\rightarrow \\ 2R\mathrm{O} &\rightarrow \end{aligned}\right\} \text{inactive products} \end{aligned}$$

where $R'\mathrm{H}$ may be parent molecule $R\mathrm{H}$, solvent or added substrate. These secondary chain reactions, together with the direct thermal decomposition of the peroxide to saturated molecules and the decomposition of the radicals $R\mathrm{O}$ and $R\mathrm{O}_2$, give rise to the variety of products—aldehydes, ketones, alcohols, acids and esters—which usually appear when the oxidation is carried to any considerable extent. It is these reactions, to which all unsaturated organic compounds in particular are susceptible, which have important practical consequences, and, as will be seen from the papers discussed, they are responsible for the development of the rancidity of fats, the gelation of drying oils and also the deterioration of rubber and other high polymers.

It is well known that the salts of the heavy metals are good catalysts for autoxidation reactions, and these reactions are of great technical importance particularly in the field of drying oils and 'controlled' oxidation to form selective intermediates, such as the oxidation of aldehydes to acid anhydrides, *cyclo*hexanol to adipic acid and *iso*propyl benzene to its hydroperoxide.

The point of view was expressed that these catalysts function essentially in the ionic form and that their activity resides in their ability to undergo electron-transfer reactions giving rise to free radicals: for example,

$$\begin{aligned} \mathrm{Co}^{++} + R\mathrm{OOH} &\rightarrow \mathrm{Co}^{+++} + R\mathrm{O} + \mathrm{OH}^- \\ \mathrm{Co}^{+++} + R\mathrm{OOH} &\rightarrow \mathrm{Co}^{++} + R\mathrm{O}_2 + \mathrm{H}^+. \end{aligned}$$

Prof. Bawn also referred to the profound effects of oxygen in polymerization mechanisms in which it may initiate and inhibit polymerization, and induce degradation, branching or cross-linking of polymer molecules according to conditions and environment.

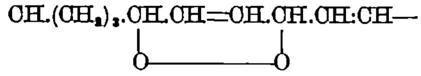
In the opening paper of the first session, Dr. C. H. Lea reviewed some recent studies of the oxidative deterioration of edible lipoids. He said that the degradation products of the primarily formed hydroperoxide, particularly $\alpha\beta$ unsaturated aldehydes and ketones, are largely responsible for the unpleasant odour and flavour of oxidized fats. The relatively rapid autoxidation of poly-unsaturated acids compared with oleic acid emphasizes the deleterious effect of even small proportions of these acids in food fats. These substances not only increase the susceptibility of the whole fat to oxidation, but also the presence of acids containing three or more double-bonds seems to be the cause of the development of the characteristic 'off' flavour, usually described as 'reverted'. The actual mechanism by which these flavours are produced is not fully understood, but the consensus of opinion appears to be that they result from the oxidation of linolenic and more highly unsaturated fatty acids to a substance of unsaturated aldehydic and ketonic structure. Traces of copper and iron favour the development of flavour in fats, and quantities as low as a few parts per million produce appreciable effects in refined oils. In this respect the presence of chelating agents which inactivate trace metals has proved to be of considerable value in improving stability. The composition of animal fat, which is influenced by such factors as diet and rate of growth, affect the susceptibility to the development of oxidative rancidity. Dr. Lea discussed evidence from recent literature that peroxidized fat may be present in the tissues of still living animals which have been subjected to ionizing radiation. This problem is being mainly studied in the United States, and it has been observed that radiation initiates oxidative reactions in many foodstuffs with the consequent development of undesirable flavours. Dr. Lea also referred to the effect of enzymatic catalysts—the lipoxidases—which accelerate the peroxidation of unsaturated fats and fatty acids. These enzymes are very specific in their action towards different types of unsaturated groupings. In the United States much work has been done on antioxidants, and these are used extensively in fats and fat-containing materials. In Britain the whole question of the addition of antioxidants to food, like that of other non-nutrient chemicals, is still under consideration.

In the second paper Dr. Banks described some observations on the autoxidation of linoleic acid. He concluded that the product is a mixture of peroxides, which cannot readily be separated; but after reduction and separation by partition between petrol ether and aqueous methanol two types of linoleic esters (hydroxy acids) are isolated. Investigations of the autoxidation of methyl linoleate in the presence of lauric and palmitic acids at 35° and 55° C. show that esterification does not occur at these temperatures, and this suggests that esters isolated are formed during reduction of the peroxides.

A review of recent work on the oxidation of mono-ethenoid fatty acids and their higher esters catalysed by metallic soaps (uranium, thorium, vanadium, etc.) was presented by Dr. Skellon. This work confirms that the primary product is a hydroperoxide which decomposes to give either epoxy, aldehydic, dehydroxy or keto-hydroxy derivatives. Oleic acid forms hydroperoxide only slowly at low temperatures, but at 85° and 120° C. this process is rapid, and the peroxide concentration passes through a well-defined maximum. Dihydroxy stearic acid, 10-hydroxy stearic acid, and small amounts of scission products have been isolated from the breakdown products of the hydroperoxide. Results were also given for the autoxidation of the *trans* isomer, ethyl, propyl and butyl esters of oleic acid, petroselenic acid, methyl recinoleate, and erucic and brassidic acids.

The drying of oil films and the manufacture of blown oils and linoleum gels are processes which depend on the formation of polymers by autoxidation. The results that have recently been obtained from extensive studies on these problems at the Paint Research Station were summarized by Dr. L. A. O'Neill. Evidence was presented in support of the view that one of the polymer-forming reactions in the autoxidation of non-conjugated drying oils results from the metallic salt-catalysed decomposition of the initially formed hydroperoxide. The main products obtained from the decomposition of the hydroperoxides of methyl linoleate and methyl linolenate are —C—C bonded dimers which retain the full unsaturation of the original esters. Some unsaturation is lost in the process, and conjugated esters are formed by double-bond shift.

The products from the autoxidation of the conjugated drying oil—methyl elaeostearate—are mainly monomeric peroxides (one of which has been isolated in the crystalline form) together with small amounts of polymeric peroxides which do not seem to be bonded by peroxide linkages. A tentative formula was proposed for the crystalline peroxide as



$$CH.(CH_2)_3.CH.CH{=}CH.CH.CH{:}CH{-}$$

Dr. O'Neill also described the results of direct studies of the autoxidation of drying oils in film form. Thus linseed oil takes up eight atoms of oxygen per molecule. Some of this oxygen is lost as volatile products, and only five atoms are retained after fourteen days. The volatiles include water, carbon dioxide, aldehydes and acid (particularly formic acid). Little change occurs in the film after a few days, and it seems necessary to postulate scission of the oxidation polymer in order to explain this high oxygen take-up.

C. E. H. BAWN

# SCIENCE AND GOVERNMENT

IN his address, "Science and Government", to the American Chemical Society at its meeting in Los Angeles on March 16, Dr. L. A. DuBridge suggested that there are three points of contact between government and science. First, the nature, form and operation of the government determine the political, economic and intellectual climate of a nation, and whether the resulting climate is favourable to science or not may be accidental. If science is to flourish, however, that climate must provide for intellectual freedom, progressive change and the recognition and encouragement of intellectual pursuits. Secondly, science and its technological applications produce changes in the way men live, requiring corresponding changes in the operations, and possibly even in the forms of government. Advances in technology are a major source of advances in human welfare. Thirdly, science and government come together most directly and intimately when science affects matters such as national defence, agriculture, industry, transport, navigation, conservation of natural resources, flood control and the weather, which are prime functions of government.

Following this, Dr. DuBridge reviewed the gradual growth in the United States of government interest in science, from the establishment of the U.S. Coast Survey in 1807 and the creation of the Smithsonian Institution in 1846, until in 1952 Federal Government expenditure on research and development in science and technology was about 1,250 million dollars, or more than 40 per cent of the country's total expenditure on research and development. More significant, however, than this increase in Federal expenditure on research, in Dr. DuBridge's opinion, is the increase in non-Federal research expenditure, from 143 million dollars in 1930 to 1,740 millions in 1952. Pointing out that it is almost impossible to distinguish rigidly between expenditure on military and non-military purposes, or even between research and development, Dr. DuBridge classified government activities according to five different management techniques commonly used: government agencies under civilian management; government agencies under military management; government-owned institutions managed privately under contract; contracts for research or development services; and contracts or grants in support of research, usually to colleges or universities.

Dr. DuBridge does not believe that the United States Government is at present getting full value from its vast expenditure on research and development. He thinks that expenditure under the fifth category—research grants—is the most fruitful and valuable. In 1952 this, however, only amounted to about 71 million dollars; and he urged that this should be substantially increased. He is concerned also that 87 per cent of these funds come from the Atomic Energy Commission and the Department of Defence, whereas, in place of the 15 million dollars requested for basic research by the National Science Foundation, the Foundation has only received 3·25 millions in 1952 and 4·75 millions this year. As regards contracts for research services, Dr. DuBridge repeated the warning frequently given by others, that universities and colleges should be chary of accepting too heavy a load of such sponsored research lest their programmes of basic research be endangered.

The opinion was expressed by Dr. DuBridge that the most successful device for development of new ideas, equipment or techniques for the military services is that of government research centres under private management, such as the Los Alamos Scientific Laboratory operated for the Atomic Energy Commission by the University of California. He believes it desirable that any new research facilities—and as many existing ones as possible—should come under the private management contracts rather than military direction. Apart from proving grounds and acceptance or inspection centres, research centres for new military weapons would be more efficient under civilian direction. It is necessary, moreover, not only to give more attention to planning weapon development expenditure but also to consider problems of grand national strategy against the background of recent scientific and technical developments. For this reason, he suggested the appointment of an outstanding scientist or engineer as scientific adviser to the Defence Department, who might also serve as chairman of the Research and Development Board. The chairman of the Atomic Energy Commission should, in his opinion, be a member of the National Security Council, and that Council should be provided with a science advisory council with a full-time chairman.

# U.S. NATIONAL SCIENCE FOUNDATION

## RESEARCH GRANTS

DURING the year ended June 30, 1952*, the National Science Foundation made ninety-six grants totalling 1,073,975 dollars for the support of basic research in the biological, medical, mathematical, physical and engineering sciences at fifty-nine institutions in the United States. Research proposals totalling 13·3 million dollars were received, of which 38 per cent were declined, withdrawn or represented reductions in budgets of approved proposals, and 54 per cent are pending. New proposals submitted in 1953 will exceed the 1952 figure, but the limited Foundation funds for research have discouraged many competent investigators from submitting proposals. Those submitted to date have been marked to an unusual extent by originality in concept, boldness in design and a desire on the part of scientists to explore important but relatively neglected fields. While there appear to be large untapped resources for research in the colleges, universities and other non-profit institutions in the United States, the Foundation has discovered many areas of great scientific interest needing additional support, and nearly 75 per cent of its financial grants went to institutions previously participating least in Federal research support. About 52 per cent of these financial grants was spent on direct assistance to graduate students and other research assistants. Of the sixty-eight grants, totalling 762,675 dollars, for biological and medical research, molecular biology claimed the most, particularly the physical chemistry of proteins and related substances found in living tissues. In this programme the work on photosynthesis is of special interest, and the Foundation, along with other agencies, is supporting photobiological research in various institutions. Much support has also been given to research on regulatory biology and to systematic biology.

---

* Second Annual Report of the National Science Foundation, Fiscal Year 1952. Pp. viii+77. (Washington, D.C.: Govt. Print. Office, 1953.) 30 cents.

In the physical sciences, 29 grants, totalling 311,300 dollars, were awarded, and the report stresses the Foundation's obligation to support integrated attacks upon borderline and inter-disciplinary problems. In the engineering sciences, the Foundation's programme places its emphasis on such fields as fluid mechanics, strength of materials, heat transfer, corrosion, and thermodynamics, which are common to several branches of engineering, and it is also encouraging research designed to fill gaps in the basic information at present available to the engineer. Special attention is being given to projects bearing on the extension of the use of strategic materials, their replacement with new, hitherto unknown, materials and the better understanding of the conversion of energy. In the terrestrial sciences, the Foundation's programme is expected to embrace eventually more or less equally studies of the atmosphere, the waters, the surface, and the interior of the earth and their interrelations, and especially microphysical processes basic to the discovery and understanding of geophysical and geochemical principles.

Of the 624 graduate fellowships in the sciences awarded in April 1952 for the academic year 1952–53, 55 were made to post-doctoral applicants. Of the remainder, 169 went to those entering their first year of graduate study, 170 to second-year graduates and the remaining 230 to advanced pre-doctoral students. Biological sciences claimed 158 fellowships, chemistry 140, physics 137, engineering 75, mathematics 62, the terrestrial sciences 36, agriculture 7, astronomy 6 and anthropology 3. While this fellowship programme immediately affects the shortage of scientific men, the Foundation recognizes that the eventual correction of that shortage requires a long-range attack on defects in the educational, social and economic structure of the United States. At present the annual output of trained men of science in the United States is ten per cent or more below demand, and the 3,600 new doctorates in the sciences each year—rather less than 10 per cent of the output of graduates—is too low to meet the expanded current needs of technology; and the situation is expected to become more critical. Meanwhile, the operation of the present National Scientific Register, for which the Foundation assumed financial responsibility after the passage of the National Science Foundation Act of 1950, was to be discontinued after December 31, 1952, when the Register should have completed the initial registration and analysis of data on scientists trained in chemistry, chemical engineering, physics, psychology, agricultural and biological sciences, geosciences, and veterinary medicine. The Foundation has established an office to assist the professional scientific societies in compiling information on scientific workers in various fields on a uniform basis.

Its survey of publications has led the Foundation to believe that no continuing Federal support of scientific periodicals is desirable at present, though in critical cases temporary emergency support may be appropriate. The development of improved methods for compiling scientific information and for its rapid handling, economical storage, and efficient distribution is being followed, and the Foundation is also giving attention to the international exchange of scientific literature, particularly the availability of foreign scientific literature in the United States. A complete survey is being made of the present pattern of distribution and processing of Russian scientific literature in the United States.

# UGANDA FOREST DEPARTMENT

## ANNUAL REPORT FOR 1951

THE annual report of the Forest Department, Uganda, for 1951[*] gives full evidence that the Government of Uganda is intent on putting into force its declared forest policy. This is noteworthy, since during the present century (a forest policy was first laid down in India during the past century) such a policy has been enunciated for several forestry departments of the British Commonwealth and remained a dead letter. The general forest policy in Uganda comprises the maintenance of an adequate forest estate for protective and productive purposes, the management of the estate to fulfil those objects, the teaching to the people of the value of forests, and the encouragement of the practice of sound forestry by local authorities and private enterprise. To carry out these objects the forest officer requires the full support of the civil administration in the district and of the headquarters Government presided over by the Governor. That the Uganda Forest Department has the full support of the civil administration is evidenced by its present position in professional matters and the great strides that have been made in recent years.

To a considerable extent this progress must have been aided by the statement on "Land Policy of the Protectorate Government in Uganda", issued by the Government in 1950. This reaffirms that rural lands are being held in trust for the use and benefit of the African population; it further goes on to state that, while the Protectorate Government retains the forest rights, the Governor may, at his discretion and regard being had to the circumstances of each case, make an *ex gratia* payment to the African local government concerned of a portion of the income derived from Crown forest rights.

That good professional administration is possible under the present régime is shown by the progress made in the enumeration of the growing stock in the forests, the preparation of working plans and the striking sylvicultural investigations being undertaken by the research staff, the plantation work being carried out for both the people and for industrial use such as tobacco, etc. The great trouble being experienced is the want of labour, and some provisions of the working plans have had to be modified for this reason. Arrangements have been made, through longer leases of forests being granted, for improvement in milling and extraction. An important part of the work is connected with the conservation and protection of forests, especially in catchment areas of rivers and streams, and on the maintenance of this work so much of the future progress and prosperity of the people will depend.

---

[*] Uganda Protectorate. Annual Report of the Forest Department for the Year ended 31st December 1951. Pp. iv+38. (Entebbe: Government Printer, 1952.) 2s.

The report was written by Mr. C. Swabey, the recently appointed conservator in Uganda, and Mr. Swabey has written a letter to me in which he takes exception to certain remarks I have made in the reviews of Uganda forest reports for 1949 and 1950 (see *Nature*, 168, 507 (1950) and 169, 1005 (1952)). In the 1949 report it was stated that local African governments were being encouraged to take over forestry work in areas where there was sufficient forest estates and that the district forest officer would act less and less in his official and trained capacity in those forests. In the report for 1950 it was stated that during the year the proposed devolution of the management of local forest areas was further developed. Past experience has shown time and again that, in the ultimate resort, the forest authority has no power to enforce regulations made by the civil authority. When the people become dissatisfied with the restrictions inevitable in good forest management, they commence to ignore them, with the result that friction arises which may easily go further. To avoid this in the past, the methods of forest management have had to be modified, at the instance of the civil authority. Improvements in the forest area and its usefulness may then disappear in a very short time. This will be the final test for a Department which, as the present report demonstrates, is making magnificent progress with the full support of the Governor and civil administration behind it.

E. P. Stebbing

# STRYCHNINE AS A DEPRESSANT OF PRIMARY INHIBITION

By K. BRADLEY and Prof. J. C. ECCLES, F.R.S.

Departments of Physiology, University of Otago, Dunedin, New Zealand, and the Australian National University, Canberra

THERE have been many investigations on the convulsive action of strychnine[1-7]; but it has hitherto not been possible to determine the essential nature of the action. For example, it would still be possible to hold that strychnine transforms inhibitory synaptic action into excitatory action, or alternatively that it merely intensifies excitatory synaptic action. No decisive experimental test has been possible because the testing reflexes have always been evoked by afferent volleys composed of admixtures of excitatory and inhibitory impulses. Even a pure group I afferent volley from a muscle nerve will exert, by virtue of its group I*a* and I*b* components respectively, excitatory and inhibitory actions on homonymous motoneurones and inhibitory and excitatory actions on antagonist motoneurones[8-10]. Perhaps the only significant evidence is that in subconvulsive doses strychnine has little or no effect on the monosynaptic reflex discharge, while there is a great increase in polysynaptic discharges[1,2,5,6]. Since the monosynaptic discharge evoked by group I*a* impulses would occur before the complicating disynaptic inhibitory effect of the group I*b* impulses[9], this evidence indicates that strychnine does not appreciably intensify the monosynaptic excitatory action of group I*a* impulses.

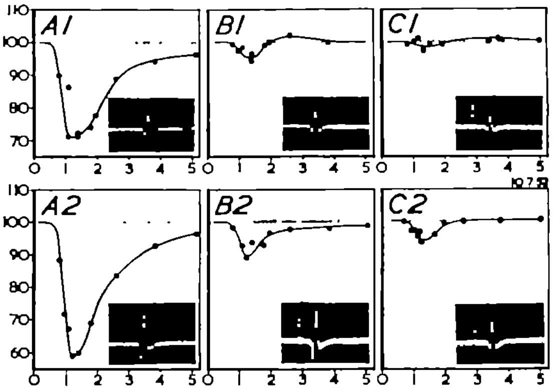


Fig. 1. Height of test reflex spike resulting from a single maximal afferent volley on biceps-semitendinosus nerve. Recorded from $S_1$ ventral root, and preceded at various intervals by an inhibitory volley in quadriceps nerve. Ordinates, heights of test reflexes as percentages of control height. Each point is mean of twenty observations as determined by method of superimposed tracings. Abscissae, interval in milliseconds between inhibitory and test afferent volleys as recorded by an electrode in contact with the $L_7$ dorsal root close to its entry into the spinal cord

The present communication is principally concerned with the effect produced by strychnine on the direct inhibitory action which group I*a* impulses in the quadriceps nerve exert on the antagonist biceps-semitendinosus motoneurones. The initial requirement of this investigation was to distinguish between group I*a* and I*b* impulses in the afferent volley. In some, but not all, low spinal cat preparations under nembutal anaesthesia, a group I afferent volley set up in the quadriceps or biceps-semitendinosus nerves gives a double spike potential when it is recorded triphasically by a surface lead from a dorsal root as it is about to enter the spinal cord (cf. Fig. 3 and the lowest two inset records of Fig. 2). The second spike has a higher threshold than the first, and often it is possible to have the first spike more than half maximal with no detectable contamination by the second, as is shown in Fig. 3, in which the first stimulus was varied in strength from just above group I*a* threshold to about three times this strength, while the second stimulus was about three times

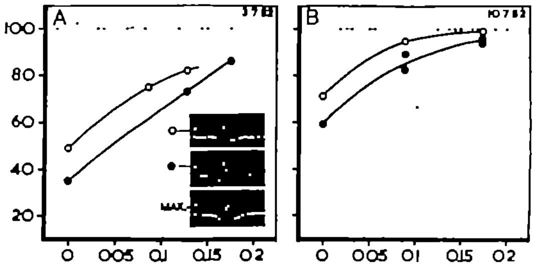

Fig. 2. Plots of test reflexes taken at the interval after the inhibitory afferent volley giving maximal effect (cf. Fig. 1), and expressed as percentages of control test reflexes (ordinates) against dosage of strychnine (mgm./kgm. body-weight: abscissae) in two experiments. In each experiment two sizes of inhibitory volley have been used. In graph *A*, the smaller inhibitory volley (open circles) contained little, and the larger (filled circles) considerable group I*b* contribution (see in inset dorsal root spikes for corresponding symbols). In graph *B* the two inhibitory volleys are those used in Fig. 1

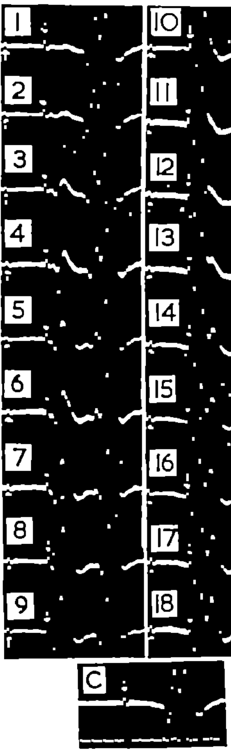

Fig. 3. Triphasic records of two group I afferent volleys from quadriceps nerve and recorded by a surface electrode on $L_6$ dorsal root close to its entry into the cord. Each record is formed by superposition of twenty faint traces in order to minimize random noise *C* gives control response to second stimulus alone with two spikes (I*a* and I*b*) 0·17 m sec. apart

threshold and 0·68 m.sec. later, so that it failed to excite any fibres that were excited and made refractory by the first. In records 7 and 8 there is virtually no group I*a* spike in the second response, that is, the first stimulus excited almost all I*a* fibres and yet virtually no I*b* fibres. Appreciable I*b* excitation only occurs from record 9 onwards. In this way it has been shown that the afferent impulses represented by the earlier spike cause monosynaptic excitation of homonymous and inhibition of antagonist motoneurones, whereas impulses of the second spike have no detectable monosynaptic action, that is, the first and second spikes are identifiable as group I*a* and I*b* respectively.

Fig. 1 (*A*1) shows the time course of the inhibitory effect of a group of I*a* afferent volley with no significant contamination by group I*b*. A subconvulsive dose of strychnine (0·09 mgm./kgm.) diminishes and shortens the inhibition (*B*1) and a further dose (0·08 mgm./kgm.) virtually abolishes the inhibition (*C*1). In *A*2, *B*2, *C*2 the quadriceps afferent volley is larger but still contains few, if any, fibres of group I*b*. The control inhibitory curve resembles that of *A*1, but the inhibition is larger, corresponding to the larger size of the group I*a* volley. There is likewise a corresponding diminution of the inhibition by the two doses of strychnine. Note that this diminution is much larger than the relatively small decrease in the dorsal root volley.

The effect of strychnine in diminishing the direct inhibitory action of group I*a* afferent impulses has been observed in all our experiments (eleven in all). Typical dose-response curves are shown in Fig. 2. Strychnine has also been observed to depress the polysynaptic inhibitory effect of cutaneous afferent volleys. Thus strychnine would seem to have a specific depressant action on synaptic inhibition, for this action is observed with doses which have no significant action on synaptic excitation as tested by the monosynaptic reflex.

Two alternative explanations of this specific action may be suggested: that strychnine acts competitively to reduce the bonding of an inhibitory transmitter substance with the subsynaptic membrane, much as curare is believed to depress the action of acetylcholine at neuro-muscular junctions and ganglionic synapses; or that strychnine interferes with the inhibitory action further downstream, for example, by depressing the hyperpolarizing action of the postulated inhibitory transmitter substance[11,12].

Finally, this specific effect of strychnine gives rise to the question: How far is it possible to explain its convulsive activity solely by its depressant action on inhibition? At least it is the simplest initial postulate that depression of the inhibitory synaptic action on interneurones causes the great apparent increase in polysynaptic excitatory action[1,6] which is so characteristic a feature of the strychninized nervous system. # STRUCTURE OF ASPARAGINE

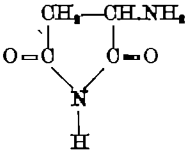
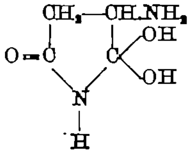
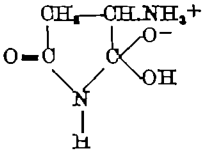
STEWARD AND THOMPSON have recently discussed the properties of glutamine and asparagine and proposed a new cyclic structure for asparagine[1].



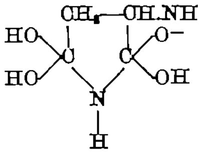
(1)



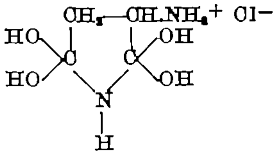
(2)



(3)



(4)



(5)

In the accompanying formulæ, (1) represents the (hypothetical) parent structure used by Steward and Thompson, amino-succinimide. (2) and (3) represent the uncharged and zwitterionic forms of anhydrous asparagine respectively, whereas (4) is their formulation of the monohydrate. The authors apparently consider asparagine in solution as a tautomeric system in which the cyclic form is in equilibrium with the conventional straight chain, but with the former very much preponderating.

It seems to us that there are many difficulties associated with this view. Since Steward and Thompson regard the straight-chain formulation as correct for glutamine, their arguments based on different chemical properties of asparagine and glutamine lose force in view of the postulated tautomerism of asparagine. An equilibrium of this type could explain additional properties of asparagine and slower rates of reaction through the straight-chain form compared with non-tautomeric amides. It could not, however, explain the complete failure of nitrous acid to react with the asparagine amide group, since other reactions of the straight-chain form (for example, with acid, alkali or ninhydrin) take place at a measurable rate. Furthermore, many of the arguments advanced by Steward and Thompson in favour of a cyclic structure for asparagine apply with equal force to *iso*-asparagine, which also exists in the form of a hydrate. However, the analogous structure for *iso*-asparagine hydrochloride would be formula (5), which also represents asparagine hydrochloride. The two substances should therefore be interconvertible in solution, whereas they are, in fact, quite distinct chemically.

Our view is that the straight-chain formulation, possibly modified by hydrogen bonding, adequately represents the structure of asparagine, and that most of the differences in behaviour between asparagine and glutamine represent anomalies in the behaviour of glutamine rather than asparagine. Thus it is definitely glutamine which is anomalous in its behaviour towards nitrous acid, since its amide group reacts very readily. Other amide groups do not normally react with nitrous acid under the conditions of the van Slyke estimation, but require prolonged reaction in the presence of mineral acid[2]. Moreover, in proteins where, as Steward and Thompson admit, only the straight-chain formulation is possible for the combined asparagine, it is known that amide groups react with nitrous acid only very slowly if at all, even in the presence of mineral acid[3]. In its ease of hydrolysis to liberate ammonia, glutamine has been described as a "unique amide"[4], whereas investigations we have just completed show that the rate of hydrolysis of asparagine by acids is similar to that of acetamide under comparable conditions and gives normal values for the energy and entropy of activation. It should also be noted that substitution of the amino group of glutamine, as, for example, in leucylglutamine, slows down the rate of hydrolysis of the amide group to a rate of the same order as that of asparagine[5] and also causes the amide group to become unreactive towards nitrous acid[6]. On the other hand, it is of interest that N-methylation of the amide group of glutamine does not affect the reaction with nitrous acid[7], and in glutathione, a γ-glutamyl peptide, this reagent also reacts with some of the peptide nitrogen[8].

More conclusive evidence against the cyclic structure of asparagine has emerged from our kinetic studies on the rate of hydrolysis of the amide group of asparagine peptides. Inspection of Steward and Thompson's cyclic structure shows that it cannot be maintained for peptides of the type asparaginylglycine, whereas glycyl- or leucyl-asparagine could still possess a cyclic structure. If the hypothesis of ring structure is correct, therefore, one could expect similarities of behaviour between the amide groups of asparagine and peptides of the glycylasparagine type, but contrasting behaviour from peptides of the asparaginylglycine type. Kinetic data on the acid hydrolysis of the amide group show the converse of this relationship. The hydrolysis of the amide group of L-asparagine and L-asparaginylglycine by acid are both second-order reactions, being first order in amide and hydrogen ion. Moreover, the rates of both reactions are similar, and derived thermodynamic data are reasonably comparable for both compounds. Glycyl- and L-leucyl-L-asparagine, however, both show behaviour contrasting sharply with that of asparagine on acid hydrolysis. For these peptides the reaction is first order only in the molecular species of the type glycylasparagine hydrochloride, and the rate of hydrolysis is independent of hydrogen ion concentration at *p*H values where this ionic form preponderates. Under comparable conditions the amide groups of these peptides hydrolyse much more rapidly than those of asparagine and asparaginylglycine, the greater rate being due to a more positive entropy of activation.

Full data on these kinetic experiments will be published shortly.

January 6. Since submitting this communication, we have read the letter by Katz *et al.*[9] on the three-dimensional X-ray analysis of the structure of glycyl-L-asparagine crystals. This provides additional direct evidence against the cyclic structure proposed for asparagine by Steward and Thompson.

---

THROUGH the courtesy of Drs. Leach and Lindley, we have seen their communication on the structure of asparagine, prior to its publication. This and numerous other comments that we have received testify to the interest which our article[1] aroused. In that sense, part of our purpose was achieved, since we wished to direct attention to the problem. Other recent and relevant communications are those of Katz, Pasternak and Corey[2] and of Cochran and Penfold[3], and a paper by Davies and Evans sent to us prior to its submission to the Chemical Society in London.

These communications may be summarized as follows.

(1) In the form of its peptides and even in certain cases where asparagine occupies a terminal position, the evidence of crystal structure is consistent with the combined asparagine existing in the conventional open-chain form[2].

(2) Cochran and Penfold[3] have published their evidence, referred to by us as communicated privately

from Dr. Pepinski, which shows crystalline glutamine has the open-chain form.

(3) Davies and Evans[4] have re-examined the infra-red absorption spectra of asparagine and glutamine and, as a result of this, they prefer the alternative structure for asparagine which was suggested to us by Dr. M. L. Huggins.

(4) Leach and Lindley refer again to the general problem, and from evidence derived from the rates of hydrolysis of peptides they now question whether there is any major structural difference between asparaginyl-glycine and glycyl-asparagine. Since the latter could contain asparagine in the ring form, this is interpreted by Leach and Lindley to mean that the ring form of asparagine does not exist.

(5) Leach and Lindley also state that their evidence indicates that asparagine is decomposed by acid at a rate more comparable to that of acetamide than to that of glutamine.

It should be recognized that we were concerned to explain certain stated differences in both chemical and physiological properties of *free* asparagine and glutamine in solution. It is of interest, as indeed we suggested, if these differences extend to situations in which the asparagine and glutamine are present in the form of their compounds. On the other hand, the fact that the compounds of glutamine and asparagine, or even their crystals, do not exist in the stipulated form does not necessarily disprove the postulated structure for free asparagine. We are still left with the problem of explaining the marked differences between these two compounds as they occur in the *free* state and in solution.

Leach and Lindley refer to the fact that *iso*-asparagine exists and that this compound also might occur in a cyclic form. Of this we were well aware; but since we had no data on which to base comparison of the relevant properties of *iso*-asparagine and asparagine, it did not seem helpful to refer to this interesting compound, which does not apparently occur in Nature. So far as we can tell, Leach and Lindley have not compared *iso*-asparagine with asparagine and/or glutamine. Until this is done, any speculations on *iso*-asparagine are scarcely relevant. It is true that in the ring form *iso*-asparagine and asparagine would not be distinguishable; but the position of the amino group may greatly affect the relative stability of the respective open-chain forms compared with the supposed ring. Since *iso*-asparagine seems to react blue with ninhydrin under the conditions in which asparagine reacts brown, it would seem to resemble glutamine more than asparagine in this respect.

With respect to the contrasted behaviour of asparagine and glutamine to nitrous acid, the definitive thing is that in the one compound (glutamine) both nitrogen groups react, whereas in the other (asparagine) only the amino group reacts. Leach and Lindley have in no way explained this difference. It still seems reasonable to us that, if the ring form exists, the equilibrium might be far in this direction and, this being so, and in the absence of special evidence to the contrary, this could be consistent with the virtual failure of nitrous acid to react with the amide group.

Leach and Lindley re-discuss the decomposition of the amides, asparagine and glutamine. They treat this as though hydrolysis alone were involved. It is, however, evident that on one hand (asparagine), hydrolysis and, on the other (glutamine), cyclization by loss of ammonia may be involved. This complicates comparisons with other amides. When the glutamine is substituted in the amide group, this precludes cyclization by loss of ammonia, and therefore the decomposition of such compounds by acid should resemble that of asparagine more than that of free glutamine. While we again recognize that this problem is a difficult one to resolve conclusively, we also believe that the arguments of Leach and Lindley have not yet led to finality.

The evidence of infra-red absorption spectra, as it was available to us through Dr. Gore, seemed to indicate a difference of structure between crystalline glutamine and asparagine. It is this evidence which Davies and Evans[4] now call in question from their re-examination; but they make significant reference to the fact that the spectrum of crystalline asparagine is somewhat variable from sample to sample in certain of the critical regions. A re-examination of an anhydrous specimen of asparagine, as carried out for us by Dr. Gore, still indicates a difference in absorption between asparagine and glutamine in the general region of 1,420 cm.$^{-1}$. We now recognize that the absorption of asparagine at 1,530 cm.$^{-1}$, which is still evident, should not be described as 'strong' (ref. 1), though it is not present in glutamine and we believe is not due to water as Davies and Evans suggest.

However, the cumulative evidence to which we referred[1], together with the new evidence which we were able to derive by the use of the ninhydrin reagent as applied to asparagine containing carbon-14, still seems to us to be in favour of a ring configuration for free asparagine as it exists in solution.

Although all these papers are of interest, they are scarcely conclusive. As we said earlier, the determination of the structure of asparagine by X-ray methods could be unequivocal for crystalline asparagine, whereas a synthesis of amino succinimide would also be conclusive according as it proved to be, when hydrated, identical or different from asparagine.

*Note added in proof.* Evidence bearing on the properties of asparagine and glutamine also comes through the work of Meister[5] on their α-keto acid analogues. Asparagine yields two separable keto compounds (*A* and *B*). One of these (*B*) readily gives a 2-4 dinitrophenyl hydrazone, readily decarboxylates and has an ultra-violet spectrum similar to that of a β-keto acid (cf. oxaloacetic). The other (*A*) does not give a phenylhydrazone, lacks the ultra-violet absorption and decarboxylates with more difficulty: this compound may be either cyclic or a polymer. Glutamine may also yield two keto analogues, though only one (*A*) has been isolated (as its barium salt) free from the other (*B*). Compound *A* gives a phenyl hydrazone; the amide group is easily hydrolysed giving α-keto glutaric acid. Compound *B*, which is less stable, has not yet been isolated. The further outcome of this work will be awaited with considerable interest.

## Incorporation of 8-Azaguanine into Nucleic Acid of Tobacco Mosaic Virus

THE guanine analogue, 5 amino-7-hydroxy-1-v-triazolo(*d*) pyrimidine (guanazolo; 8-azaguanine), delays or inhibits the development of infection in the case of several plant virus diseases[1]. The activity of the compound is reversed by adenine, guanine and probably hypoxanthine, but not by several other naturally occurring purines. On current views of the action of antimetabolites, these facts would suggest that 8-azaguanine acts by blocking an enzyme system involved in the utilization of guanine and perhaps adenine by the virus. There is, however, the possibility that 8-azaguanine is sufficiently like guanine to be incorporated into the virus nucleic acid, replacing some of the guanine, but different enough to make a virus particle containing it incapable of further multiplication. With tobacco mosaic virus in inoculated tobacco leaves, 8-azaguanine causes a delay in the production of virus (measured by infectivity, by particle counts using electron microscopy, or by yield of extractable virus[2]). The results described here show that 8-azaguanine is incorporated into the nucleic acid of tobacco mosaic virus.

Tobacco plants, inoculated with a highly infective preparation of a 'type' strain of tobacco mosaic virus, were sprayed twice weekly, on all leaves, with 0·01 *M* 8-azaguanine in 0·1 per cent sodium bicarbonate, commencing the day after inoculation. Batches of treated and untreated plants were harvested at various times between three and thirty days after inoculation. Preparations of tobacco mosaic virus were obtained by the usual ammonium sulphate precipitation procedure. The method for isolation of virus nucleic acid and the analytical procedures used were those of Markham and Smith[3]. The method of printing chromatograms by the fluorescence of the spots[4] has proved particularly useful, since 8-azaguanine fluoresces strongly under both acid and alkaline conditions, while guanine compounds fluoresce strongly under acid conditions only. In addition, with 8-azaguanine the fluorescence method is about ten times as sensitive as printing by absorption. About 0·3 μgm. of 8-azaguanine can be detected on No. 1 Whatman paper printing on Grade 1 bromide paper.

On analysis, the virus nucleic acid from treated plants was found to contain less guanine (by approximately 3·5 per cent) than that from untreated plants. This deficiency was accounted for entirely (within the limits of experimental error) by an increase in adenine (Table 1). In the *iso*propanol–hydrochloric acid solvent used, 8-azaguanine would run with and be estimated as adenine.

Table 1. MOLAR RATIOS OF BASES IN NUCLEIC ACID OF TOBACCO MOSAIC VIRUS FROM CONTROL AND 8-AZAGUANINE-TREATED PLANTS

| Base | Molar ratios (means of 7 determinations) | | Difference control-treated | Difference required for significance at 0·01 *P* |
|---|---|---|---|---|
| | Control | 8-Azaguanine treated | | |
| Guanine | 0·979 | 0·943 | − 0·036 | 0·024 |
| Adenine | 1·103 | 1·134 | + 0·031 | 0·031 |
| Cytosine | 0·817 | 0·815 | − 0·002 | 0·021 |
| Uracil | 1·101 | 1·110 | + 0·009 | 0·058 |

When acid-hydrolysed nucleic acid (*N* hydrochloric acid, 1 hr., 100° C.) was run on two-dimensional chromatograms (first solvent: *iso*propanol–hydrochloric acid; second solvent: *iso*propanol–ammonia) an additional small fluorescent spot was present behind adenine in the second solvent system in the hydrolysate from treated virus, in the position expected for 8-azaguanine. The fluorescent material isolated by this procedure had an electrophoretic mobility on filter paper in borate buffer at *p*H 9 corresponding to that of 8-azaguanine.

In attempting to isolate 8-azaguanylic acid from alkaline hydrolysates of nucleic acid, advantage was taken of the fact (determined by paper electrophoresis) that the *pK*'s of the hydroxyl and amino groups in the triazolopyrimidines are lower than those for the corresponding purines. In the case of 8-azaguanine, the *pK* of the hydroxyl group is about 3 *p*H units lower than that of guanine. When nucleic acid from virus from 8-azaguanine-treated plants was hydrolysed with 1 *N* sodium hydroxide (at room temperature for 24 hr.) and subjected to electrophoresis on filter paper in borate buffer at *p*H 9, a fluorescent band was found, running in a positive direction slightly ahead of uridylic acid, the fastest-moving of the naturally occurring nucleotides at this *p*H. This band, which was absent in control preparations, moved about 1·4 times as fast as 8-azaguanine—approximately the mobility to be expected for 8-azaguanylic acid. This procedure was used to isolate the fluorescent compound free from other absorbing material except traces of uridylic acid. This was removed by chromatography in *iso*propanol–ammonia. Table 2 gives the approximate $R_F$ values of the fluorescent material and other compounds in two solvent systems.

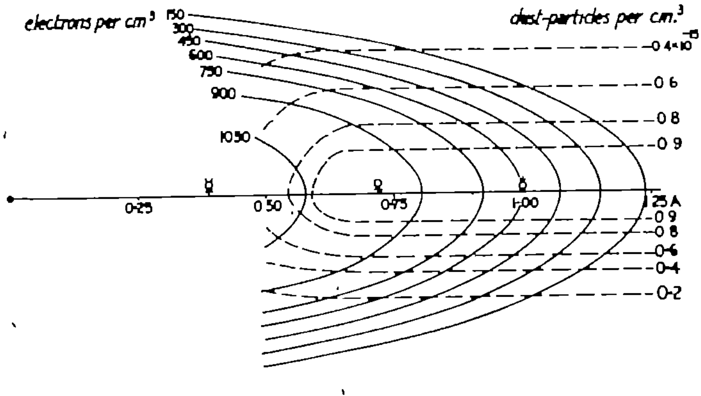
Table 2

| Compound | Approximate $R_F$ in . | | |
|---|---|---|---|
| | *Iso*propanol–ammonia | Ammonium sulphate–water | |
| Guanine | 0·33 | | 0·16 |
| Guanylic acid | 0·08 | *a* | 0·33 |
| | | *b* | 0·42 |
| 8-Azaguanine | 0·27 | | 0·17 |
| 8-Azaguanylic acid | 0·05 | *a* | 0·33 |
| | | *b* | 0·40 |

In the ammonium sulphate solvent, the fluorescent material divided into two spots running in the expected positions for 8-azaguanylic acids *a* and *b*. This is strong evidence for the production of 8-azaguanylic acid from polynucleotides through the cyclic phosphate[5].

The fluorescent compound contains phosphorus and had a base / phosphorus ratio of 1·4 / 1·0 (on one determination on only 0·5 μgm. of phosphorus). From the above we conclude that the fluorescent compound in alkaline hydrolysates is 8-azaguanylic acid, and that therefore 8-azaguanine is incorporated into the nucleic acid of tobacco mosaic virus. In two previous claims for the incorporation of 8-azaguanine into nucleic acids[6], since the material was isolated only as 8-azaguanine, the possibility that it was present as a contamination in the nucleic acid preparations was not eliminated.

In view of the large errors in infectivity measurements, it may be very difficult to prove whether, in fact, 8-azaguanine incorporated into the nucleic acid renders a virus particle 'sterile'.



Lines of equal density for electrons and dust particles in the planetary system in a plane perpendicular to the ecliptic. Position of sun and inner planets marked by their symbols

The incorporation of 8-azaguanine suggests more directly than did reversal experiments that at least some plant viruses can utilize free guanine for synthesis.

In young pea embryos, most of the 8-azaguanine absorbed is fairly rapidly deaminated to give 8-azaxanthine, a compound which is inactive against all plant viruses that have been tested. If this deamination occurs in leaves of more mature plants, then most of the 8-azaguanine is rendered inactive. It would be in accordance with much recent evidence[4] suggesting the primary role of nucleic acids in virus infectivity to assume that 8-azaguanine has its effect through being incorporated into the nucleic acid and thus rendering the particle 'sterile'. If these assumptions be correct, it may prove profitable to search for a compound that will not be subject to deamination and that will lead to an increased incorporation of 8-azaguanine into the virus nucleic acid. From work on the biosynthesis of the natural purines into ribonucleic acids in other systems[7], two compounds that may have these properties in some degree are 8-azaguanylic acid itself (particularly the *b*-isomer) and the triazole equivalent of 4-amino-5-imidazole carboxamide.

I wish to thank Mr. P. R. Fry for some of the tobacco mosaic virus preparations, and Dr. Roy Markham for much useful discussion. This work was carried out while I was on leave from the Plant Diseases Division, Auckland, New Zealand.

## Photoelectric Observations of the Zodiacal Light

It has been generally accepted that the zodiacal light comes from the scattering of solar light by dust-particles in the planetary system, which are concentrated towards the earth's orbital plane. On the other hand, it is known that the sun emits continuously a variable number of charged particles, principally protons and electrons. The possibility that the free electrons give some part of the luminosity of the zodiacal light has been discussed by F. L. Whipple and J. L. Gossner[1], who derived maximum values of the possible electron densities in the space between sun and earth. For the following discussion of the density of electrons and dust particles in the planetary system we use the results of photoelectric registrations of brightness and polarization in the zodiacal light with a 1 *P* 21-multiplier. These were obtained during February/March and October 1952 and in the recent winter at the Hochalpine Forschungsstation Jungfraujoch (altitude 3,600 m.). Details of the apparatus and the observing and reduction methods are given in a paper by A. Behr and H. Siedentopf[2].

The spatial densities of electrons and dust particles were derived from the observed values of brightness and polarization on the assumption that the polarized part arises only from the scattering by free electrons, whereas the dust-particles give no appreciable polarization. This supposition can be justified by the Mie theory of scattering by small particles. Since for dust particles with radii less than $10^{-4}$ cm. the radiation pressure of the sun is greater than the gravitational attraction, the main effect comes from particles with radii about $10^{-5}$ cm. (the number of particles per unit volume $n(r)$ decreases with radius $r$ nearly as $n(r) \sim r^{-3.5}$). For a mixture of particles with different radii it can be shown[3] that, for the angles of scattering encountered, there results no appreciable amount of polarization. Only if the particles are of oblong shape and if their axes are aligned, for example, by an interplanetary magnetic field, might a certain amount of polarization by the particles be possible. If this should be really the case, the number of electrons given in the accompanying diagram must be considered as an upper limit.

The diagram shows the mean distribution of electrons and dust particles as derived by solving numerically the integral equations connecting the brightness and polarization at the sphere with the density of electrons and particles in space. Whereas the observed polarization, and therefore the electron distribution, is symmetrical about the ecliptic, there is a distinct asymmetry in the distribution of brightness, also found by other observers. This asymmetry can be represented by a steeper decrease of particle numbers on the southern side of the ecliptic than on the northern side. We are not yet sure of the amount of this asymmetry, since the elimination of the ground brightness on the northern side of the evening zodiacal light is difficult because of the neighbourhood of the Milky Way and the increase of the air-glow towards the northern horizon. The numbers of dust particles given for the southern side of the ecliptic are therefore more reliable.

The resulting electron-density of about 600 per cm.$^{-3}$ near the earth's orbit gives a gas-density of about $10^{-21}$ gm.cm.$^{-3}$, since for electrostatic equilibrium one proton or other positive ion is necessary for each electron. The density of the dust—$10^{-15}$ particles cm.$^{-3}$—comes out to about $10^{-23}$ gm.cm.$^{-3}$ near the earth, or only a hundredth of the density of the gas. The decrease of density of dust towards the sun as shown in the diagram may be the result of evaporation of dust particles near the sun, as is similarly found in the nuclei of comets.

The brightness of the light-bridge connecting the morning and the evening zodiacal light is correctly represented by the above dust density (the contribution of the electrons to the light-bridge is small since their number decreases rapidly outwards). The luminosity near the counterpoint of the sun, the so-called counterglow (*Gegenschein*) with a diameter of about 20°, is 30 per cent higher than in the light-bridge. If the counterglow is explained as the result of a cloud of dust-particles near the outer libration-point in the system sun–earth[4], this cloud is situated at a distance of 0·01 astronomical units from the earth and has a density about thirty times higher than the mean density of dust near the earth's orbit.

## Action of Cortisone on the Polymerization of Actin

In adrenalectomized animals maintained on an adequate diet, the work capacity of skeletal muscle, as shown by the response to prolonged repetitive stimulation, is greatly diminished[1]. This effect is apparently not due to a direct failure of energy supply as could be expected from hypoglycaemia, but to an alteration in the metabolic or contractile system of the cell.

It has been shown by Horvath *et al.*[2] that the cardiac glycosides enhance the polymerization of actin prepared from cardiac muscle but do not affect actin from skeletal muscle. These observations have been confirmed in this laboratory, and the possibility that cortisone might act in a similar manner on skeletal muscle actin alone has been investigated.

Actin was prepared from skeletal muscle of the dog by the method of Straub *et al.*[3]. Solutions obtained by the extraction of 1 gm. of dry powdered muscle residue with 20 ml. of carbon dioxide-free distilled water had an actin content of 5–6 mgm./ml. Polymerization was followed by viscometry measurements at 10° C. using the Ostwald viscometer.

Our results show that cortisone in a concentration of 25 μgm./ml. added as a solution in propylene glycol increased the rate of polymerization twofold compared with a control preparation containing the solvent alone and of identical ionic constitution. This effect is apparent throughout the range of concentration of cortisone 0·25–50 μgm./ml. The polymerization was carried out at the physiological ratio of potassium to calcium (potassium, 0·054 *M*; calcium, 0·001 *M*) with a trace of magnesium (0·0005 *M*) and in the presence of veronal-acetate buffer of *p*H 7·4. All salts were present as chlorides.

Under identical conditions, actin prepared from the cardiac muscle of the dog showed no alteration in polymerization-rate when cortisone was present in a concentration of 25 μgm./ml.

The globular to fibrous transformation of actin effected by ions *in vitro* is an extreme case of small changes occurring in the actin particles in the intact cell and gives a good indication of these reactions. It would seem that steroid substances have a role in the regulation of contractile force through an influence on actin particles.

## Serum as a Source of Growth-factors for *Trichomonas fœtus*

Cailleau[1] concluded that cholesterol, ascorbic acid and a third unidentified factor were essential for growth of *Trichomonas fœtus*. Ascorbic acid, however, may only have been required because of its reducing properties[2]. The object of the present study was to investigate the nature of the factors in serum required by *T. fœtus* when grown in bacteria-free culture.

Stock cultures of the organisms were grown in 2 per cent glucose-broth over an inspissated serum slope, the medium being covered with a layer of liquid paraffin. Experimental cultures were grown in broth containing 2 per cent glucose and 7 per cent liquid horse serum. The inoculum gave an initial count of 200,000 organisms per ml. Without serum no significant multiplication took place; but when present in the medium a population of up to ten millions per ml. was obtained.

Preliminary investigations led to the preparation of a water-soluble extract of inspissated serum which would support growth when added to glucose broth. It was prepared by steaming together for 45 min. equal volumes of inspissated serum and distilled water. The final *p*H was 8. After steaming, the extract was cleared in a Seitz filter and then freeze-dried. The extract could be dialysed without loss of activity. When added to 2 per cent glucose-broth to give a concentration of approximately 0·15 per cent in terms of its protein content, optimum growth was obtained which could be serially subcultured. The extract contained a considerable amount of protein which could be precipitated by trichloracetic acid or by heating at *p*H 5.

The following analyses on a sample of the freeze-dried extract were kindly carried out by Dr. Winifred Watkins, who reported the material to contain total nitrogen, 10·5 per cent; total phosphorus, 0·6 per cent; inorganic phosphorus, 0·005 per cent; reduction and hexosamine (after hydrolysis for 8 hr. at 100° with 0·5 *N* hydrochloric acid), 4·6 per cent and 2·4 per cent respectively. The substance gave a positive biuret and Liebermann–Burchard (cholesterol) reaction.

The method of preparation suggested that the extract might contain seromucoid, and the results of the analysis support this possibility. The total carbohydrate content is 4·6 per cent compared with a content of 10·7 per cent in seromucoid; but the ratio of hexose to hexosamine is approximately the same as that recorded for seromucoid³. The low carbohydrate value may be due to the amount of precipitable protein present.

The growth-promoting activity of the serum extract was not due solely to its cholesterol content, since by itself cholesterol would not support growth.

The essential components of serum for *T. foetus* have thus been shown to be water-soluble, non-dialysable and stable to heating at *p*H 8. It is considered possible that one of the factors required may be seromucoid. The work is being continued, and it is hoped to elucidate further the nature of the growth-factors required by this organism.

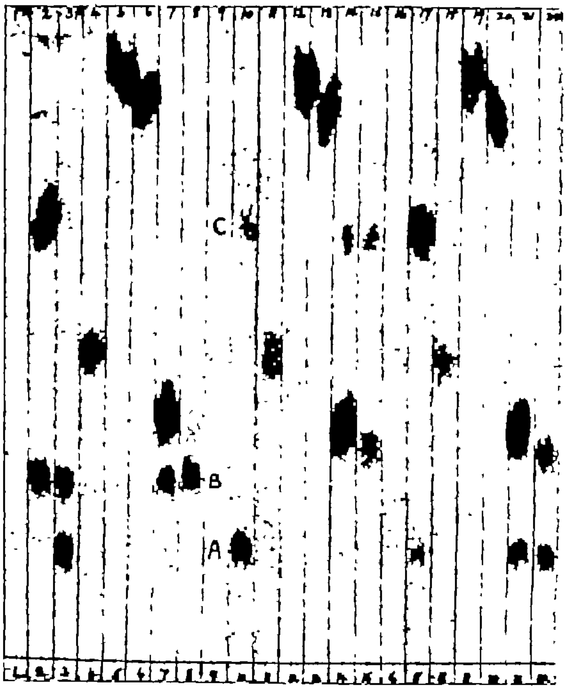
## A New Transamination Reaction

THE isolation of γ-methylene-glutamine and γ-methylene-glutamic acid from groundnut plants has been described¹. More recent studies, in which an attempt has been made to obtain information regarding the metabolism of the compounds, have indicated that transamination processes may be largely responsible for the breakdown of the γ-methylene-glutamic acid in groundnut plants.

The first experiments were of a qualitative nature only. Seeds germinated for four days at 25° in the dark were ground with half their fresh weight of *M*/5, *p*H 7·4, phosphate buffer solution and a little acid-washed sand until a smooth paste was obtained. The paste was squeezed through fine muslin and the filtrate centrifuged for 5 min. at 3,000 r.p.m. to remove finely divided debris. The supernatant was then enclosed in a collodion bag and dialysed against a stream of *M*/5, *p*H 7·4, phosphate buffer for 24 hr. at 3° in order to remove most of the free amino-acids found in the original extract. After dialysis the extract was used directly in the transamination experiments to be described.

The efficiency with which the α-amino-group of γ-methylene-glutamic acid was transaminated to three α-keto-acids (α-keto-glutaric, pyruvic and oxalacetic acids) was compared with that of certain other *l*-amino-acids previously found to participate in transamination systems in plant materials². The reaction mixtures consisted of one volume of *M*/35 α-keto-acid solution (titrated to *p*H 7·4), one volume of *M*/35 *l*-amino-acid solution and two volumes of the extract. The amino-acids used were *l*-aspartic acid, *dl*-alanine, *l*-valine, *dl*-leucine, glycine and γ-methylene-glutamic acid (concluded to be the *l*-form from unpublished experiments). Synthetic γ-methyl-glutamic acid (presumably a *dl*-form) was also used. Transamination was allowed to proceed for 4 hr. at 38°, and then the enzymes were inactivated by the addition of absolute alcohol to a final concentration of 70 per cent followed by warming. After the precipitated proteins had settled, aliquots of the supernatants from each reaction mixture were applied as spots to a chromatogram later developed in the usual manner for 24 hr. in phenol – ammonia. The relative amount of the products of the transaminations (glutamic acid, alanine and aspartic acid) can be estimated approximately from the sizes and intensities of the ninhydrin-developed spots on the chromatogram. The photograph of the chromatogram produced here shows that when α-keto-glutarate was used, the maximum and approximately equal amounts of glutamic acid were produced from γ-methylene-glutamic and γ-methyl-glutamic acids, alanine and aspartic acid. When pyruvate or oxalacetate was used, the maximum amounts of alanine or aspartic acid appeared to be produced when γ-methylene-glutamic and γ-methyl-glutamic acids were employed. The reactions between α-keto-glutarate and the three amino-acids, alanine, aspartic acid and natural γ-methylene-glutamic acid, when studied at intervals of 0·5 *p*H units between 5·0 and 8·5, all had *p*H optima of about 7.



Chromatogram prepared from 100 µl. amount of the following reaction mixtures. Nos. 1–8 contained 2 parts of extract, 1 part of *M*/35 α-keto-glutarate and 1 part of *M*/35 *l*-amino-acid as (1) water, (2) alanine, (3) aspartic acid, (4) glycine, (5) leucine, (6) valine, (7) γ-methyl-glutamic acid, (8) γ-methylene-glutamic acid. Nos. 9–15 contained 2 parts of extract, 1 part of *M*/35 pyruvate and 1 part of *M*/35 *l*-amino-acid as (9) water, (10) aspartic acid, (11) glycine, (12) leucine, (13) valine, (14) γ-methyl-glutamic acid, (15) γ-methylene-glutamic acid. Nos. 16–22 contained 2 parts of extract, 1 part of *M*/35 oxalacetate and 1 part of *M*/35 *l*-amino-acid as (16) water, (17) alanine, (18) glycine, (19) leucine, (20) valine, (21) γ-methyl-glutamic acid, (22) γ-methylene-glutamic acid. Spots found at level *A* are aspartic acid, at level *B* are glutamic acid, and at level *C* are alanine

The experiments in which α-keto-glutarate was used were repeated, the glutamic acid produced being determined quantitatively after separation from the other amino-acids on chromatograms developed for 40 hr. in phenol – ammonia³. Similar experiments were performed in which the seed extract was replaced by an equal volume of an extract prepared

| | Per cent of the α-keto-glutarate converted to glutamic acid | |
|---|---|---|
| | Leaf extract | Seed extract |
| Alanine | 10·4 | 38 9 |
| Aspartic acid | 17·2 | 37·7 |
| γ-Methylene-glutamic acid | 8 8 | 56·5 |
| γ-Methyl-glutamic acid | 9·1 | 55 5 |
| Leucine | 4·0 | 9·6 |
| Glycine | 0·8 | 2·2 |
| Valine | 1·4 | 2·0 |

The leaf extract contained 0·49 mgm. total nitrogen per ml.; the seed extract contained 7·9 mgm. total nitrogen per ml.

in the same manner from the leaves of 20-day old plants. The percentages of α-keto-glutarate converted to glutamic acid in the presence of various amino-acids are given in the accompanying table.

The larger amounts of glutamic acid formed in the presence of the seed extract are probably only an indication that it contains higher concentrations of enzymes than those present in the leaf extract. The total nitrogen contents of the extracts give support to this idea. The transaminase system responsible for the conversion of the naturally occurring γ-methylene-glutamic acid is presumably also acting on the non-natural γ-methyl-glutamic acid, and since the rates of transamination are not significantly different for the two compounds, the affinity of the enzyme for the two substrates would appear to be unaffected by the differences in the groupings on the γ-carbon atom.

Our thanks are due to Miss A. E. Wright for technical assistance during part of this work.

## Effect of Enforced Exercise on Myoglobin Concentration in Muscle

For many years it has been widely accepted that active muscles are generally redder than those which are little used. Such differences might be regarded as fortuitous, however, and unconnected with the state of activity. The red colour is principally due to the presence of the pigment myoglobin[1]. To secure a convincing indication that myoglobin is increased as a result of muscular activity, its concentration has been compared in the muscles of forcibly exercised and of inactive rats. In addition, the effects of enforced inactivity on myoglobin concentration has been studied in the pectoral and leg muscles of domestic fowls.

Myoglobin was estimated by a method previously described[2] and *p*H by the glass electrode.

Table 1. Myoglobin in Relation to Enforced Exercise in Rats (mixed muscles of hind limbs)

| Group | No. of rats | Treatment | Myoglobin (% wet weight) | Sig. of diff. between means |
|---|---|---|---|---|
| *A* i | 6 | Unfed—exhausted | 0·094 ± 0·003 | nil |
| ii | 2 | Unfed—controls | 0·094 ± 0·009 | |
| *B* i | 3 | Fed—heavy exercise (1½ hr. 30 r.p.m.) | 0·097 ± 0·009 | nil |
| ii | 3 | Fed—heavy exercise (3 hr. 30 r.p.m.) | 0·105 ± 0·013 | |
| iii | 3 | Fed—controls | 0·096 ± 0·003 | |
| *C* i | 7 | Fed—trained (17 days, 2 hr./day) | 0·131 ± 0·006 | i > ii* |
| ii | 6 | Fed—controls | 0·104 ± 0·007 | |
| *D* i | 11 | Fed—trained (2 months, 2 hr./day) | 0·138 ± 0·006 | i > ii* |
| ii | 11 | Fed—controls | 0·111 ± 0·006 | ii > iii† |
| iii | 11 | Fed—'immobile' | 0·096 ± 0·006 | i > iii‡ |

* Significant at 5 per cent level. † Significant at 1 per cent level. ‡ Significant at 0·1 per cent level.

The effects of short bouts of exercise of varying severity were first considered. Female albino rats six months old of uniform breeding were made to run on mechanically driven drums at 30 r.p.m., corresponding to a running speed of 120 ft./min. In Table 1 (*A* i, ii), values are given for myoglobin levels in the mixed hind-limb muscles after the rats had been exhausted by 1½ hr. of this treatment. To accentuate the shock arising under these conditions, the animals were starved for 24 hr. prior to being placed in the machine. It may be seen that the pigment concentration in the muscles of the exhausted rats was not significantly different from that in the control animals, which were in cages. Nevertheless, the treatment had greatly lowered the glycogen reserves of the muscles in the exhausted rats, as their ultimate *p*H was 7·24 ± 0·04, whereas that in the controls was 6·46 ± 0·02. (The ultimate *p*H derives from the conversion to lactic acid of all the glycogen remaining in the muscle at death[3].) When well-fed rats were subjected to moderate exercise, there was again no change in myoglobin-levels (Table 1, *B* i, ii and iii). It was once more evident, however, that the enforced exercise had affected the muscles, as the ultimate *p*H in the controls was 6·20 ± 0·03, and in the exercised rats 6·90 ± 0·21 (1½ hr.) and 6·94 ± 0·15 (3 hr.).

As a stress of short duration apparently produced no change in myoglobin concentration, the effect of moderate exercise every day over an extended period (17 days) was considered. Seven rats were exercised for 2 hr. a day at about 10 r.p.m. A similar number were retained as controls. In Table 1 (*C* i and ii), it may be seen that this procedure led to an increase in myoglobin-levels in the treated animals which was significant at the 5 per cent level. In the hope of accentuating this trend, a further batch of female albino rats six months old were subjected to treatment. One-third of their number were trained for two months, again for 2 hr. a day and at 10 r.p.m. (Table 1, *D* i): one-third were retained as controls (*D* ii); and the remaining third were kept 'immobile' in a confined space (*D* iii). It is readily seen that myoglobin concentrations in the trained group were higher than those in both the controls and the 'immobile' animals, the significance of the difference being high—at the 0·1 per cent level. Furthermore, the values for the controls were also higher than those in the 'immobile' group, although the significance of this difference was not so great (1 per cent level).

The ultimate *p*H values of the muscles from the trained group (6·07 ± 0·04) were significantly lower than those in the controls (6·18 ± 0·03) and in the 'immobile' animals (6·16 ± 0·05), suggesting a building-up of glycogen during training. Changes of *p*H of this magnitude have been reported before in

Table 2. MYOGLOBIN IN RELATION TO 9 MONTHS ENFORCED INACTIVITY IN FOWLS

| Group | No. of fowls | Treatment | (% wet weight) | |
|---|---|---|---|---|
| | | | Myoglobin gastrocnemius | Pectoralis major |
| *A* | 10 | Normal activity | 0 177 ± 0·016 | 0·086 ± 0·001 |
| *B* | 10 | 'Immobile' | 0·116 ± 0·011 | 0 084 ± 0·001 |
| Significance of difference between means, at 0·1 per cent level | | | *A* > *B* | nil |

exercised rats, and the degree of acidity has been correlated with the quantity of lactic acid produced in the muscles[4].

The pectoral and leg (gastrocnemius) muscles of a group of fowls which had been allowed considerable freedom to forage, and of a comparable group closely confined in a battery over a period of nine months, were also analysed (Table 2).

Myoglobin concentrations in the gastrocnemius muscles of the normally active control group were significantly higher (0·1 per cent level) than those of the 'immobile' birds. It is interesting to note, however, that the pectoral muscles, which were not exercised by either group, showed no difference in pigment content.

It is concluded from these results that an increased myoglobin content represents one of the responses of muscle tissue to the influence of enforced activity, provided the latter continues over an extended period ('training'). Over a short period, even the most severe exercise elicits no such response, although it profoundly diminishes the glycogen reserves of the muscle.

I am indebted to Dr. D. G. Gilmour and Mr. R. W. Pomeroy, of the School of Agriculture, Cambridge, for making available the fowl muscles. The statistical analysis of the data in Tables 1 and 2 was carried out by the Statistical Laboratory, Mathematics Department, Cambridge. The interest shown in these experiments by Prof. D. Keilin and by Dr. E. C. Bate-Smith is gratefully acknowledged. The work described in this communication was carried out as part of the programme of the Food Investigation Organization, Department of Scientific and Industrial Research.

## Hyaluronidase as an Adjuvant to Methylene Blue in staining of Nerve Fibres

IT is notoriously difficult to produce consistent and uniform results in the vital staining of nerve fibres with methylene blue. Using Weddell's methods[1,2], both local and intravenous methylene blue in rabbits have given unsatisfactory results, with patchy and inconsistent staining.

Very considerable improvement in uniformity of staining of the nerve plexuses of the ear in rabbits has been achieved by adding hyaluronidase to the solution of the dye immediately before injection, in the proportion of 1,000 'Benger' units to 20 ml. of the dye solution. After local injection, diffusion of the dye throughout the corium and subcutis of the ear is rapid, particularly if the ear is lightly massaged. In other particulars, Weddell's method[1] has been followed.

Similarly, better staining is obtained after intravenous injection of methylene blue to which hyaluronidase has been added. Given intravenously, the enzyme appears to be relatively non-toxic; 6,000 units were added to the injection fluid in the case of a 2-kilo rabbit without apparent toxic effect. In all experiments the ordinary B.D.H. preparation of methylene blue was used as a 2·5 per cent solution in isotonic glucose. To prevent any possibility of saline over-dosage, the glucose solution has been used in preference to physiological saline as a vehicle for the dye. 20–30 ml. of the solution plus hyaluronidase were injected slowly over a period of 2–4 hr. The time factor is not significant. For examination of the nerve plexuses of the ear injection is made into one of the hind limb veins, as injection into the dorsal vein of the ear produces gross non-specific staining of the tissues around the site of injection from local diffusion of the dye.

Weddell[1] has pointed out the value of vasodilatation of the skin area being investigated, and certainly less uniform results in the ear are obtained when there is vasoconstriction. The induction of an acute inflammatory vascular reaction of the dorsal skin of the ear by rubbing with xylol during the injection period has produced the most consistent and uniform staining. This would suggest that uniformity of staining follows widespread capillary dilatation which reduces the need for tissue diffusion of the dye to the minimum.

The addition of hyaluronidase to the solution of methylene blue in supravital staining of nerve plexuses in human skin has also given promising results. An alternative to this method would be the injection of the enzyme locally into the skin before excision and supravital staining, since Bywaters *et al.*[3] have shown that the dermal barrier to the spread of dye after hyaluronidase injection is not reconstituted for 24 hr.

## The X-Organ of Crustacea

INTEREST in the location and identity of the *X*-organ of decapod crustaceans has been renewed with the discovery of its neurosecretory nature, for it is one of the major sources for the secretory material of the sinus gland[1-3]. The total endocrine complex formed by these two organs strikingly resembles the brain – corpora cardiaca complex of insects. The appearance of the *X*-organ varies in different species; but apparent homologues have been located in the nervous system of the eye-stalk of decapods by either of two methods: (*a*) from the original observation of Hanström[4,5] that it is usually associated with the innervation of the sensory pore

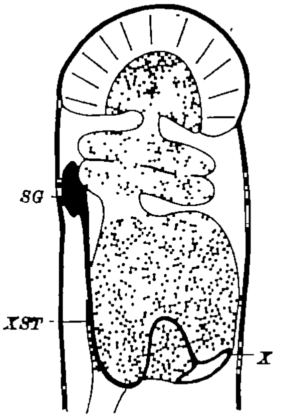

Fig. 1

or sensory papilla ; or (*b*) from the recent discovery[1–3] that the *X*-organ is linked to the sinus gland by the *X*-organ sinus gland tract, otherwise called the sinus gland nerve.

By examining a number of species of Crustacea (Stomatopoda : *Squilla mantis* ; Decapoda : Brachyura : *Carcinides* (= *Carcinus*) *maenas*, *Pachygrapsus marmoratus*, *Maia squinado*, *Uca pugilator*, *Portunus corrugatus*, *Dromia vulgaris* ; Anomura : *Calocaris macandreae* ; Natantia : *Crangon* (= *Crago*) *vulgaris*, *Lysmata seticaudata* ; Reptantia : *Palinurus vulgaris*) we have found that the *X*-organ in most forms contains at least three types of cell. In Brachyura, where the sensory pore is poorly developed or wanting, these different types of cells are commonly found together, usually at the proximal ventral corner of the medulla terminalis (Fig. 1) ; but in *Squilla* (Fig. 2) and in Natantia (Fig. 3) especially, the *X*-organ may be separated into two parts connected by a nerve.

In Brachyura, the most abundant cell type seems to be a big (30–40 µ diameter), pear-shaped, monopolar neuron, with a conspicuous nucleus and one to several nucleoli. The axon of this cell body is large, unbranched and leads to the sinus gland (Fig. 1). Secretory granules or droplets can be demonstrated by appropriate histological methods in both cell body and axon. These cell types are termed 'giant β neurosecretory cells'[2] or simply '*X*-organ neurosecretory cells'[1–3].

The second, and less-abundant, cell type in the Brachyura is a spherical cell (*c*. 15 µ in diameter), the nucleus of which lies against the cell wall, while most of the perinuclear space is usually filled by a single inclusion which stains uniformly. Sometimes several smaller inclusions are present instead. No axon can be seen. A third, and least abundant, cell type consists of oval or irregular 'concretions of concentric structure'[5] lying adjacent to both the cells types already described. No clearly defined nucleus can be seen in these bodies, which may be products of secretion rather than cells.

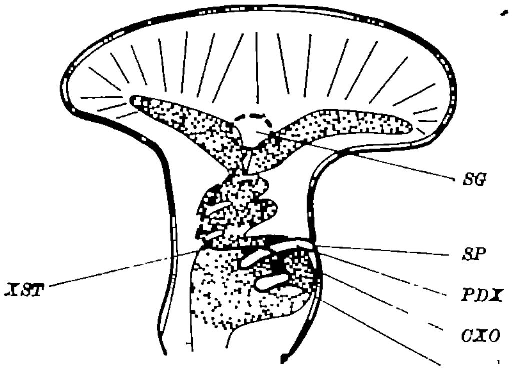

Fig. 2

In the Natantia examined, the two latter types of cell have been found close to the sensory pore. Cells of the second, spherical, type appear to be more numerous here than in the Brachyura, and they are characteristically ". . . shaped like a cluster of grapes surrounding the nerve from the medulla terminalis"[4]. These cells may form a syncytium. Cells of the first type (*X*-organ neurosecretory cells) are also present but are isolated from the other two kinds ; they occur in the medulla terminalis close to the point where the sensory pore nerve enters it. Fibres connect these two groups of cells.

In Natantia as well as Brachyura, the sinus gland is innervated by (and presumably receives secretory product from) the *X*-organ, but not from that portion of the *X*-organ close to the sensory pore. We propose that the two portions of the gland, where they are separated, should be termed ***pars distalis X-organi*** and ***pars ganglionaris X-organi*** (Figs. 2 and 3, *PDX* and *PGX*), while the nerve connecting them should be termed *connexio X-organi* (*CXO*), that is, *X*-organ connective.

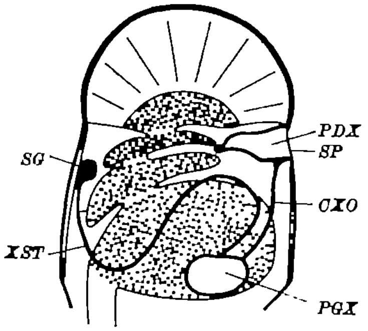

Fig. 3

*Dromia* and *Calocaris* show a degree of separation of these two portions of the *X*-organ intermediate between the extremes shown in crabs and shrimps.

We feel that these findings confirm the identification of the brachyuran *X*-organ by recent workers[1,2,6] and may explain why compatible results have not previously been obtained after *X*-organ extirpation in Natantia[7].

We wish to thank Dr. P. F. R. Dohrn for the *Calocaris* material placed at our disposal. One of us (D. B. C.) is aided by a grant from the Browne Fund of the Royal Society, and the other (L. M. P.) at present holds a National Science Foundation (U.S.A.) fellowship.

## Extension of the Salivary Chromosome Method to *Anopheles claviger, quadrimaculatus* and *aquasalis*

The cytogenetic method of investigation in malaria mosquitoes, based on morphological comparative study of salivary chromosomes, has been fruitful in the analysis of the *maculipennis* group. The results obtained are in good agreement with those of taxonomic studies based on egg morphology and larval chetotaxis; moreover, they permit systematic diagnosis also where such morphological differential characters vary too much or are altogether lacking. For example, where mixed *A. typicus* and *messeae* occur in a larval breeding place, no larval character is sufficient for their discrimination, whereas cytological examination shows different structures in the *X*-chromosome which are absolutely constant and characteristic of each species. The method of examination is both easy and rapid.

Hitherto, only species of the *maculipennis* group have been thoroughly investigated in our laboratory by this method, although we could foresee a much wider field of application. Preliminary researches in *A. claviger* showed this species to be a suitable one for cytogenetic studies.

Last year we received from Dr. L. E. Rozeboom a strain, easy to rear in laboratory conditions, of *A. quadrimaculatus*; the species, which is widespread in North America—middle and eastern States—is considered to be one of the chief malaria vectors. Cytogenetic study of this species, based on the structure of the salivary gland chromosomes, also appears possible and promising.

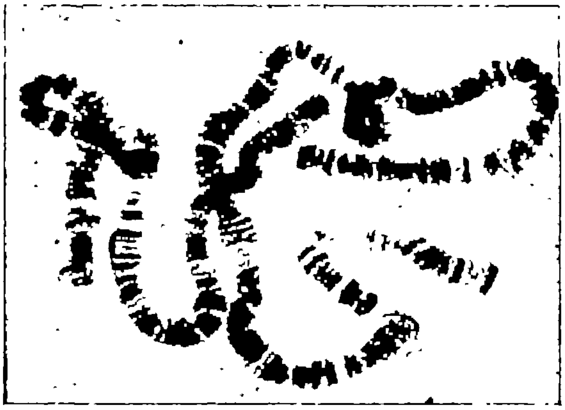
The mitotic chromosome picture consists of two mediocentric and one acrocentric, dot-like chromosomes, resembling those of *A. claviger* in somatic cells. Thus a preliminary investigation of the chromosomes of *quadrimaculatus* shows that the tip of one of them is similar to the end of the right arm of the third chromosome of the Italian *A. maculipennis*.

The end of the *X*-chromosome of *A. quadrimaculatus* also appears to be somewhat similar to that of *messeae*.

Any hypothesis on phylogenetic relationship between palearctic and nearctic forms of the *maculipennis* group has little foundation at present; but this cytogenetic approach is the most promising one for such investigation. The banding pattern of *freeborni* and *aztecus* is almost identical with that of *atroparvus*; there are, however, rather extensive inverted regions.

According to Freeborn, *quadrimaculatus* is a member of the *maculipennis* group, filling up a niche, in the United States, and completing "the globe encircling holoarctic distribution of this variable and versatile species". My preliminary results support this point of view. It must be admitted that the chromosomic set of *quadrimaculatus* resembles more closely that of *claviger* than *maculipennis*, in ordinary mitotic or meiotic cells; but I think the difference between *maculipennis* and *quadrimaculatus* could be referred to the heterochromatic part. As a matter of fact, the *X*-chromosome in the salivary gland cells is almost the same in the two species, although it appears rather different in the mitotic set. The phylogenetic relationship between nearctic and palearctic species, however, is a problem requiring much further investigation and close co-operation between many research workers.

What is unquestionable is the possibility of extending to the American species of the *maculipennis* group the same method of investigation as that applied to the Italian species. Comparing *freeborni*, *aztecus* and *occidentalis*, differences can be found in the chromosomic structures which make differential diagnosis easier in larval breeding places (for example, between *freeborni* and *punctipennis* in regions where these species are co-breeders).



Salivary gland chromosomes of *A. aquasalis* (subgenus *Nyssorhynchus*)

The species mentioned belong to the subgenus *Anopheles*. We believe that the method can be applied fruitfully also to species of the subgenus *Nyssorhynchus*. Dr. Ivan Ricciardi, of the Malariological Institute of Rio de Janeiro, has recently come to this Institute, and brought with him eggs and larvæ of *aquasalis*. Both in larvæ collected in Nature and in larvæ reared in the laboratory, the structure of salivary chromosomes appears with a clarity quite comparable to that characteristic of the most suitable species of *Drosophila* and *Chironomus* (see photograph).

We hope that complexes like *tarsimaculatus* and others of the subgenus *Nyssorhynchus* will offer suitable material for the application of the cytogenetic method.

## Probable Relationship between the *Rhodometopa* Group of Cercariæ and the Trematode Genus *Renicola* Cohn

During the past year, a study of the trematodes of the genus *Renicola* from birds in British zoos has been carried out and certain interesting points concerning the genus have come to light.

Among other features to which particular attention was given is the excretory vesicle in a species which has been found on several occasions in the kidneys of various penguins. This species was first reported by Campbell and Sloane[1] from king penguins in the Edinburgh Zoo. The fact that they had found specimens in birds hatched in the menagerie, and certain other features of infections observed in London, seemed to indicate that this is not a normal parasite of penguins, but is more likely to be found in British sea-birds. With this in view, a search was started and, after several unsuccessful examinations about ten specimens, similar to those from the penguins, were found in the kidneys of a common guillemot (*Uria aalge*).

An examination of the literature on larval trematodes from British marine gastropods showed almost at once the very marked similarity between the excretory vesicle of young adults of this species of *Renicola* and that of the *Rhodometopa* group, of cercariae, particularly *C. pythionike* Rothschild[2]. In both cases the vesicle is *Y*-shaped with numerous lateral branches and with a connecting channel joining the two arms of the *Y* immediately behind the ventral sucker.

Evidence of this kind seems fairly strong, and further work is being carried out in the hope that a knowledge of the larval stages may help to establish more definitely the true systematic position of this somewhat disputed genus.

# Relationship between the Oxidative and Fermentative Phases during Adaptation to Galactose in *Saccharomyces cerevisiae*

Aerobic adaptation to the utilization of galactose in *Saccharomyces cerevisiae* occurs in two phases: an oxidative phase in which the respiratory quotient is 1, and a fermentative phase which follows it[1]. Further experiments have now demonstrated that during the oxidative phase of adaptation to galactose, the yeast cells are capable of fermenting galactose if anaerobic conditions are introduced. The degree of fermentation which resulted when anaerobic conditions were instituted was found to be correlated with the degree of adaptation during the oxidative phase as measured by the $Q_{CO_2}$.

These results confirmed previous ones which indicated that adaptation to the utilization of galactose is not concerned with oxidation or fermentation as such, but rather with an enzyme or series of enzymes which make galactose available to the cell for subsequent oxidation or fermentation[1]. Since the oxidative phase of aerobic adaptation was always followed by the onset of fermentation, provided the concentration of galactose was sufficiently high, it was of extreme interest to determine the factors involved in this shift from oxidation to fermentation under aerobic conditions.

It was found that, during the early stages of adaptation long before fermentation started, carbohydrate was being stored, some as glycogen and some as glycolytic intermediates, and pyruvate did not accumulate appreciably until storage of glycolytic intermediates was close to maximum. Therefore, it appears that storage occurs as soon as adaptation starts, and that only a relatively small amount of galactose is initially metabolized to pyruvic acid and oxidized through the tricarboxylic acid cycle. However, when storage is at a maximum and adaptation has proceeded sufficiently, galactose is metabolized at a greater rate to pyruvate until the oxidative mechanisms are apparently saturated, and pyruvate and acetaldehyde accumulate. It is at this point that fermentation starts. These conclusions are in agreement with previous results which demonstrated that, at low concentrations of galactose, adaptation occurred readily (as indicated by increase in $Q_{O_2}$, disappearance of galactose, and accumulation of glycogen) but that fermentation did not occur[1].

An important implication of these results is that fermentation is not a valid criterion for measuring the synthesis of the galactose-adaptive enzyme. The onset of galactose fermentation in yeast appears to be dependent upon the preliminary accumulation of reserves and intermediates, and only in a superficial way related to the kinetics of adaptive enzyme formation. Therefore, experiments using this method which purport to show that the synthesis of galactokinase is autocatalytic in nature are invalid[2], and theories which postulate the existence of extrachromosomal hereditary factors in order to explain the kinetics of galactokinase formation in yeast[2] are premature.

I wish to thank Dr. Carl C. Lindegren for encouragement during the progress of the work. This work has been supported by grants from the American Cancer Society, administered by the Committee of Growth, National Research Council, National Cancer Institute of the National Institutes of Health, Public Health Service and Anheuser-Busch, Inc.

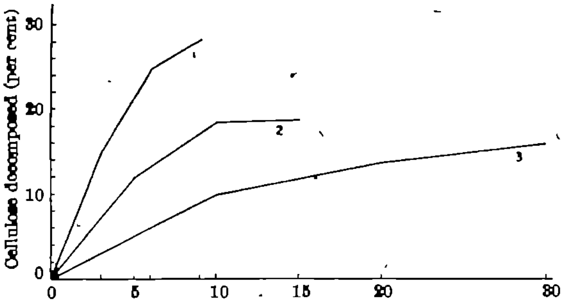
# Purification and Cellulolytic Activity of *Cellvibrio*

In recent years, several workers have paid a great deal of attention to the purification and the cellulolytic activity of aerobic cellulose-decomposing bacteria, especially *Cytophaga* and *Cellvibrio*. Isolations have generally been carried out by direct plating of soil suspensions on precipitated cellulose agar, and by enrichment cultures on silica-gel filter paper or on filter paper partly immersed in a liquid mineral medium. With the former method, most of the dishes are invaded by moulds and generally the formation of lytic zones is not very obvious.

In order to isolate *Cellvibrio*, a first enrichment was effected on silica-gel filter paper. After tenfold subculturing on the same medium, impurities in the form of other bacteria were still present. The impure strains were plated out on precipitated cellulose agar containing the common minerals, 0·1 per cent farmyard manure extract and 0·2 per cent cellulose. After seven days incubation at 26° C., different types of colonies were obtained. Some were surrounded by clear lytic zones while other colonies were not. All the *Cellvibrio* colonies that produced lytic zones on this medium showed a luxuriant growth when subcultured on filter paper agar. The strains obtained in this way were again plated on cellulose agar until only one type of colony with clear lytic zones was present. These strains were considered to be absolutely pure.

Not all strains of *Cellvibrio*, after enrichment on filter paper, produced lytic zones on precipitated cellulose agar to which farmyard manure extract was added. Some strains need other growth factors in addition to those present in the farmyard manure extract. More work will be done on the role of these factors in the formation of lytic zones by *Cellvibrio* on cellulose agar.

The pure cultures already have been maintained during four months by alternate subculturing on agar filter paper and precipitated cellulose agar provided with farmyard manure extract.



Vibrio 14: (1) pure strain on agar cellulose; (2) impure strain on agar cellulose; (3) impure strain on cellulose and mineral liquid medium

Impure strains, after many subcultures on silica-gel paper medium, and pure strains obtained by using the technique mentioned above, were tested for cellulolytic activity. We used two methods: growth in square-section bottles on a liquid mineral medium to which filter-paper strips were added, and a mineral agar medium covered with filter paper. Farmyard manure extract was not present in either media. The cellulose decomposition was measured by loss of dry-weight of the filter paper. The accompanying graph shows the results with an impure and a pure strain of *Cellvibrio* 14 on the two media.

It seems clear that the cellulose is more rapidly decomposed in the early stage of growth on the agar filter medium. The pure strain is also more active than the impure one.

Further results with other pure strains of *Cellvibrio* will be published elsewhere.

## Some Factors affecting Heat Tolerance of Cattle and Buffaloes

EGYPTIAN cattle, buffaloes and high-grade shorthorns were used for studying the effect of age, lactation and fattening on heat tolerance coefficients. The method developed by Rhoad[1] was used in estimating the heat tolerance, and the test was carried out twice during July 1952. The atmospheric temperature during test days ranged between 91° and 98·6° F., and relative humidity between 42 and 68 per cent. The average body temperatures of animals during March 1950 were taken as normal body temperature[2].

It was found that calves one year old had the lowest adaptability coefficient (see table). As young calves are sensitive organisms, probably their heat-regulating mechanisms are not as efficient as that of older animals.

HEAT TOLERANCE COEFFICIENTS OF EGYPTIAN CATTLE, BUFFALOES AND SHORTHORN GRADES AT DIFFERENT AGES

| Animals | Age | No. of animals | Heat tolerance coefficient | |
|---|---|---|---|---|
| | | | Rhoad's test | One reading |
| Egyptian cattle | Mature (lactating) | 4 | 80·4 | 80·3 |
| | 2 years | 8 | 84·1 | 83·5 |
| | 1 year | 8 | 78·5 | 77·9 |
| Buffaloes | Mature (lactating) | 10 | 69·5 | 66·0 |
| | 2 years | 9 | 71·8 | 67·7 |
| | 1 year | 10 | 64·1 | 59·2 |
| Shorthorn grades | Mature (lactating) | 9 | 72·0 | 71·0 |
| | 2 years | 8 | 74·8 | 73·5 |
| | 1 year | 10 | 62·0 | 61·2 |

Our results show that lactating animals are less tolerant than animals two years of age. It should be noted that mature animals used in this work were during their first month of lactation. Such animals consume more food than two-year old heifers and consequently their heat increment is increased; moreover, the endocrine and mammary glands of lactating animals are more active than non-lactating ones. These factors are responsible for increasing the body temperature of lactating animals and lead to a lower heat tolerance coefficient. The heat tolerance coefficients of non-lactating Egyptian cows, buffaloes and shorthorn grades have been found[3] to be 91·5, 75·7 and 89·2 per cent respectively; these are higher than those reported here for lactating animals and heifers two years of age.

To study the effect of fattening on the heat tolerance coefficient of buffalo calves, a group of three calves were given a rich ration of concentrates after weaning until they were eleven months of age. These calves gained about 1·5 lb. daily, while the control group gained only 0·7 lb. The average heat tolerance coefficient of the fattened group was 60 per cent compared with 64 per cent for the non-fattened ones. This difference may be attributed to the fact that fattened calves consumed three times as much food as that taken by the control animals, and consequently their heat increment should be greater than that of the controls. Deposition of more fat under the skin of fattened calves may be another factor in decreasing their heat tolerance.

The Iberia heat tolerance reported by Rhoad[1] requires that the body temperature of tested animals be recorded at 10.00 a.m. and 3.00 p.m. for three hot days (atmospheric temperature close to 90° F.). During the course of this experiment, body temperatures of animals were taken at 12.30 p.m., and heat tolerance coefficients were calculated using this reading only. It is interesting to note that the two estimates obtained are very close except in the case of buffaloes (see table). Work carried out in this department has shown that the body temperature of buffaloes increased with increasing the period of exposure to summer sun; whereas Egyptian cattle and graded shorthorns were not significantly affected[2]. This is probably the explanation of the discrepancy between the estimates obtained for buffaloes.

When individual heat-tolerance tests were calculated for each animal, it was found that there were significant differences between individuals of the same age. Some of the buffalo one-year old calves had to be removed during hot hours on test days. Highly tolerant animals should be selected for breeding, as such animals are more efficient in food utilization and production.

This work was carried out at the Animal Breeding Department, Faculty of Agriculture, Giza, Egypt.

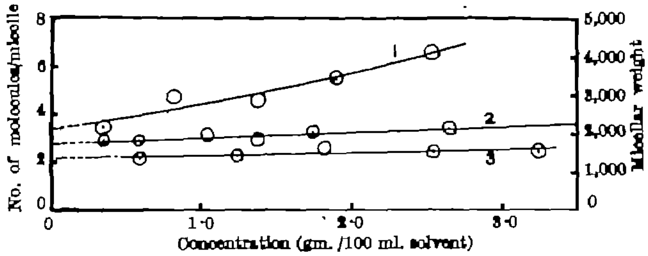
## Dipole Moments of Metal Oleates

Banerjee and Palit[1] have reported a value of 0·29 D. for the dipole moment of zinc oleate in contrast to values of 1·20 and 1·66 D. for the oleates of copper and magnesium. A possible reason for this anomaly has been found in the course of an ebullioscopic investigation of the micellar weights of some of the metal soaps in benzene and other solvents.

The dipole moments reported by Banerjee and Palit were evaluated by measuring the molar polarization of the oleates in benzene solution, using a heterodyne beat method. This procedure is based on the fundamental assumption that the solute is either molecularly dispersed or is approaching molecular dispersion in the concentration range in which the polarization measurements are made. Micellar weight data for zinc oleate, however, are shown in the accompanying graph.



Micellar weight and degree of association of zinc oleate in organic solvents: (1) benzene; (2) toluene, (3) $p$-xylene

These results demonstrate the presence, in all the solutions, of aggregates at concentrations well below those at which Banerjee and Palit made their polarization measurements. Further, the shape of the micellar weight-concentration curves provides no justification for the assumption that extrapolation of the polarization data to infinite dilution is likely to give a reliable value for the polarization of the molecularly dispersed solute. Aggregation was also detected ebullioscopically in solutions of the copper and magnesium compounds; but, in these cases, the accuracy obtainable did not warrant extrapolation of the micellar weight data to infinite dilution. The fact hat aggregation occurs in all these solutions even at low concentrations suggests that the absolute values of the moments reported by Banerjee and Palit may be in error, although there is little reason o doubt that their measurements place the oleates in the correct order of polarity.

It should be noted that Banerjee and Palit's measurements were made at room temperature, whereas the micellar weight measurements now eported are at the boiling points at atmospheric ressure of the respective solvents. However, a omparison of the micellar weights of zinc oleate in enzene (boiling point 80·1° C.) and $p$-xylene (boiling point 138·4° C.) indicates clearly that, at room emperature in benzene, aggregates even larger than hose observed at the boiling point are to be expected. The measured micellar weights are average alues, and a high average micellar weight in solution does not therefore exclude the presence of some micelles of smaller size, or even of some molecularly dispersed solute. The measured polarizations are hus mean values for the different sizes of particles resent in the solutions. Since the larger aggregates ight reasonably be expected to be much less polar, he relatively high polarization values recorded by Banerjee and Palit provide evidence for the existence in the solutions of some particles considerably smaller than the average and possibly also for a small proportion of the monomeric solute. The ebullioscopic apparatus used in these experiments has been described elsewhere[2].

## Optical Exaltation in Aromatic Compounds

It is known that the molecular refraction, as defined by Lorenz–Lorentz, of liquid (non-aromatic and non-conjugated) organic compounds may be calculated with fair accuracy by summation of the atomic refractions and the contributions to structural influences which may play a part (for example, olefinic double bonds). For aromatic compounds this additive character of the molecular refraction does not apply. Here the value measured is nearly always greater than the sum of the atomic refractions and contributions due to double bonds.

In determining the molecular refraction, the difficulty is encountered that, under normal conditions (20° C.), most of the aromatic compounds with three or more rings are solids, some of which have a very high melting point. This difficulty may be avoided by dissolving compounds the molecular refraction of which is required in a solvent with a known molecular refraction, determining the refractive index and the density of the solution, and afterwards calculating the molecular refraction of the solution from these results. The molecular refraction of the dissolved substances as a hypothetical liquid is denoted by:

$$R_{M_{\rm I}} = \frac{R_{M_{\rm I\,II}} - f_{\rm II} \cdot R_{M_{\rm II}}}{f_{\rm I}}, \qquad (1)$$

where $R_{M_{\rm I}}$ and $R_{M_{\rm II}}$, $R_{M_{\rm I\,II}}$ are molecular refractions of the dissolved substance, the solvent and the solution respectively; and $f_{\rm I}$ and $f_{\rm II}$ are molecular fractions of the dissolved substance and the solvent respectively. The molecular refractions of a number of aromatic compounds in the hypothetical liquid state at 20° C., calculated in this manner, are given in the accompanying table.

With the help of the values of the molecular refractions determined, we derived the corresponding refractometric exaltations (see table). Here the exaltation of an aromatic $C_pH_qO_rN_sS_t$ molecule is defined as:

$$E = R_M - (p.R_C + q.R_H + r.R_O + s.R_N + t.R_S), \qquad (2)$$

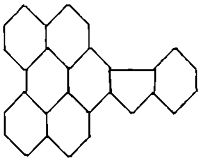
where $R_M$ is the measured molecular refraction of the compound; $R_C$, $R_H$, $R_O$, $R_N$ and $R_S$ are the atomic refractions of C, H, O, N and S, as derived from non-aromatic compounds. For the atomic refractions we used those which may be calculated from the bond refractions given by Vogel *et al.*[1]. $p$, $q$, $r$, $s$ and $t$ are the number of C, H, O, N and S atoms.

| Compound | Formula | *RM* | *E* | *E/A* |
|---|---|---|---|---|
| Acenaphthene | $C_{12}H_{10}$ | 52·0 | 10·6 | 1·06 |
| Fluorene | $C_{13}H_{10}$ | 54·7 | 10·7 | 0·89 |
| Acridine | $C_{13}H_{9}N$ | 63·8 | 18·4 | 1·31 |
| Anthracene | $C_{14}H_{10}$ | 65·6 | 18·9 | 1·35 |
| Phenanthrene | $C_{14}H_{10}$ | 62·2 | 15·5 | 1·10 |
| Pyrene | $C_{16}H_{10}$ | 72·5 | 20·7 | 1·29 |
| Fluoranthene | $C_{16}H_{10}$ | 71·5 | 19·7 | 1·23 |
| Brazan | $C_{16}H_{10}O$ | 75·8 | 22·3 | 1·31 |
| 2,3 Benzfluorene | $C_{17}H_{12}$ | 77·2 | 20·8 | 1·22 |
| Chrysene | $C_{18}H_{12}$ | 83·4 | 24·4 | 1·36 |
| 1,2 Benzanthracene | $C_{18}H_{12}$ | 82·6 | 23·6 | 1·31 |
| Hexahydroperylene | $C_{20}H_{18}$ | 90·0 | 17·6 | 1·26 |
| 1,2,5,6 Dibenzanthracene | $C_{22}H_{14}$ | 104·9 | 33·5 | 1·52 |
| Coronene | $C_{24}H_{12}$ | 107·2 | 32·7 | 1·36 |
| Difluorenyl | $C_{26}H_{18}$ | 108·0 | 22·1 | 0·92 |
| β Truxene | $C_{27}H_{18}$ | 114·9 | 26·4 | 1·10 |

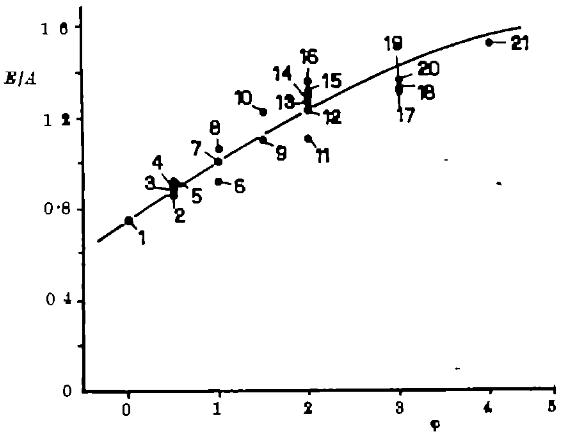
Now it appeared that the optical exaltation per aromatic atom (*E/A*) is far from constant, it being a function of a structure parameter Φ, which we define as:

$$\Phi = r_{ar} - \frac{3}{2} i_{ar} + \tfrac{1}{2} j, \qquad (3)$$

where $r_{ar}$ is the number of aromatic joint bonds between aromatic 6-rings, $i_{ar}$ is the number of buried carbon atoms (completely enclosed by aromatic 6-rings), and $j$ is the number of direct covalent bonds between aromatic 6-rings (non-condensing). For example, the parameter Φ for the molecule



is given by $\Phi = 9 - \frac{3}{2}\,4 + \frac{1}{2}\,.\,1 = 3{\cdot}5$ because $r_{ar} = 9$, $i_{ar} = 4$ and $j = 1$. The value of the structure parameter Φ is linked up with the geometrical asymmetry of the molecule. The correlation between the exaltation per aromatic atom *E/A* and the structure parameter Φ is given in the accompanying graph. This correlation has been given a theoretical foundation.



1, Benzene; 2, 2,3′ dimethylbiphenyl; 3, fluorene; 4, 3,4′ dimethylbiphenyl; 5, 1 methyl 2 phenyl 4 isopropylbenzene; 6, difluorenyl; 7, naphthalene; 8, acenaphthene, 9, β truxene; 10, 2,3 benzfluorene; 11, phenanthrene; 12, fluoranthene; 13, hexahydroperylene; 14, pyrene; 15, acridine; 16, anthracene; 17, 1,2 benzanthracene; 18, brazan; 19, chrysene; 20, coronene; 21, 1,2,5,6 dibenzanthracene

With the help of this correlation, it is possible to draw conclusions as to the structure of mineral fuels. Particulars about this correlation and about the method followed in the structural investigation will be published elsewhere.

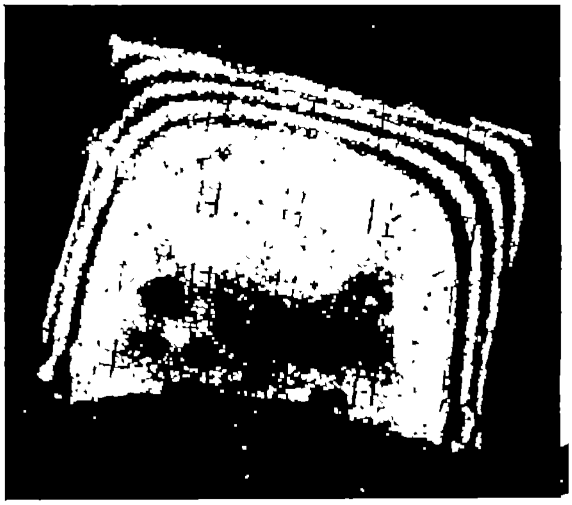
## A New Method of making Electron Microscope Specimen Support Films

It has been found that a thin film, suitable for specimen mounting, is formed over the mesh squares of an electron microscope specimen grid when dipped into a 1 per cent solution of 'Formvar' in chloroform, and allowed to dry in air. Very thin films, which are stronger than those wet-stripped from glass, can easily be obtained.

In each grid square, the film is uniformly thin over the central 70–80 per cent of the total area, thickening abruptly at the edges.

The accompanying photograph was taken by Mr. J. Dyson of this laboratory on an interferometer microscope[1] at a magnification of 500 diameters. The interference fringes can be regarded as contour lines of equal thickness. To make the photograph possible, it was necessary to cut across a grid in order to leave half the field free for the interfering beam. This required a thicker film than is usually made for the electron microscope; consequently, the uniform area is somewhat reduced. The loss in usable area is offset by the advantages that the films are easily and quickly made, entirely free from dirt and very rigid on the supporting grid.

A disadvantage arises when metal shadowing at small angles, because the vertical position of the film lies between the top and bottom of the grid bars; hence part of the area of each grid square is not shadowed. At angles of $\tan^{-1} \frac{1}{2}$ and $\tan^{-1} \frac{1}{3}$, shadowing generally covers the entire film.



Interference photograph of cut 'Formvar' film

To make the film, the specimen grid is held at the extreme edge in a fine-pointed pair of forceps, and immersed in the solution. On withdrawal, it is held horizontal and allowed to dry; this takes only a few seconds. The formation of the film is easily observed during drying, and best results are obtained when up to about one-third of the grid squares remain covered. If the whole grid is covered, the film is usually found to be too thick. To achieve this, two factors can be varied. The strength of solution can be between 0·5 and 1 per cent, and the amount of liquid remaining on the grid can be varied by the manner in which it is withdrawn from the solution. With practice, good thin films can be made without difficulty. It is important to remove the grid from the forceps immediately after the drying of the film is complete, otherwise any solution remaining on the forceps will form a thick blob of 'Formvar' on the grid which is liable to charge up electrically in the microscope. It is convenient to transfer the grid quickly to a second pair of forceps and remove any small drops of liquid which may remain at the point where it was previously gripped.

The method has been used over a period for routine work and has proved to be very satisfactory.

I wish to thank Dr. T. E. Allibone for permission to publish this note.

## Frictional Electrification of Polar Polymers

IT does not appear that any single mechanism suffices to explain frictional electrification completely[1,2]. The electrolytic mechanism of charge transfer has been discussed by Freundlich[3], but is generally taken to presuppose the existence of thin aqueous films on the surfaces, and to have only limited application to 'dry' solids[3]. Further, the conductance of even the thinnest of aqueous films is likely to suppress electrification on separation[4]. Nevertheless, electrolytic action accounts very satisfactorily for the behaviour of solids with polar properties. Thus Knoblauch[5] demonstrated the tendency of a large range of acids and bases to become electrified negatively and positively respectively, and obtained the best results with organic acids and bases. One concludes that the polar nature of these substances facilitated ionic processes in the presence of sorbed water molecules (not necessarily forming a separate phase), and that the acid donated excess positive ions (proton) and bases excess negative ions (hydroxyl). The results no doubt depend on the relative mobility of the ions, the larger ions tending to aggregate in both cases and were therefore less mobile than H$^+$ and OH$^-$ ions.

Excellent conditions for investigating electrolytic charge separation obtain with polar polymers, and in particular textiles and ion-exchange resins. The presence of the acid or basic groups promotes water sorption and consequent ionic dissociation and mobility even at low humidities[6]. One ion is, however, firmly bound to the polymer matrix and the other is free to take part in the charge transfer. For example, consider the strongly basic resin 'De-acidite *FF*', and the strongly acid 'Permutit' sulphonated polystyrene. We have:

$$R.\mathrm{NOH} \rightarrow R\mathrm{N}^+ + \mathrm{OH}^-$$
$$R.\mathrm{SO_3H} \rightarrow R\mathrm{SO_3}^- + \mathrm{H}^+,$$

with the respective positive and negative ions firmly bound; the resins donate freely diffusible OH$^-$ and H$^+$ ions respectively. This was indeed found to be true at about 30 per cent relative humidity, when the resins in powder form were shaken from a filter paper; the basic resin showed consistent positive charges and the acid resin negative charges.

Weak bases and acids were found to behave in a similar manner provided they were carefully neutralized (for example, 'Amberlite' *IR 4B* and 'Zeo-Karb' 216). It would seem that a similar mechanism also contributes largely to the electric charge acquired by wool keratin, which becomes positively electrified against filter paper; this is characteristic of polypeptides, which contain both basic and acidic groups against cellulose. Acidified horn keratin also becomes positively electrified against filter paper, while after treatment with dilute caustic soda it becomes negatively electrified. Similar reversals may be obtained with the resins, and in all these cases the direction of charge transfer is given by the sign of the boundary potential as deduced from the Donnan theory.

## A New Precision Method for the Measurement of Ultrasonic Velocities in Liquids

SEVERAL methods[1] are available for the determination of ultrasonic velocities in liquids, of which the liquid film method[2] offers many advantages. The new method presented here enables a rapid determination of ultrasonic velocities with a high degree of accuracy.

The experimental arrangement consists of the usual apparatus for observing the Debye–Sears diffraction pattern in liquids. A quartz *X*-cut wedge of 1–3 Mc./sec. range is mounted in the crystal holder with *X*-axis vertical and the tapered edge parallel to the direction of the light beam, and is excited by a Hartley shunt-fed oscillator. The ultrasonic waves generated by this wedge are communicated to the liquid contained in a glass cell mounted on a levelling stand. The levelling is then adjusted so that the bottom of the glass cell is truly parallel to the surface of the wedge in contact with the liquid. A stationary ultrasonic diffraction grating can now be set up in the liquid column only at those frequencies for which the liquid column is in resonance.

Intense diffraction patterns are observed at a large number of these frequencies, which are very closely spaced. Using a slow-motion gear on the oscillator condenser and a length of liquid column of 4 cm., the frequencies of a number of these diffraction maxima have been measured and found to be exactly equally spaced, the frequency difference being in the range of 0·01–0·03 Mc./sec. for various liquids. The frequency difference $\Delta f$ between any two consecutive maxima is obtained by measuring the frequency interval for about a hundred maxima. The ultrasonic velocities are then evaluated by using the relation

$$V = \Delta f \times 2L,$$

where $L$ is the length of the liquid column and $V$ is the velocity of ultrasonic waves in the liquid. Results thus obtained for the velocities of ultrasonic waves in some liquids are shown in the accompanying table.

| Liquid | $L$ (cm.) | $\Delta f$ (Mc./sec.) | $V$ (m. per sec.) (20° C.) |
|---|---|---|---|
| Amyl alcohol | 3·3 | 0·0202 | 1,333 |
| Benzene | 4·0 | 0·0162 | 1,296 |
| Carbon tetrachloride | 3·9 | 0·0117 | 913 |
| Toluene | 3·7 | 0·0176 | 1,302 |
| Water | 5·0 | 0·0151 | 1,510 |

These values for the ultrasonic velocities are found to be in good agreement with those obtained by other methods. The accuracy of the results obtained is about 0·2 per cent. A higher accuracy of 0·02 per cent can be achieved with a precision wavemeter and thermostatic control of temperature of the liquid.

Though the method is simple, accurate and rapid, it is limited to transparent liquids and is not suitable for measurements at very high frequencies.

Further investigations are in progress. An interferometric modification of this method with a movable layer of mercury in the bottom of the ultrasonic cell as reflector is also under investigation.

## Structure of Magnesium–Lithium β-Phase Alloys

During work on magnesium–lithium–silver alloys, Hume-Rothery, Raynor and Butchers[1] examined X-ray powder photographs from binary magnesium–lithium alloys containing the body-centred cubic β-phase, or a mixture of this phase with the close-packed hexagonal magnesium-rich α-phase. Diffraction patterns from (α + β) alloys showed, in addition to fundamental reflexions, extra lines which were provisionally identified as derived from an $Fe_3Al$ type of superlattice in the β-structure. The extra lines persisted on annealing at temperatures up to 300° C. and were also present in diffraction patterns of thin rods quenched from 420° C., but were not observed in photographs from homogeneous β-alloys. It was suggested that the β-phase develops an $Fe_3Al$ type of superlattice very near to the (α + β)/β boundary. The existence of such a structure in a system of two components of such similar atomic size and electrochemical characteristics is surprising, but no further examination of the phenomenon was possible. More recently, however, the original diffraction patterns became available for re-examination; inconsistencies in the development of the suspected superlattice at various temperatures were noted, while identification of the extra lines with $Fe_3Al$-type ordering appeared uncertain. The appropriate region of the binary diagram has therefore been re-investigated.

| Alloy No. | Atomic % lithium | Annealing treatment | Phases present | Remarks |
|---|---|---|---|---|
| 1 | 34·0 | Quenched after 24 hr. at 400° C. + 24 hr. at 200° C | β | Cast from under lithium chloride flux |
| 2 | 23·0 | 14 days at 420° C. followed by slow cooling to room temperature at 50 deg./day | α + β | Cast in argon, using the method of Hume-Rothery, Raynor and Butchers (ref. 1) |
| 3 | 32·7 | | α + β | |
| 4 | 22·1 | Quenched after 14 days at 400° C. + 21 days at 200° C. | α + β | Cast in argon with improved technique, using iron crucibles |
| 5 | 27·7 | | α + β | |
| 6 | 31·86 | | β | |
| 7 | 33·62 | | β | |
| 8a | 49·4 | Quenched after 48 hr. at 400° C. + 24 hr. at 300° C. | β | Cast from under lithium chloride flux |
| 8b | 49·4 | As for alloys 2 and 3 | β | |

The alloys used in the structural investigation are described in the accompanying table.

Exploratory experiments were carried out with alloy 1. The diffraction pattern, obtained in a 19-cm. powder camera with copper $K_\alpha$ radiation, showed a number of weak lines additional to the fundamental reflexions. The photograph could not be satisfactorily indexed in terms of an ordered structure of the $Fe_3Al$-type. Measurement of nineteen of the extra lines ($\theta = 8°$ to $\theta = 32°$) indicated, however, that they could be indexed on the basis of an ordered cubic structure of lattice spacing $a_0 \simeq 9·7$ kX. Further reference to this is made below. Alloys 2 and 3 both gave rise to diffraction patterns containing extra lines which, however, did not correspond with those from alloy 1, and could not be indexed in terms of any simple structure, or with any simple ordered arrangement based on either the α- or β-phases.

From this lack of consistency it was suspected that the extra lines in alloys 2 and 3 might be associated with the presence of contaminants introduced during the preparation of the reactive alloys. The most likely cause of contamination is reaction of the molten metal with the atmosphere or with residual atmospheric impurities in the argon. A deliberately contaminated specimen was therefore obtained by heating a binary alloy in air until a considerable amount of reaction product (oxide and nitride) had accumulated. By comparison of this material, using monochromatized copper radiation in conjunction with a Geiger-counter spectrometer, with alloy 3 it was shown that the extra lines in the diffraction pattern of the latter from $\theta = 10°$ to $\theta = 35°$ corresponded exactly to the stronger lines in the pattern of the oxidized specimen. Further comparison showed that the extra lines on films obtained during the original work also corresponded with the stronger diffraction lines of the oxidized alloy. These experiments indicated that the apparent coincidence of the diffraction patterns in the original work with an $Fe_3Al$ type of structure was fortuitous, and that the extra lines were due to contamination.

To test this conclusion, alloys 4–7 were prepared under more stringently controlled conditions. Since the use of alumina crucibles leads to contamination

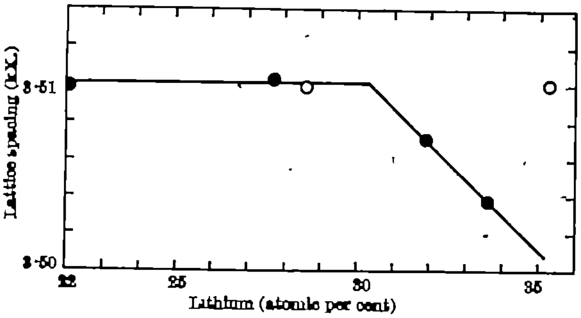

Fig. 1. ●—●—, iron crucible; O—O—, alumina crucible

by aluminium, the metals were melted in iron crucibles under argon which had been passed through a considerably enlarged purifying train to remove oxygen, nitrogen and water. Minimum preparation times were employed; the crucible was raised to the casting temperature before inserting the magnesium, and the lithium was added to the molten metal from a wire cradle without opening the apparatus. Casting also took place in the same enclosed apparatus, and the alloys were adequately protected from the atmosphere at all stages. The diffraction patterns showed only a few extra lines, of intensity considerably less than those observed for alloys 1–3. The few extra lines corresponded exactly with the strongest lines in the pattern of the oxidized specimen; their intensities did not vary with the amounts of α and β present. The striking reduction in the number and intensity of the extra lines by greater care in alloy preparation confirms that the effects arise from contamination, and not from superlattice formation.

Fig. 1 shows the lattice spacings (kX. at room temperature) obtained from the second series of alloys. For comparison, two measurements made on alloys prepared in alumina crucibles are included; one of these is clearly inconsistent with the results for alloys 4–7. The (α + β)/β boundary at 200° C. deduced from Fig. 1 lies at 30·3 atomic per cent lithium, which is not consistent with the extrapolation of the boundary reported at higher temperatures by Catterall[2].

As noted above, the diffraction pattern for alloy 1 indicated the presence of both the β-phase and a cubic structure of unit-cell side approximately 9·7 kX. The systematic absences and the relative line intensities may be accounted for by a structure with hirty-two atoms per unit cell as illustrated in Fig. 2. t is significant that the lattice spacing is nearly equal to $2\sqrt{2a}$, where $a$ is the lattice spacing of the body-centred cubic β-structure. In the basal plane (001) the atomic sites and distances are closely imilar to those in the (001) plane of the β-structure; thus the new structure may be regarded as formed by an expansion of the [001] direction in the cubic structure by a factor of $\sqrt{2}$, accompanied by ordering.

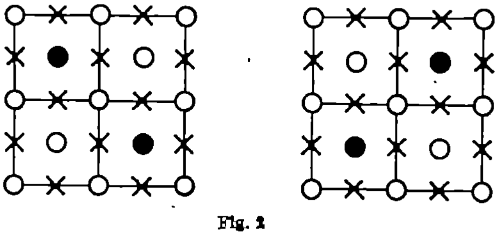

Fig. 2

○, Li } at heights 0 and $a$
●, Mg }
×, Mg at heights $a/4$ and $3a/4$

○, Li } at height $a/2$
●, Mg }
×, Mg at heights $a/4$ and $3a/4$

It is thus equivalent to a body-centred cubic arrangement, in which cube corners and two cube centres out of every eight are occupied by magnesium and the remaining sites by lithium, which has been stretched out vertically. This structure was not observed in the slowly cooled alloys 2 and 3, nor in the uncontaminated alloys 4–7, and is probably to be regarded as a transitional structure due to relatively short annealing times, and stabilized by impurities (oxygen and nitrogen).

It is of interest to note that alloy 8*a*, after comparably short annealing times, also showed a number of extra lines, which were almost completely absent from the diffraction pattern of alloy 8*b*. Such extra lines as were observed gave no indication of ordering near the equiatomic composition.

The new evidence available suggests strongly that no ordered structures exist at equilibrium in (α + β) alloys, or in alloys of composition in the range 30–34 atomic per cent of lithium, while no evidence for ordering at 50 atomic per cent lithium has been obtained.

## Vesicular Laterite

Mr. G. Ap Griffith's contribution to the long-debated problem of the origin of vesicular laterite is welcome[1].

I am well acquainted with laterite beds and pavements in Ceylon and eastern and southern Africa, and I am aware of no case in which organic agency need be considered in the production of this very distinctive deposit. An up-to-date study of the subject is provided by Prescott and Pendleton[2].

More than forty years ago I watched Africans in the Mozambique Territory using laterite pellets, washed out of river banks by ephemeral streams, as shot for muzzle-loaders.

One might here record that both mature and semi-formed laterite can be found in certain places beneath the Kalahari sand in Bechuanaland. Stone implements may be found lying upon it, or otherwise associated with it, and examples of artefacts with fragments of the ironstone adhering to their worked surfaces are not wanting. The laterite so found is pre-Kalahari sand in age, and thus provides striking evidence of the pre-desert climate.

I have no doubt that Mr. Ap Griffith's solution of this laterite problem is correct, so far as it goes. Laterite pellets and nodules can be seen in process of formation to-day; but in many places optimum conditions for the production of vesicular laterite no longer obtain.

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Entomologist in the Tsetse Fly Operations Branch, Department of Agriculture—The Secretary, Southern Rhodesia Government, Rhodesia House, 429 Strand, London, W.C.2 (June 20).

Laidon Foundation Fellowship in Organic Chemistry—The President, University College, Dublin (June 20).

Lecturer in Inorganic or Physical Chemistry, and a Lecturer in Civil Engineering—The Secretary, Queen's University, Belfast (June 20).

Lecturer in Microbiology (with special qualifications in microbiological chemistry or cell biochemistry, and have undertaken independent research in some branch of these subjects)—The Registrar, The University, Reading (June 20).

Lecturer in Psychology—The Secretary, The University, Aberdeen (June 20).

Senior Lecturer in Mathematics—The Registrar, College of Technology, Birmingham 1 (June 20).

Assistant Lecturer in Physics, and a Lecturer in Electrical Engineering—The Registrar, College of Technology, Manchester 1 (June 22).

Physicist (with honours degree in physics) for radio-isotope work in the University Department of Medical Physics—The Registrar, The University, Leeds 2 (June 22).

Psychologists in the Admiralty, Air Ministry, Civil Service Commission, and Prison Commission—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting 76/53 (June 25).

Assistant (temporary) in the Department of Agriculture (Animal Husbandry)—The Registrar, University College, Aberystwyth (June 26).

Hospital Biochemist (with degree in chemistry or A.R.I.C.), and a Research Assistant (biological) (with degree in physiology or zoology)—*The Professor of Chemical Pathology*, Westminster Medical School, 17 Horseferry Road, London, S.W.1 (June 26).

Assistant Lecturer in the Department of Agricultural Economics—The Registrar, University College of Wales, Aberystwyth (June 27).

Lecturer or Assistant Lecturer in Geography at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (June 27).

Physicist (with *first- or second-class* honours degree or equivalent in physics) in the Metallurgy Department, Royal Aircraft Establishment, Farnborough, for work on X-ray diffraction of solids and liquids—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting A.186/53A (June 27).

Research Assistant in the Department of Botany—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (June 27).

Assistant Experimental Officers in the Entomology an Weed Ecology Sections, and a Scientific Officer in the Irrigation Section—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (June 29).

Lecturer and an Assistant Lecturer in the Department o Leather Industries—The Registrar, The University, Leeds (June 29)

Assistant Agricultural Economist (with a degree in economics agricultural economics or agriculture) in the Eastern Province o the Provincial Agricultural Economics Service—The Secretary, Schoo of Agriculture, Downing Street, Cambridge (June 30).

Assistant Lecturer in Animal Physiology—The Secretary and Registrar, The University, Southampton (June 30).

Colville Fellowship in the Department of Chemistry—Th Professor of Chemistry, Royal Technical College, George Street Glasgow (June 30).

Graduate Students in Physics, Chemistry or Engineering for Research Scholarships (5) tenable at the Universities of Oxford Cambridge, London, Birmingham and Glasgow—The Secretary, Th Gas Council, 1 Grosvenor Place, London, S.W.1 (June 30).

Lecturer in Physiology, and a Demonstrator in Physiology—The Registrar, King's College, Newcastle-upon-Tyne (June 30).

Nuffield Research Studentships and Fellowships for experimental and theoretical research in nuclear and elementary particl physics—The Professor of Natural Philosophy, The University Glasgow, W.2 (June 30).

Senior Lecturer or Lecturer in Parasitology at the University of Malaya, Singapore—The Secretary, Inter-University Counci for Higher Education in the Colonies, 1 Gordon Square, London, W.C. (June 30).

Lecturer in Mining—The Registrar, King's College, Newcastle upon-Tyne (July 1).

Lecturer in Chemistry (with special qualifications in physica chemistry)—The Registrar, University College, Cathays Park, Cardi (July 4).

May and Baker Research Fellowship, for research on plan growth-regulating substances—The Registrar, Wye College, Wye Ashford, Kent (July 4).

Assistant in Experimental Physics—The Secretary, Th University, Aberdeen (July 8).

Senior Experimental Officer in the Ministry of Supply, Londo headquarters, for research and development of natural and syntheti aircraft textile materials in all forms, technical consultations wit industry and research organizations concerning selection of material manufacturing and user problems, and the preparation of specification —The Civil Service Commission, Scientific Branch, Trinidad House Old Burlington Street, London, W.1, quoting S.4216/53 (July 8).

Assistant in Statistical Research—The Secretary, Facult Board of Economics and Politics, The Marshall Library, The University, Downing Street, Cambridge (July 15).

Lecturer or Senior Lecturer in Philosophy at Canterbury University College, New Zealand—The Secretary, Association o Universities of the British Commonwealth, 5 Gordon Square, London W.C.1 (July 15).

Senior Research Awards for investigations on the followin aspects of locust physiology: (*a*) nutrition, with a view to developin a fully sufficient artificial diet, (*b*) vision and visual responses, (*c*) hea and/or water metabolism—The Director, Anti-Locust Research Centre c/o British Museum (Natural History), Cromwell Road, London, S.W. (September 1).

Plant Pathologist (with a wide knowledge of plant patholog in all its branches and, preferably, with tropical experience; an some aptitude for, and interest in, taxonomic work) in the Commonwealth Mycological Institute—The Secretary, Commonwealth Agricultural Bureaux, Farnham Royal, Bucks (September 15).

Assistant (Grade A) in Physics—The Principal, Technical College Queen Street South, Huddersfield.

Assistant Lecturer in Agricultural Chemistry (with specia qualifications in animal nutrition), and a Demonstrator in Agricultural Chemistry, in the Department of Agricultural Science School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

Biochemist or Clinical Biochemist interested in human biology to assist Dr. J. M. Tanner in investigation of metabolic and endocrinological differences in man, their genetical bases, and their development during childhood—Prof. H. Barcroft, Sherrington School o *Physiology, St. Thomas's Hospital, London*, S.E.1.

Chemist at a Ministry of Supply Research Establishment nea Sevenoaks, for inorganic analysis—The Ministry of Labour an National Service, Technical and Scientific Register (K), Almac House, 26 King Street, London, S.W.1, quoting F.228/53A.

Educational Psychologist (woman)—The Director of Educatio County Education Office, Castle Street, Worcester.

Investigator (with degree in metallurgy, physics, or engineerin or equivalent qualification) in the Department of Industria Metallurgy, *for research on elastic properties of spring materials*—The Registrar, The University, Birmingham 15.

Metallurgist (with first- or second-class honours degree or equivalent in metallurgy, and at least three years postgraduate researc experience) in the Ministry of Supply, London Headquarters—Th Ministry of Labour and National Service, Technical and Scientif Register (K), Almack House, 26 King Street, London, S.W.1, quotin F.245/53A.

Principal of Bhavsinhji Polytechnic Institute, Bhavnag (Bombay Region), *India*—The Ministry of Labour and Natio Service (A.S.12), Almack House, 26 King Street, London, S.W. quoting A.12/I.84B/53.

Scientific Assistant (with good knowledge of physics and rad maintenance) for service in the Antarctic with the Falkland Islan Dependencies Survey—The Crown Agents, 4 Millbank, London, S.W. quoting M3B/33763/TA.

Senior Geneticist (with good honours degree in botany or oth natural science, with some years experience of plant breeding a *genetics*) at the West African Institute for Oil Palm Researc —The Director of Recruitment, Colonial Office, Great Smith Stree London, S.W.1, quoting CDE.37/11/03.

# SCIENTIFIC INSTRUMENTS IN RESEARCH AND INDUSTRY

THE recent Exhibition of the Physical Society is still a lively memory and it will be followed by the second British Instrument Industries' Exhibition, which is to be held at Olympia, London, during June 30–July 11. These two Exhibitions, while necessarily having a considerable amount of common ground, have essentially different backgrounds, and it is the two Exhibitions in combination which furnish a complete picture of the functions of scientific instruments at the present time and of the revolutionary changes which have taken place in those functions during the past two or three decades. While some users of instruments may feel that their interests lie entirely in the Physical Society's Exhibition and while others may feel that the British Instrument Industries' Exhibition, with its more utilitarian atmosphere, is more likely to be of value to them, yet a better spirit of understanding between the users and manufacturers of instruments might well be fostered if visitors to the recent Physical Society's Exhibition were to complement their experience by visiting the Exhibition to be held at Olympia.

In the application of science to utilitarian purposes, the use of scientific instruments has always played a major part; and it is therefore not surprising that the technological developments which have taken place during recent years in almost every sphere of human activity and endeavour have been accompanied by very drastic changes in instrument design and by a very considerable expansion of the field of instrument use. The original purpose of the founders of the Physical Society's Exhibition was to give Fellows of the Physical Society, and others interested in physics, an opportunity of seeing the current impact on instrument design of established principles of physics and of advances in physical knowledge. At that time the scientists, for the benefit of whom the Exhibition was staged, were, in fact, the main users of scientific instruments. This main purpose of the Physical Society's Exhibition still provides the guiding principle governing its organization, and although the field of use of instruments has extended far beyond the confines of the scientific world, and although the main user of instruments is no longer the man of science, yet a demonstration of the impact of scientific knowledge on instrument design is still clearly to be discerned at the Physical Society's Exhibition. On the other hand, the main purpose of the British Instrument Industries' Exhibition is to indicate the impact which the use of scientific instruments can make on the carrying out of industrial processes, on the precision of engineering and, in fact, on every department of life on which the hand of technology has been firmly placed in this present age. In other words, the Physical Society's Exhibition still, to some extent, reflects the old scientific use of instruments: the Exhibition to be held at Olympia reflects the new use of instruments, which is now far more widespread than the old.

A survey of the whole field of instrument manufacture would reveal that the accurate measurement of physical quantities is no longer the sole function of a very large proportion of instruments, although they may well be capable of making such measurements. The main function of these instruments is to utilize this property of precise measurement for some ulterior purpose; an example coming immediately to the mind is the continuous recording or control of temperature. With the conversion of instruments from measuring devices to controlling mechanisms, the border-line between instrument making and engineering has become very obscure. It is, however, still true that the most fruitful source of ideas which may eventually be incorporated in some new form of instrument is the science research laboratory; and one of the difficult problems of instrument manufacture to-day is to provide investigators in the various fields of science with the particular and peculiar instruments required by them, while at the same time meeting the demands imposed by the adoption of the scientific instrument as a major tool in industry.

It should be remarked that the research worker has himself reaped considerable advantage from the great demand which exists for instruments in the new fields of use. The character of academic research laboratories has been subject to changes no less striking than those which have occurred in the instrument and technological spheres. The urgency of research and the increased complication of the apparatus used in research have combined to limit the possibility of relying, for the building of research gear, mainly on internal mechanical resources and the skill of the researcher's hands. One characteristic of modern research laboratories is the great use made of commercial scientific instruments, and it is largely true that it is the demand for instruments from outside the scientific world which has given to the instrument industry the resources for the creation of development and research facilities, without which the almost bewildering variety of types of instruments, capable of use in so many directions, would never have been produced. To that extent the research worker has gained by the changes which have occurred in the use of instruments; but, nevertheless, the clamant demand for instruments outside the laboratory makes it difficult to produce the instruments, often of a very special character, required inside the laboratory, and presents to the instrument manufacturer a problem to which a completely satisfactory solution is difficult to find.

From the commercial point of view, it is probable that the demand of the science research worker for instruments is of less importance than the demand for instruments from utilitarian sources. Since, however, the basic raw material of scientific manufacture is scientific knowledge, it is of the highest strategic importance that the research worker should not be handicapped by having to use instruments not specially relevant to his purposes. It should be remarked that the effort given within the industry to the making of what are known as 'research instruments' is very considerable; but the problem of supplying on an economic basis instruments o very special character for which the demand can, the nature of the instrument, only be very small, a very real one and demands that the maximu degree of adaptability and flexibility should be fou both in the user and in the manufacturer. To t end a common knowledge of the problems of bo user and producer cannot but be helpful, and c tainly the British Instrument Industries' Exhibitic taken in conjunction with the Physical Societ Exhibition, should give the man of science an insig into the breadth of the commitments of the instrume industry.

# TRIALS AND TRIBULATIONS OF CYTOCHEMISTRY

## Cytochemistry

A Critical Approach. By Prof. J. F. Danielli. (Wil
Biological Research Series.) Pp. ix+139+12 plate
(New York: John Wiley and Sons, Inc.; Londo
Chapman and Hall, Ltd., 1953.) 32s. net.

CYTOCHEMISTRY, even enzyme cytochemistr is not as recent a development as many peop seem to imagine; Nadi oxidase and Dopa oxida reactions demonstrate that. The specific chemic delineation of cellular constituents is, in fact, mo than a hundred years old, and before the developme of aniline dyes investigations of this type were bei actively pursued. The introduction of a vast ne series of dyestuffs and the ease with which they ma possible the delineation of structure led to a co centration on cell morphology and the introductic of a spurious chemical nomenclature for cell co stituents, and the older work was discontinued. I the past thirty years, however, the development new techniques, new apparatus, new chemicals a new ideas has led to a rebirth and intensification cytochemical research. At the beginning of th Second World War the development by Gomori a by Takamatsu of a new technique for histo- and cyt chemical localization of phosphorolytic enzymes le to an amazing burst of interest in, and work c phosphatase, and resulted in a spate of publicatio on this subject. It was fatally easy to obtain resul with a technique like that for alkaline phosphatas and it became obvious that some of the publishe work had been carried out by those who thought the phosphatase reaction simply as just anoth cytological staining technique without appreciati the chemistry and physics of what they were doing.

In the past few years a number of workers ha sought to remedy this fact and in some cases th themselves have reacted too far in the opposi direction and brought the phosphatase technique in a state of undeservedly ill repute. So far has th gone that statements have even been made that th phosphatase technique gives no indication at all the intra-cellular distribution of the enzyme.

The time was obviously ripe for a careful a detailed consideration of this and other histochemic techniques, and the appearance of a work of th nature by J. F. Danielli is timely. His work divided principally into four main studies: alkaline phosphatase, on aldehydes, on proteins, a on nucleic acids. These studies are prefaced by introductory chapter and by one on fixation, a they are followed by a consideration of quantitative cytochemistry and a forecast of the cytochemical future.

There is no doubt that Prof. Danielli has produced a critical and balanced account which is of great value. The work in general is free of bias and all points of view are given fair treatment and comment. However, it is not surprising if the reviewer does not agree wholeheartedly with the statement on p. 2 that "A good training in histology is one of the worst backgrounds possible for cytochemical work". The same comment would apply with equal force to many other specialities, and many of the cytological contributions of biochemists make it quite obvious that a thorough study of Wilson's "The Cell in Development and Heredity" should be compulsory for them as well as for histologists, and also for others who seek to embark lightly and untrained on a voyage into a region which is fraught with the most peculiar dangers and bristles with traps for the uninitiated and the unwary. It seems likely, however, that Prof. Danielli, in making his statement, is really referring to those who think that "anyone who can cut a tissue section and make up a standard solution is competent to carry out cytochemical investigations", and if this is the case the reviewer would agree with him. He also utters a particular word of warning against the too facile acceptance of the results of differential centrifugation of cell homogenates, and although recent cytochemical results have supported some of this work such a warning at this stage is highly desirable. The discussion on the phosphatase reaction is comprehensive and critical, but the section on aldehydes, although valuable, could have been expanded with advantage. There is also, for the first time to the reviewer's knowledge, a useful evaluation of Caspersson's work—apart, of course, from those which deal with it from an optical point of view. Prof. Danielli's explanation of the significance of phosphatase for cell penetration in which he postulates that phosphatase acts as an enzymic centre of a contractile protein is most ingenious, and one looks forward to further experimental support or this idea.

From the date of the preface and from the dates of the references it is obvious that the manuscript of his work has spent an unusually long time in the press, which is a pity. Nevertheless, Prof. Danielli has produced a readable, critical work on a subject which badly needed a critical approach, and no person arrying on histo- or cyto-chemical investigation hould fail to read it. Geoffrey H. Bourne

## DESCARTES

**The Scientific Work of René Descartes (1596–1650)**

By Dr. J. F. Scott. Pp. x+211. (London: Taylor and Francis, Ltd., 1952.) 21s. net.

DESCARTES, like his contemporary Pascal, enjoys a great dual reputation, though only a few of those who study his work are aware that he has the right to more than one. An enigmatic personality, because much of his life-story is obscure, his character is rendered even more puzzling by what we know of it. Paradoxically, the man who, in the Discours de la Méthode" and its accompanying treatises on physics, geometry and algebra, gave to the world a synthesis of scientific principles and a isplay of their application comparable to the great medieval compilations, was in temper and outlook far removed from both the equably minded philosopher and the modern scientist. It is perhaps understandable that he should have avoided controversy and defended his priority by making "La Géométrie" too difficult for most of his contemporaries to comprehend—a method superior to Newton's, which consisted in merely withholding publication; but it is curious, to say the least, that he could find no merit in Galileo, Fermat or Pascal, and that he invariably denied all credit to his predecessors, even when his indebtedness to them was obvious and considerable.

However, what is more relevant to an estimate of Descartes's scientific contributions is the specific point of view of their author. By the time that Descartes was composing his first great work, Renaissance thought had made its mark upon mathematics; fundamental advances in algebra were nearly a century old, and Galileo had already formulated his ideas on dynamics. Yet although Descartes may justly be described as one of the founders of modern mathematics, he is more strikingly a child of the past, and especially of the Schoolmen. Thus, while he sought for mechanical explanations of natural phenomena—and in the field of optics actually found them—his scientific procedure was rational chiefly in Whitehead's sense of the word; according to Descartes (and also to some of our contemporaries) the function of experiment is not to provide a basis for theoretical superstructure, but to confirm notions already conceived *a priori*. It can only have been by this route that Descartes arrived at his theory of vortices, which at once became enormously popular as an all-embracing explanation of the universe, and for more than a century resisted all attempts to dislodge it: as late as 1730, no less a person than Jean Bernoulli published an essay denouncing Newton's theory in its favour.

Such misjudgments in a realm where, as the history of astronomy seems to show, one man's guess is almost as good as another's, are, however, to be found in other branches of Descartes's work. Thus his treatise on analytical geometry, which initiated the modern approach to the subject, only partially aimed at reducing geometrical problems to algebraic form: Descartes was equally concerned to reverse the process, in the true spirit of the Greeks. Again, his solution of the problem of drawing a tangent to a curve—one of the foremost questions of the day—began by constructing the normal. His companion treatise on algebra, which effected great improvements in notation, suggests at the same time that the author himself was scarcely ready for all of them: although he employed literal coefficients and enunciated the rule of signs for algebraic equations, it is evident that he was even less happy with negative numbers than were some of his forerunners.

All things considered, it seems fair to say that Descartes's work has achieved importance despite the obscurantism, intentional or otherwise, of its expositor. The present account of it by Dr. J. F. Scott, who is already known for his interesting book on John Wallis, treats the subject sympathetically while not attempting any unjustifiable defence. It begins with a sketch of Descartes's life and a general survey of his work, and then proceeds to analyse each of the treatises in detail. These cover such a wide range that there is something for every scientific taste; mathematicians, in particular, will be fascinated by the descriptions of Descartes's methods in geometry and algebra, which include a welcome account of the problem of the *locus ad quatuor lineas*, from which, it is believed, co-ordinate geometry was born.

The book is copiously illustrated; and the author has had the happy idea of including brief biographies of all the minor personalities mentioned in the text. Printing and binding are excellent. L. ROTH

# CRYSTALLOGRAPHICAL STRUCTURE REPORTS FOR 1949

Structure Reports for 1949

Vol. 12. General Editor: A. J. C. Wilson. (Published for the International Union of Crystallography.) Pp. viii+478. (Utrecht: A. Oosthoek's Uitgevers Mij., 1952.) 45 Dutch florins.

THE format of Vol. 11—as the prototype of the new series of "Structure Reports" published by the International Union of Crystallography—excited almost as much interest at the time of its publication as the structural data it contained, for with it there reappeared a valuable series of reference works upon which one may confidently rely.

With the appearance of Vol. 12, one can turn directly to the contents, since it was prepared by the same editors more-or-less concurrently with Vol. 11 and is strictly isomorphous with it, being strongly bound, well printed, adequately illustrated and extremely comprehensive; the arrangement within individual reports is, as before, name, formula, papers reported, unit cell, space group, atomic positions and parameters, interatomic and intermolecular distances, material, discussion, details of analysis and references. Happily the editors have been entirely successful in providing this wealth of detail without that sacrifice of clarity which makes the extraction of information from some reference books almost a kind of parlour game.

It is a striking indication of the potentialities of structural crystallography that the work reported in this volume represents the output of but a single year—a prodigious quantity even after allowance has been made for the publication of work carried on during the War, such as the investigation of penicillin and of many of the compounds of the trans-uranium elements. Current trends are everywhere discernible; for example, in the organic section, there are reports on the increasingly accurate determinations of the structure of aromatic hydrocarbons now available for comparison with quantum mechanical calculations, while in the inorganic section are some of the first-fruits of the neutron diffraction experiments, such as the structure of $UH_3$—a most unpromising substance for a crystallographer equipped only with X-rays. There are also reports of structure determination from single-crystal electron diffraction patterns.

One striking thing is the steady increase of symmetry from the frequently monoclinic or even triclinic crystals of organic compounds through the mainly orthogonal lattices of the inorganic section to the predominantly cubic structures of the metals section. This high symmetry is a valuable asset when one realizes how much of the work on alloys is done with powders. Occasional references to as yet unindexed patterns of high complexity remind us that a really satisfactory generalized solution of powder patterns of any symmetry is still required, in spite of some recent advances. As regards technique, however, one wonders whether the statement on p. 231, that "Absences, observed on Laue and oscillation photographs, show the above space group" ($P2_12_12_1$), indicates an unusually ingenious experimenter, or merely a tired abstractor.

The fullness of these structure reports makes the volumes particularly useful for rapid surveys of special topics in which one is currently interested—such as carbon–sulphur bond-lengths, or the frequency of polymorphism among organic crystals. Since useful ideas can be quickly substantiated in this way, and unprofitable speculations as rapidly deflated, such books are a constant challenge to review the data from some novel point of view, and thus a powerful stimulus to us all to avail ourselves of the rich diversity of experimental material now available as a starting-point for new adventures into the unknown. H. J. GRENVILLE-WELLS

# STRUCTURAL LINGUISTICS

Methods in Structural Linguistics

By Zellig S. Harris. Pp. xv+384. (Chicago: University of Chicago Press; London: Cambridge University Press, 1951.) 56s. 6d. net.

THE basic concept of structural linguistics is substitutability, and the nature of the subject may be explained by the two following examples. First, in the English word ***kingcup***, the two [k]-sounds are well known to be different (I write $k_1ingk_2up$); if, now, the philologist, interchanging them, says $k_2ingk_1up$ to a native English speaker, he is told that the interchange is immaterial; if, however, he substitutes the initial sound of ***man*** for $k_1$, producing $mingk_2up$, he is told that the interchange is not immaterial (for a ***Ming cup*** is not a ***kingcup***). By this procedure the philologist has learnt that there is an essential difference between the distinction $k_1/k_2$ and the distinction $k_1/m$; he therefore makes one 'phoneme' [k], materializing in at least two forms $k_1$ and $k_2$, and another, different phoneme [m]. Secondly, the informant will allow the substitution of *from* for *to* and will not allow that of *dog* for *to* in the phoneme-block *Come to London*; in this way the philologist learns that *to* and *from* are 'morphemes' of the same kind and that *dog* is a different kind of morpheme from *to*.

Prof. Z. S. Harris's long and complicated book is essentially devoted to the problems indicated by the above two examples. He describes how the phonemes and morphemes of a language may be set up by the sole aid of a native informant (as an example of the first procedure, he sets up the phonemes of Swahili). His account of the concepts and methods is entirely lucid; regrettably, the book lacks an index of authors cited—were such an index made, many philologists might feel that it contained an undue proportion of American names.

Structural linguistics appears, rather refreshingly, to have little theory underlying it; it is a purely practical discipline, and it therefore stands or falls solely according to whether it does or does not accomplish what it purports to—that is, to extract the phonemes and morphemes of a hitherto unstudied language. With regard to phonemes, the 'cross-word puzzle' method which Mr. J. Josephs and I advocate is undoubtedly greatly superior to the structural linguistic method, but our method suffers from the grave disadvantage that it can only be applied to languages which possess at least one speaker who appreciates, or who can be trained to appreciate, the nature of the concept 'phoneme'; of the world's languages, approximately ten thousand in number, perhaps not more than five hundred possess such a speaker. The structural-linguistic method depends entirely upon getting the 'right' response to a substitution from a native informant; presumably, the latter can make three different responses: 'immaterial' (*$k_2$ingk$_1$up* for *$k_1$ingk$_2$up*); 'not permissible' (*hingk$_2$up* for *$k_1$ingk$_2$up*)—[k] and [h] are different phonemes in English; and, 'it alters the meaning' (*Ming cup* for *kingcup*). Can we really be sure that native informants will always distinguish clearly between these three responses? The structural-linguistic method *could* be tested against the cross-word puzzle method (though, so far as I know, it has not yet been); Lappish, with its highly complex phoneme-system, would be an excellent language for the test; we could use the structural-linguistic method on a 'primitive' kind of Lapp and see if the results agreed with those obtained, on the cross-word puzzle method, by a Lapp of, say, Ph.D. standard (at least one such exists).

# FLORA AND VEGETATION OF IRELAND

Die Pflanzenwelt Irlands (The Flora and Vegetation of Ireland)

Ergebnisse der 9 Internationalen Pflanzengeographischen Exkursion durch Irland 1949. Redigiert von Werner Lüdi. (Veröffentlichungen des Geobotanischen Institutes Rübel in Zürich, Heft 25.) Pp. 421. (Bern: Hans Huber, 1952.) 26.50 francs.

THE International Phytogeographical Excursion of 1949, held in Ireland under the leadership of Prof. D. A. Webb and Mr. G. F. Mitchell, was attended by twenty-three botanists of some twelve different nationalities, and was the ninth of a series of meetings of specialists in plant ecology which have done much to promote international understanding in a field where opinions tend more than usually to differ.

The present volume begins with a narrative of the Excursion and a report on the "Second Conference of Pollen Workers" which took place afterwards in Dublin; these are followed by short but authoritative accounts of Irish geology and the Irish flora, by Mr. Mitchell and Prof. Webb respectively, then by ten original contributions by K. Jessen, Max Welten, J. Heslop-Harrison, I. Markgraf-Dannenberg, F. Markgraf, H. Gams, F. Firbas, J. Braun-Blanquet, R. Tüxen and W. Lüdi (who edited the whole volume).

Among the topics dealt with are the pollen analysis of Irish peat, Irish dactyloid orchids, oceanic bryophytes and Irish woodlands. In an interesting account of Irish *Festuca* races, I. Markgraf-Dannenberg records an interesting addition to Ireland's Mediterranean flora, *F. ovina* ssp. *indigesta* (Boiss.) Hack., previously known only from the French Pyrenees and the Iberian Peninsula. In another paper Dr. Braun-Blanquet refers to a distinct race of *Antennaria dioica* found on the Irish eskers, which he has described elsewhere as *A. hibernica*.

Dr. Lüdi has some interesting comments to make on the different habitats, in Switzerland and Ireland respectively, of *Empetrum nigrum*, *Calluna*, *Sedum roseum* and other plants. In an article mainly concerned with the well-known problem of the occurrence of the usually basiphilous *Schoenus nigricans* in ombrogenous Irish bogs, Prof. Firbas refers to the view, originally proposed by Nilsson-Ehle, that the xeromorphy of bog plants is related to mineral starvation rather than to water shortage.

The history of the Irish flora is a constantly recurring theme in many of the contributions. Dr. Jessen, in a paper summarizing his own researches on the late Quaternary deposits, points out that in Zone III of the Late Glacial, Ireland was to the north of the polar timber line; nevertheless he thinks it possible that the American and most of the Lusitanian species (except woodland plants such as *Arbutus*) may have been able to survive the last glaciation in favourable places, an opinion with which several other contributors seem to agree.

By far the longest chapter in the book is the description by Dr. Braun-Blanquet and Dr. Tüxen of the plant communities met with during the Excursion. Since a very representative fraction of Ireland was traversed, almost every plant community above the tide-mark is dealt with. This contribution will be greatly appreciated by British ecologists, since communities with which they are familiar (those of Ireland being in the main similar to those of Great Britain) are classified here according to Dr. Braun-Blanquet's well-known system; thus for the first time we have an excellent basis for forming an opinion on its much-debated merits. It is impossible to discuss this question here, but it is perhaps worth directing attention to the extreme artificiality of a scheme which names one of its major divisions ('*Potentilletalia caulescentis*') after a species which does not occur within some seven hundred miles of Ireland, and divides into several widely separated categories the communities which are normally found successionally connected and spatially contiguous on sand-dunes. On the other hand, it must be freely admitted that Dr. Braun-Blanquet's clear and methodical procedure represents something still missing in British ecology. May we hope that a method of classifying vegetation may yet be developed which will retain this desirable feature without the artificiality?

British ecology has been insular for too long, and in Britain we have much to gain by realizing that our plant communities are for the most part impoverished versions of those better and more extensively developed on the Continent. It is as a help towards this end that this report of the Excursion is valuable, and we may be particularly grateful for the comparisons with France, Spain and other countries which the unrivalled experience of Dr. Braun-Blanquet and Dr. Tüxen enables them to make. Naturally, the hurried impressions of three weeks are not always accurate: several contributors stress as peculiarly Irish features which are equally well displayed in western Scotland and Wales—for example, it is not only in Ireland that the two species of *Hymenophyllum* grow together. Nevertheless, the British ecologist will be grateful to the contributors to this volume, for helping him to see his own vegetation as others see it.

P. W. RICHARDS

# THE ROYAL BOTANIC GARDENS, KEW

## CENTENARY OF THE HERBARIUM AND LIBRARY

THE modern history of Kew began in 1841 when the Royal Gardens became a government institution and William Jackson Hooker, professor of botany in the University of Glasgow, was appointed director. There was then neither herbarium nor library at Kew and the new director brought with him his own collections and books. In 1853 Miss E. Bromfield presented to Kew the Herbarium and Library of her late brother, Dr. W. Arnold Bromfield, and these formed the nucleus of the present Herbarium and Library. In 1854 George Bentham gave his valuable collections to be added to the Bromfield Herbarium and Library, and in 1866 the Government purchased the private collections of Sir W. J. Hooker. The Bentham and Hooker Herbaria, together with new collections that quickly began to be sent to Kew, led to the rapid growth in size and importance of the preserved botanical collections and the essential library. To these early donors or collectors Kew owes a double debt: the richness of the Herbarium in early types and the complete runs of many valuable periodicals in the Library. In addition, the Hookers and Bentham, by the excellence and number of their published researches, made Kew the world centre of botanical, and especially of botanical systematic, studies. The Herbarium now contains some six million 'specimens' and the Library more than fifty thousand volumes.

Since it was in 1853 that the Bromfield collections were presented, it is appropriate that the centenary of the Herbarium and Library at Kew should be celebrated in 1953. To mark the occasion an exhibition of specimens, books, manuscripts, diagrams, photographs, drawings, etc., was arranged in the three wings of the Herbarium and in the Library. Official guests, individual scientists, university students, and members of many scientific societies visited the exhibition during the period May 7–9. The theme of the exhibition was the research carried out at Kew during the past hundred years, and particularly that in connexion with the systematics of plants. About fifty separate but interconnected series of exhibits, some of them extensive, were staged by members of the staff, who ably demonstrated their special subjects.

The early period of Kew, and of the Herbarium and Library in particular, was illustrated by photographs, plans, drawings, and original items of historical interest. The unbroken sequence of administration could be followed through the periods of directors from Sir W. J. Hooker to the present director, Sir E. J. Salisbury, and of keepers from Prof. Daniel Oliver to the present keeper, Dr. W. B. Turrill. It was clearly shown that, in addition to carrying the burden of administration, now greatly increased, both the directors and keepers contributed considerably to botanical knowledge by their own researches.

The work of the Herbarium is divided into departments on a double basis, purely systematic and phytogeographical. The systematic divisions were well illustrated by the work done at Kew on the cryptogams. Collections of Algæ dating from the voyages of H.M.S. *Erebus and Terror* and of H.M.S. *Challenger* were on view as well as those used by well-known algologists. The taxonomy of fungi has received much attention at Kew during the past century, and the collections and work of Cooke, Massee, Wakefield, and others attract many mycologists to study, often for long periods, in the Herbarium. Selections from types of W. J. Hooker to recent additions illustrated the rich material of liverworts and mosses preserved in the Herbarium and now being revised. The pioneer investigations of W. J. Hooker and J. G. Baker on the ferns and fern allies greatly enriched Kew in type specimens. Examples of their materials and the results of their researches were contrasted with a fine collection of living plants of twenty-six genera of ferns recently gathered in Ceylon and now being grown at Kew. This was only one of many exhibits showing the facilities existing, and utilized, at Kew for linking together the study of living plants with the examination and comparison of numerous preserved specimens of diverse origins.

There are at Kew specialists for the orchids and grasses, but most of the work carried out on the seed-bearing plants is divided on a geographical basis. Monographic studies have not been neglected; but, partly because of the need for development of what are now Dominions, Colonies, or Protectorates, a major item in the policy at Kew has been, and still is, to prepare Floras of areas usually with political boundaries. These sometimes coincide closely with phytogeographical divisions, but are sometimes more or less artificial. The practical advantages of having accounts complete to date of publication, with descriptions, keys to determination of taxa, summaries of known range and distribution, etc., for this or that portion of the Commonwealth, needs no emphasis. Their preparation should naturally be a British enterprise and, moreover, involves no competition with either the preparation of floras for other parts of the earth's surface or with that of systematic monographs such as those of the "Pflanzenreich".

In preparing the centenary exhibition, members of the staff had a wealth of material from which to select subjects to illustrate the contributions of their predecessors and themselves to floristic research. A tabulation based on a map of the world listed forty-one Floras prepared entirely or largely at Kew. These ranged from single volumes, as those of Bentham and Hooker "Handbook of the British Flora", or the 'Flora Simlensis", to the many volumes of the 'Flora of British India" or the "Flora of Tropical Africa". A complete survey of the floristic and phytogeographical interests of past and present members of the Kew staff, and of other botanists who have carried out much of their work at Kew, would occupy much space, and here only a brief account of some of the collections and of work published as a result of investigations conducted at or in connexion with Kew can be given. Since the time of Bentham and Hooker, many members of the Herbarium staff have carried out field studies on the British flora as a recreation, mainly concentrating on a few special families such as those of the orchids, sedges, and grasses or detailed investigations of smaller groups. The Herbarium, in fact, contains valuable special collections of British plants such as those of Bromfield, Lightfoot, Borrer, and Watson. It happens that three or four species new to the British flora have quite recently been first recorded from material sent or brought to Kew. Specimens of these were exhibited. The flora of Europe and the Orient (Nearer East) is well represented in the collections, and researches, especially on the plant life of the Balkan Peninsula and Cyprus, have been published in book form and in series of papers. The rich harvest of plants from China garnered by Henry, Wilson and other famous collectors must be consulted by students of plants of the Far East, and its importance is enhanced by the many species introduced into horticulture. The "Index Florae Sinensis" is based almost entirely on material at Kew. The service of J. D. Hooker to our knowledge of Indian plants must always be acknowledged since it culminated in the classic "Flora of British India". This was followed by the publication of a series of more local floras, many of which were prepared at Kew. The plants of Siam were largely worked out by a former member of the Kew staff, and the "Flora of the Malay Peninsula" is indissolubly linked with Kew.

The greater part of the continent of Africa has been covered botanically by Kew publications, including the "Flora of Tropical Africa", the "Flora Capensis", the "Flora of West Tropical Africa" (now under revision), Hooker and Ball's work on Morocco, and numerous other books and papers. Publication of the "Flora of Tropical East Africa" has recently begun. Exhibits connected with these and other floristic researches consisted of dried specimens, living plants (many illustrating special morphological features or peculiar physiological behaviour), statistical tables, drawings and paintings, methods of collecting, and of printed books and papers.

Bentham's "Flora Australiensis" and J. D. Hooker's Floras of the southern hemisphere together form the foundation of all subsequent studies of the flora of Australasia. Much of the later floristic research has been carried out by Australian and New Zealand botanists at their own institutions; but Kew has always maintained the happiest relations with them and a great interest in their work, and they continually add new specimens to the extensive representation. Samples of the collections recently made in the Montebello Islands were exhibited.

Apart from early researches on the floras of temperate North America and Central America, relatively less work has been done at Kew on American botany than on the plants of other continents. Exceptions to this generalization are the continued investigations concerning the botany of Trinidad and Tobago and British Guiana.

Mention must be made of Kew's contribution to the general classification of flowering plants as exemplified in the "Genera Plantarum", the "Index Kewensis", the new arrangement in "Families of Flowering Plants", and the contribution of members of the staff to the modern International Rules of Plant Nomenclature. Exhibits connected with these were varied and instructive.

The Kew collection of drawings, paintings, and photographs of plants is the most comprehensive in the world. Fine series illustrative of the work of both Kew artists and of that of others from the fifteenth century to the present day formed a notable feature of the exhibition. Other special exhibits illustrated researches (including cytological) in connexion with the National Dianthus Collection, the methods of preserving plant materials, the organization of herbarium work, the use and preparation of Floras, plant teratology, researches on the genus *Utricularia* and on *Bromus carinatus*, the use of genetics in taxonomy, and the introduction of plants to horticulture.

The researches carried out by the Herbarium staff at Kew are mainly taxonomic in the widest sense of this term. Modern taxonomy includes more than describing and naming dried specimens. The close co-operation of the Herbarium staff with that of other departments of the Royal Botanic Gardens, Kew, was evident in the numerous well-chosen examples of living plants from all parts of the earth and all connected with researches carried out by past or present scientists at Kew. Again, the importance to taxonomists of anatomical and physiological characters was emphasized by a large exhibit of apparatus, slides, and accounts of experiments staged from and illustrative of the work of the Jodrell Laboratory. Though the work at Kew is primarily scientific research, problems of immediate economic importance are often closely linked with and sometimes lead to special investigations. Samples of such connected with timber, fibre-, perfume- and oil-producing plants, species yielding drugs, and crops of various kinds were on view with the published results.

In the Library, visitors were able to see many of the valuable books from the libraries of Bromfield, Bentham, and W. J. Hooker, as well as others more recently acquired. Old herbals, manuscripts, diaries, and original drawings were also on view. Books purchased by the Bentham–Moxon trustees add greatly to the usefulness of the Library. A special exhibit showed some of the books written by members of the Kew staff and of the periodicals prepared at and, in part, published by Kew: the *Kew Bulletin*, *Icones Plantarum*, "Index Kewensis", and (edited at Kew for the Royal Horticultural Society) the *Botanical Magazine* and the "Index Londinensis".

# SIZE AND SHAPE OF MACROMOLECULES*

By Prof. H. W. MELVILLE, F.R.S.

**Chemistry Department, University of Birmingham**

POLYMER molecules of natural or synthetic origin can be generally classified as linear, branched or cross-linked. Sometimes these molecules are referred to as one-, two- or three-dimensional, respectively, the reason being that a linear molecule may be varied in length over a very considerable range, from a matter of a few angstroms up to as much as nearly a hundred thousand. Similarly, a two-dimensional molecule if placed on a plane surface may be extended in two directions up to the same kinds of limit. Correspondingly, a three-dimensional molecule may extend, without limit, in three dimensions. In this last-named case it is true to say that any isolated piece of polymer may represent one giant molecule, though in many actual cases there may be embedded in the three-dimensional array of atoms linear and branched-chain molecules, produced as a result of the synthetic process.

Progress in determining the size, shape and structure of these types has been very uneven, and this account is confined to a discussion of the problems that arise in dealing with molecules of synthetic origin only. Generally speaking, there are innumerable ways of building up linear molecules, the linearity of structure being assured by the chemistry of the synthetic process. It is equally easy to build up three-dimensional structures either by cross-linking linear molecules by suitable chemical methods, as in the vulcanization of rubber, or by choosing starting materials that would ensure the formation of three-dimensional molecules right from the beginning. The progress of synthesizing and characterizing the intermediate type of two-dimensional molecules proves to be very much more difficult, and little information is yet available about such substances. One-dimensional molecules are soluble in solvents, and hence it is possible to determine size, shape and often detailed structure comparatively easily. Three-dimensional molecules do not dissolve; at the most they only swell in suitable solvents, and hence the methods available for their study are very limited.

---

* Substance of a Friday Evening Discourse given at the Royal Institution on March 20.

Linear molecules range in molecular weight from a few hundreds up to about ten million. In the low range, molecular weight can be measured by the classical methods of lowering of vapour pressure, though specially sensitive instruments are needed to measure the very small lowering of vapour pressure if, for example, the molecular weight rises to values of above twenty thousand. Small elevations of the boiling point can be measured by multiple-junction thermocouples to $10^{-4}$ deg. C., and even vapour-pressure thermometers under very closely controlled conditions can achieve a similar accuracy, so that molecular weights up to thirty thousand may be measured with an accuracy of about 5 per cent.

Beyond this the osmotic method is easily applicable. The problem here to be solved is that of obtaining suitable semi-permeable diaphragms. Cellulose prepared in a variety of ways in order to obtain a sufficiently porous structure is the most satisfactory method; but the procedures used for its preparation are empirical, and thus there is no means of controlling the production of such membranes except by trying in an actual osmometer. While considerable control of porosity can be achieved, the determination of molecular weights less than about twenty thousand is a very difficult and protracted matter. Recently, polyvinyl alcohol has been used with great advantage; its porosity to polymer can be made so low that molecular weights even down to a thousand may be measured. At the upper end of the scale of molecular weights, the problems are rather different. The osmotic pressure may only amount to a few millimetres of benzene when the polymer has a molecular weight of a million in a solution of less than 1 per cent by weight. The deviation of such solutions from ideal behaviour is so great that it is essential to extrapolate results to very low dilutions in order that molecular weights can be calculated. Since good cathetometers can read to about $10^{-2}$ mm., it is therefore practically impossible to measure molecular weights exceeding one million. In order to measure osmotic pressures of, say, $10^{-1}$ mm. a new kind of principle is used in which the weight of solvent that enters an osmotic cell is weighed directly in an instrument called an osmotic balance. By suitable arrangement of the geometry of the system and by using photoelectric means of detecting the movement of the beam of the balance, molecular weights of ten millions can be measured in a rather slow way because the ten million limit comes within the limits of practicability at the expense of slowness of operation.

Fortunately, there are other methods which operate satisfactorily in the higher ranges of molecular weights. The most direct method involves counting by the electron microscope the number of molecules in a given weight of polymer. With a resolving power of 50 A. it should be possible to 'see' molecules with a weight of a hundred thousand and more. The difficulties in doing such a direct experiment are quite formidable. To deposit on the sub-stage from a very dilute solution as little as, say, $10^{-16}$ gm. of material in the form of individual molecules free from dust is a problem easily stated but much less easily done. There is therefore much to be done along these lines before the method can become accurate. Similarly, the ultracentrifuge, while so useful with monodisperse biological macromolecules, is much more difficult to use with synthetic polydisperse material, especially when such polymers assume an elongated shape in solution.

Two less direct but more useful methods have more recently been developed. The first makes use of the optical turbidity exhibited by polymer solutions, which is the greater the larger the size of the dissolved molecule for a given weight concentration. The development of the photomultiplier photoelectric cell has made it possible to measure accurately such small turbidities; but since the turbidity of pure liquids is quite comparable with that of the solutions themselves, the method is not very suitable when the molecular weight falls below fifty thousand. At the upper end of the scale, that is, about a million, when the length of the molecules in solution is comparable to the wave-length of light, the marked dissymmetry of the scattered radiation makes it essential to measure the intensity of forward scattering as near the incident beam as possible. This makes for considerable experimental difficulties, though molecular weights up to about one million are readily measurable. Since scattering is proportional both to the number and weight of the polymer molecules, the molecular weights so obtained are a so-called weight average as contrasted with a number average found by osmometry. The ratio of weight to number average gives an indication of the polydispersity of a sample, the weight average always being the greater. If a sample were monodisperse, the ratio of weight to number average should be unity. However the lowest published values amount to about 1· even with the most carefully fractionated material and therefore it may be confidently stated that rea fractionation of polydisperse synthetic polymers ha not yet been achieved in spite of many statement which might lead one to suppose that such fractionation had been satisfactorily done. The other method now being explored, makes use of the accurat estimation of end-groups in which one or more of th atoms is made radioactive. Some knowledge of th mechanism of synthesis is required—for example whether there are one or two terminal groups of th required type in each molecule. By using initiato molecules of quite moderate radioactivity, such a azo compounds, molecular weights up to a millio may be determined with very considerable accurac and using as little as 10 mgm. of polymer.

Thus methods exist to cover the range of molecula weights required, and the only remaining difficult is that some linear polymers—for example, poly ethylene, polyvinylidene chloride—only dissolve in solvents at elevated temperatures such as 100° C., and some polymers, such as polytetrafluorethylene, not at all. The upper limit in the range is not likely to be extended, for there seems to be a practical limit to molecular weights up to about ten million. This applies only to polyvinyl polymers. The main reason for this among those vinyl polymers which grow by radical mechanism is due to the phenomenon of transfer. A polymer radical during its growth may react with its environment, abstracting from it an atom and thus terminating the growth of that particular radical. Such a reaction, even at low temperatures, will therefore put a very definite limit on molecular weight. If synthesis could be conducted at very much lower temperatures, some increase in molecular weight might be possible. Even if this could be done, solutions of such high molecular weight are very easily broken down by relatively low rates of shear if subjected to movement, and thus the handling of such polymer solutions is subject to very considerable difficulty.

The process of transfer referred to above has another important consequence. When polymer accumulates in the system, there is a possibility that a polymer radical will attack a polymer molecule. The result is that the polymer molecule is converted into a radical, and this radical grows in an environment of the monomer, producing a branched-chain molecule. The reaction is specially likely to occur if the polymer radical is reactive, and therefore branched-chain molecules are likely to appear towards the end of the polymerization process. While such a process has been suspected for a long time, definite proof has only recently been obtained. Measurement of the dissymmetry of scattering in the light-scattering method gives information about the average distance between the end of molecules. According to theory, the square of the distance *d* is proportional to molecular weight *M* (or, in other words, $M/d^2$ is a constant), and this relationship holds quite accurately for some molecules such as polystyrene. With other polymers such as polyvinyl acetate, $M/d^2$ is not constant; that is, for a given molecular weight *d* is subject to considerable variation. This can only be due to the formation of branched-chain molecules, and the higher the value of $M/d^2$ the greater the degree of branching. A further confirmation of this point of view comes from the observations that, if polymers of a given molecular weight are synthesized at a series of increasing temperatures, *d* gets smaller and smaller; that is, branching becomes more pronounced.

Unfortunately, light-scattering theory is not yet in a position to interpret these results quantitatively, and hence a method of synthesizing branched-chain molecules of known structure is necessary. This can be done in the following way. A truly linear polymer is made at a low temperature. It is then dissolved in the monomer from which it was originally derived except that one of the carbon atoms is made radioactive. Polymerization is then carried out at a much higher temperature, when transfer to polymer occurs, with the result that radioactive branches are grafted on to the linear polymer. Thus the radioactivity so acquired is then a quantitative measure of the amount of branching that occurs.

The study of three-dimensional molecules is in a much less advanced stage. The only problem that so far has been quantitatively solved in some cases is the determination of the length of the polymer chain between cross-links. This is done by measuring the extent to which the polymer swells in a given liquid. Using knowledge derived from a study of the interaction of linear polymers and the same solvent, it is possible to compute the amount of branching which has taken place.

# PRESSURE OF RADIATION[*]

By Prof. R. V. JONES, C.B., C.B.E.

Department of Natural Philosophy, University of Aberdeen

MECHANICS is the firmest branch of classical physics; and sooner or later each of the other branches was linked with mechanics by an experiment which usually proved vital to the new branch. In electrostatics, for example, Priestley's discovery in 1766 of the inverse square law governing the mechanical force between two electric charges made electrostatics into an exact science; there were similar events in magnetism (Michell, 1750) and in current electricity (Oersted, Biot and Savart, Ampère, 1820), and in heat the linking experiments were those of Joule (1840–50). One reason for the importance of all these great experiments is obvious: as soon as any connexion was established between mechanics and some new branch of physics, the magnificent system developed by Newton could be readily applied to the new branch.

The history of the study of light, however, was different. For, although Kepler[1] suggested in 1619 that light might exert a mechanical pressure, the experimental difficulties in the path of direct confirmation were insuperable for nearly three centuries. Without any such aid as a telescope or camera, Kepler had observed that the tail of a comet always streams out from the head in a direction which is primarily not along the comet's previous track like the trail of a celestial paper-chase, but which points almost exactly away from the sun. This can be seen from Fig. 1, where the telescope has been turned to follow the comet, thus drawing out the images of the fixed stars into streaks in the direction of the comet's motion. The tail is nearly perpendicular to this motion, as though blown sideways by a strong wind emanating from the sun. Kepler suggested that this wind might be due to light. While we are not sure that this 'light-wind' would be strong enough to cause the effect observed (material particles might contribute more to the wind than light does), Kepler's discerning observation and stimulating conjecture are the origin of the study of light-pressure.

Kepler's work was known to Newton, who accepted the observations; but Newton[2] pointed out that a comet's tail might equally well be likened to vapour rising from a body heated by the sun. However, the idea of light-corpuscles carrying momentum with them in a 'light-wind' was so appealing that a direct experiment was bound to be made. The first recorded attempt was that of Homberg[3] (1708), who believed that he had discovered the effect; but de Mairan and du Fay[4], who carried out a more serious experiment about 1750, failed to confirm Homberg's finding.

Michell, the inventor of the torsion balance, also attempted to detect the pressure of light in about 1750; his work was described by Priestley[5]. Michell did not actually use the torsion balance, although in the hands of later experimenters this proved to be a

[*] Substance of a Friday Evening Discourse given at the Royal Institution on March 6.

Fig. 1. Comet Morehouse (1908 III), September 29, 1908. Taken with the 30-in. reflector at Greenwich. Reproduced by permission of H.M. Astronomer Royal

vital device in observing the effect. Michell himself used a suspension resembling a compass needle with a thin vane mounted at one end. On to this vane he focused the rays of the sun and found that the vane moved. What he observed, almost certainly, was an effect due to convection currents in the air surrounding the heated vane; such currents have frequently been a serious cause of disturbance in delicate experiments.

The most obvious way of reducing convection currents was to place the vane in an evacuated chamber. This step was taken by Bennet[6] (1792), who found that he could then detect no repulsion distinguishable from the effects of direct heating. From his careful experiment with its negative result, he speculated against the corpuscular theory; and he was followed by Thomas Young[7] who, in his celebrated Bakerian Lecture of 1802, quoted with approval Bennet's conclusion that the absence of light pressure was evidence in favour of light being a wave and not a corpuscular motion.

Young's statement was slightly curious, since Euler[8] (1742) had already conjectured that waves would exert a force against an opposing surface. It is therefore worth looking at both the corpuscular and the wave model. A moving corpuscle will obviously give an impulse to an opposing surface, and a stream of corpuscles, such as the bullets from a machine gun, will exert the equivalent of a steady force. It is not so obvious that a succession of waves will do the same thing, although we have only too much practical experience of the mechanical effects of single shock waves in blowing down buildings. A succession of small shock waves, such as can be generated by a repeated electric spark, can be focused by a mirror to produce impulses strong enough to turn a small paddle wheel.

A succession of longitudinal sinusoidal waves (continuous sound waves of about 3,000 c./s. are suitable) can be shown experimentally to repel a suspended vane (Pohl's sound radiometer). At first sight it is not easy to see why such a wave should produce this effect, because it can be conceived as producing a series of alternate pushes and pulls as the compressions and rarefactions strike the surface, and in free space the compressions and rarefactions are usually regarded as equal in magnitude. Near a surface, however, in order to preserve equality of motion in the forwards and backwards displacement of individual particles, the pressure rise on compression exceeds the fall on rarefaction. There is, therefore, a small net push on the surface.

Finally, the simplest model of transverse wave can be shown to exert a force by the device of Fig. 2. Transverse waves generated at $H$ on a string and travelling towards the fixed end $S$ are damped out by a pair of pulleys $P$ and $P'$. In any general position of the string such as that illustrated, there is a resultant force $R$ on one of the pulleys due to the two tension forces $T$ acting on it, and $R$ is always a component acting away from $H$. The pulleys thus tend to move away from $H$ under 'radiation pressure', and the effect can be demonstrated if the pulleys are mounted on a lightly constructed boat floating in a trough of water.

From all these examples it appears that waves are just as capable of exerting a force as corpuscles are. The argument of Bennet and of Young was therefore incorrect; the reason why the pressure of light was still undiscovered was mainly that it was too small to be isolated from the various disturbing effects.

In 1873 it almost looked as though Crookes[9] had detected the pressure of light, when he made a blackened surface in an apparent vacuum move under the influence of light. This, however, turned out to be the 'radiometer effect' which is due, very roughly, to the molecules still left in the 'vacuum' hitting the heated surface and coming off at greater speed. Any doubt about the origin of the radiometer effect was quickly removed by an elegant experiment of Schuster[10] which showed that for any action on the vane there was an equal reaction on the gas.

1873 was also the year in which Maxwell's "Treatise on Electricity and Magnetism" was published. Maxwell showed that it was possible for electromagnetic waves to travel through the ether, and that these waves would be made up of transverse alternating electric and magnetic field vectors mutually perpendicular to one another. Maxwell[11] also showed that there was a pressure in the medium carrying the waves, and that this pressure was exerted normally to the wave fronts, and he assumed that this pressure would be transmitted to any surface on which the waves were incident. J. J. Thomson[12], in a footnote to the third edition of Maxwell's "Treatise", made the assumption more plausible by proposing a mechanism whereby the force would be communicated to a conducting surface. The alternating magnetic field of the wave would induce a current in the conductor, and the field of the induced current would react back on the inducing

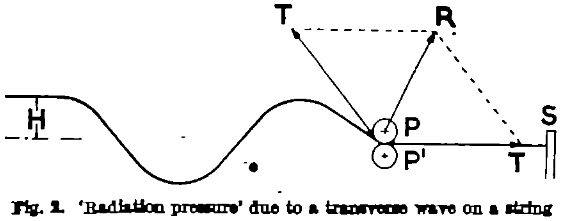

Fig. 2. 'Radiation pressure' due to a transverse wave on a string

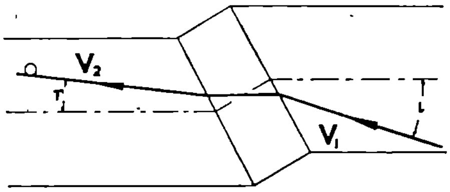

Fig. 3. Corpuscular model of refraction

field so as to cause a repulsion between the wave and the conductor. Maxwell's theory, with its impressively simple result, enabled him to calculate the repulsion due to light under any given conditions. Full sunlight falling on a black surface on the earth would, for example, exert a pressure of about $5 \times 10^{-5}$ dyne/cm.$^2$, which is about the same pressure as would be generated gravitationally by a single layer of atoms spread over the same surface.

Maxwell's calculation showed the experimenters how minute a force they would have to observe (Osborne Reynolds[13] calculated that it was about a thousand times as small as the Crookes radiometer effect), and it took another twenty-six years before Lebedew[14] in Russia and Nichols and Hull[15] in the United States were able to show that pressure of the predicted amount was in fact exerted by light. The difficulties that they had to overcome were threefold: to make suspensions so delicate that they would turn appreciably under the small forces involved; to defeat convection troubles; and to eliminate the 'radiometer' effect. The last two troubles were overcome simply by improving the vacuum. With the successful outcome of these experiments, the link between light and mechanical force was finally established.

There is an interesting consequence of the pressure of light: light must carry momentum, as was first seen from the electromagnetic point of view by J. J. Thomson[16]. A body emitting light is therefore giving momentum to it, and hence there must be a reaction on the emitting body. This reaction was detected by Poynting and Barlow[17], who described their experiment in the Bakerian Lecture for 1910.

Although under terrestrial conditions the pressure of light is very small, it is of great significance. The fact that light carries momentum enabled Einstein[18] to give a convincing illustration of the equivalence of mass and energy. Light pressure is thought to be a vital factor in the structure of stars, and to set an upper limit to their size. The radiation pressure outwards at the surface of a star tends to increase with stellar size at a greater rate than does the gravitational pull inwards at the surface. Above a critical diameter, therefore, an atom on the surface tends to be blown away by radiation rather than retained by gravity.

An interesting effect of a refracting surface on the momentum of radiation can be predicted and observed; this is easily seen from a model which demonstrates the corpuscular theory of refraction. The model (Fig. 3) consists of two level planes at different heights, separated by an incline; the lower plane corresponds to the optically denser medium, and the incline to the optical interface. If a ball is rolled over the upper plane towards the lower one with constant speed, $V_1$, it gains speed down the incline by an amount which is independent of the angle of approach, $i$. It therefore emerges across the lower plane with constant speed $V_2$ at an angle $r$ to the normal, and it is easy to see that

$$\sin i/\sin r = V_2/V_1 = \text{a constant.}$$

The model thus obeys Snell's law, and it can also be made to show the phenomena of critical angle and total internal reflexion. It is, in fact, the simplest example of the type of model used in the investigation of electric optics.

The model is, of course, imperfect, as can be seen from its implication that light travels faster in a denser medium; but since no model can be perfect, this one—which has been shown to be in several respects satisfactory—should not be completely rejected without further trial. In particular, it predicts that the momentum of the corpuscles is greater in the denser medium by a ratio equal to the refractive index. A stream of corpuscles will therefore impinge with a greater momentum on a surface immersed in the denser medium than the same stream would have done in the rarer medium. A corresponding prediction is made by the wave theory, since the radiation pressure is equal to the energy per unit volume, and this obviously increases as the waves slow down in the denser medium. Finally, since the momentum of an individual photon is $h/\lambda$, where $h$ is Planck's constant and $\lambda$ the wave-length, this momentum is greater in the denser medium since $\lambda$ is now smaller in the ratio of the refractive index.

All theories, therefore, make the same prediction: when light passes into a denser medium it gains momentum so that the ratio of the final momentum to the initial momentum is equal to the refractive index. Since momentum is conserved, there must be

a reaction on the surface separating the two media, directed from the denser to the rarer medium. This can easily be seen from the corpuscular model. The reaction was observed experimentally by Barlow[19] (1912).

Recently the increase in momentum of the light itself has been directly observed at Aberdeen, the preliminary form of the experiment being already summarily reported[20]. The experiment has involved comparing the forces exerted by a beam of light on a small vane suspended by a torsion balance, first in air and then with the same beam and the same vane immersed in various liquids. Previous determinations of radiation pressure have almost all been made *in vacuo* because of the difficulties due to convection currents in air, but the present experiment requires that the pressure should be measured in liquids, where convection troubles and other thermal effects are likely to be much more acute than in any gas. Fortunately, it is possible to distinguish the effect of radiation pressure from the other effects by the fact that it is instantaneous, whereas the others, being thermal, take a few seconds to develop fully, depending on such factors as the heat capacity of the vane. A quickly responding suspension is therefore required, and one with a response time of about half a second was used. Convection troubles were minimized by making the suspension small (the reacting vane was of rhodium-plated silver, 5 × 2 × 0·1 mm.) and mounting it in a narrow (8-mm. diameter) tube, as shown in Fig. 4. A stretched suspension was used, for it would have been impossible to operate a vane suspended from above only, because surface tension would have dragged it to the side of the containing tube. A second mirror was added at the top of the suspension to enable the orientation to be observed. A minor problem was the technique of assembly of the suspension, since this had to be immersed in several liquids, and could therefore contain no cement soluble in any one of them. To minimize effects due to thermal causes, the experimental arrangement was made as symmetrical as possible. Two light beams were first thrown on to the vane (suspended symmetrically with its face vertical and its longest edge horizontal) in positions *AA′* so as to generate an anti-clockwise couple on the vane; the light beams were then rapidly moved to positions *BB′*, where they would generate an equal clockwise couple.

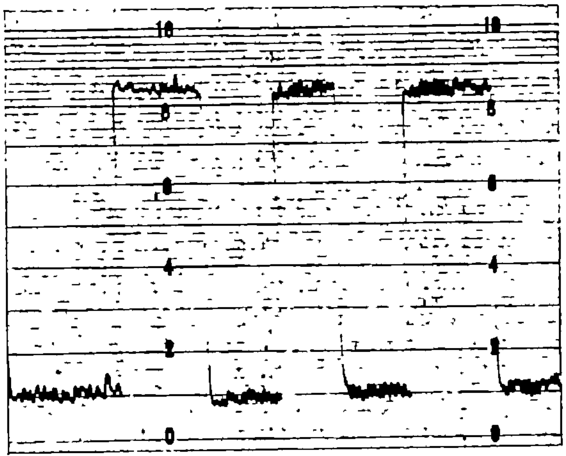

Fig. 5. Record of deflexion due to radiation pressure of light in air. Magnitude of deflexion, 5 × $10^{-5}$ radian. Disturbances probably Brownian

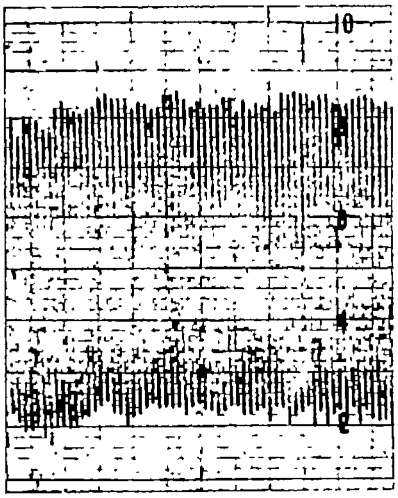

Fig. 6. Record of deflexion due to automatic switching of light in liquid (xylene)

Owing to the quick response required in the suspension, it was necessarily insensitive, and the typical change in orientation caused by moving the light beams was of the order of 5 × $10^{-5}$ radian, equivalent to the movement of a galvanometer spot of 0·1 mm. at a scale distance of 1 m. Incidentally, this is only about fifty times the root mean square of the Brownian fluctuations in the system. Both they and the change in orientation consequent upon moving the light beams can be seen in Fig. 5, which shows a record taken with air in the tube. To obtain satisfactory records of such small movements, it was necessary to use an optical lever amplifier; this had already been developed for other purposes[21], and it could, if necessary, be made so sensitive that with a mirror 5 mm. in diameter it would detect reliably a rotation so small that no part of the mirror moved by more than about 2 × $10^{-10}$ cm., or about one-hundredth of an atomic diameter.

The deflexions in liquids were not nearly so easy to interpret nor was the zero nearly so steady; but it was noticed that the first kick after moving the light beams was roughly of the correct magnitude, and it was thus possible to obtain preliminary observations of the increase in pressure in liquids. In order to isolate the immediate kick due to radiation pressure, it was decided to switch the light beams mechanically about once per second, so that an oscillating record (Fig. 6) was obtained. The air and liquid records could not then be compared directly, because of the increased damping of the oscillations of the vane in the liquid. This difficulty could be simply overcome by adding a very small magnet to the suspension, and arranging to deflect it by a magnetic field which reversed with the same frequency as that at which the light beam was switched. In principle it would have been possible to arrange the light and magnetic deflexion in anti-phase, so that the strength of current generating the magnetic field required to balance the light pressure could have been taken directly as a measurement of the latter pressure. Since the vane would then be at rest both in air and in liquid, no damping effects would have had to be allowed for. In practice, however, it was easier to find the alternating deflexion due to the light pressure, and then to find the current required to produce an equal alternating deflexion in the same

VARIATION OF RADIATION PRESSURE WITH REFRACTIVE INDEX

| Liquid | Water | Ethyl alcohol | Carbon tetrachloride | Xylene | Benzene | Carbon disulphide | Standard error (per cent) |
|---|---|---|---|---|---|---|---|
| Observed reflexion ratio | 1·274 | 1·305 | 1·413 | 1·424 | 1·432 | 1·539 | ± 1·5 |
| Corrected pressure ratio | 1·348 | 1·374 | 1·478 | 1·502 | 1·517 | 1·637 | ± 2 |
| Mean refractive index | 1·329 | 1·358 | 1·457 | 1·489 | 1·493 | 1·613 | ± 0·1 |
| Discrepancy (per cent) | +1·4 | +1·2 | +1·4 | +0·9 | +1·6 | +1·5 | |

medium. This method again eliminated the viscosity of the medium.

The foregoing experiment has been carried out by Mr. J. C. S. Richards (University of Aberdeen), aiming at an over-all accuracy of one per cent. For this accuracy, many observations (more than four hundred) were necessary on each liquid, to average out the effects of Brownian and other disturbances. It was also necessary to allow for effects such as the slight change of reflectivity of the vane on immersion in liquid, and the loss of light in the medium as it crosses the glass/air or glass/liquid interfaces on its way to the vane. Mr. Richards's results are shown in the table.

This table shows that the proportionate increase in momentum is within 1 to 1·5 per cent of the refractive index, the experimental results being consistently high by a small amount which is probably due to some unforeseen correction that we have not allowed for. The agreement is amply good enough, however, for us to conclude that the effect has been satisfactorily confirmed. Not only, therefore, does light press against a mirror but it also gains or loses momentum whenever it crosses a refracting boundary.

# OBITUARY

## Dr. G. F. Herbert Smith, C.B.E.

GEORGE FREDERICK HERBERT SMITH was born on May 26, 1872, eighty-one years ago. Well known to mineralogists for his early work on geometrical rystallography and on the scientific study of gemtones, he was better known to a wider circle for his work as honorary secretary of the Society for the Promotion of Nature Reserves and numerous other ouncils and committees having to do with the preservation of wild life and the protection of Nature. Most of this work, however, was done in the fifteen years since his retirement from the Natural History Museum, where he had served successively as assistant in the Department of Mineralogy, assistant secretary and secretary of the Museum and keeper of minerals for a total of forty years.

Herbert Smith came to the Department of Mineralogy at twenty-five by way of Winchester and New College, Oxford, with firsts in the finals honours schools in mathematics and physics. He spent part of a year at Munich studying under Paul Groth, and at the Museum he produced some important papers on geometrical crystallography and devised a three-circle goniometer which he used for working out the intricate problems of the crystallography of the gold telluride, calaverite (1902), and the sulpharsenite of lead, sartorite, from the famous Binnenthal locality. Early in his career at the Museum he became interested in the study of gemstones and scientific methods of identifying faceted stones. To this end he designed a convenient form of refractometer and put in the hands of jewellers an instrument that all could use effectively with very little difficulty. From 1912 he was one of the examiners for the diploma in gemmology initiated by the National Association of Goldsmiths and so remained after its Education Committee became the Gemmological Committee in 1924 and finally formed the Gemmological Association in 1931. He was president of the Association in succession to Sir William Bragg from 1942 until his death. Among gemmologists his name is a household word, and his book "Gemstones", now in its twelfth edition, contains the record of his accumulated knowledge and experience in the scientific study of gemstones both as minerals and as gems.

After the death of Charles E. Fagan in 1921, Herbert Smith left the Department of Mineralogy to become assistant secretary of the Museum. Thenceforward he became involved in administrative work. During the early part of his period in this office an important event was the move in 1924 of the zoological collections preserved in spirit into the completed eastern half of the New Spirit Building. It was probably thanks to Herbert Smith's efforts that the Empire Marketing Board made a generous grant to enable a third quarter of this building to be completed in 1930 to provide accommodation for the overcrowded Department of Entomology pending the erection of its own building (which was in the event not completed until 1952 although the south half was occupied in 1936). Some of the work of preparing evidence for the Royal Commission on Museums and Galleries in 1927 fell to Herbert Smith, and he also had the congenial task of arranging for the celebration of the fiftieth anniversary of the opening of the Natural History Museum (1931). Several collecting expeditions in East Africa were organized during this period, culminating in the successful 'Ruwenzori' Expedition by the late F. W. Edwards and Dr. George Taylor in 1934. Accounts of these expeditions were published in the *Natural History Magazine*, a museum publication which Herbert Smith edited throughout its short life during 1927–36. The preparation and sale of postcards illustrating specimens in the collections was another of Herbert Smith's innovations and was completely successful.

He did many things to encourage a corporate spirit in the Museum staff, strongly supporting the formation of a sports club and rifle club, of which latter he was himself an active member. With three other senior members of the staff he organized the staff association for the scientific staff. This association was affiliated to the Society of Civil Servants, of which Herbert Smith was one of the honorary secretaries, 1918–25. He was also editor of its journal, 1923–30, and later a vice-president and president, 1929–32. It was typical of Herbert Smith that, in connexion with this work for the Society of Civil Servants, he arranged a special train to take its members and other Civil servants to Richmond, Yorkshire, to view the total eclipse of the sun in 1927. He wrote a guide to the eclipse and provided "pieces (5 by 2 ins.) of dark glass for viewing the Sun". It was no fault of his that cloud obscured the view.

The Civil Service Arts Council he served for fifteen years as honorary secretary and treasurer, and he also served on the Civil Service Sports Council and was chairman of its publicity committee from 1946. As another spare-time activity he represented the Trustees of the British Museum on the Council of the Royal Albert Hall from 1930 until his death, and was chairman of the Executive Committee, 1941–47, and a member of the Finance Committee, 1941–51.

In the last two years of his service in the Museum, he returned to the Department of Mineralogy as keeper and did some good work in arranging new exhibits of gemstones and semi-precious stones in specially illuminated cases. These unfortunately had to be dismantled only two years later on the outbreak of war so that the specimens could be put in a safer place.

Herbert Smith's work for the Society for the Promotion of Nature Reserves began in 1921 when, succeeding Charles E. Fagan in the Museum Office, he took over also the secretarial work of the Society. During his long term of office, the activities of the Society greatly increased. It was this Society that took the initiative in 1941 of getting together a conference to consider Nature protection in post-war reconstruction. This conference in its turn appointed, at the suggestion of the responsible Minister, the Nature Reserves Investigation Committee in 1942. Of both these bodies Herbert Smith was honorary secretary, and he was also chairman of the Geological Reserves Sub-Committee. These committees co-ordinated the work of no less than twenty-four regional committees in England and Wales. Two reports were issued in 1945, shortly after the end of the War, and their detailed recommendations were almost all incorporated in the report of the Wild Life Conservation Special Committee presented to Parliament in 1947[1,2]. The establishment of the office of Nature Conservancy was a direct outcome of the recommendations of this Committee.

Herbert Smith had been chairman of the Wild Plant Conservation Board since 1931 and was interested, too, in the Society for the Preservation of the Fauna of the Empire and the Convention for the Protection of the Fauna and Flora of Africa. In a wider field he was one of the British delegation to the International Conference for the Protection of Nature held at Brunnen in 1947[3] and of the later conference of Government representatives held at Fontainebleau under the auspices of Unesco in Paris during the following year. There he was chairman of the committee charged with the drafting of the constitution. His committee completed its task in two days and the finished draft was ready for the closing session. He attended the first General Assembly in Brussels in 1950 as head of the British delegation, and since that year he held the office of a vice-president of the Union.

Herbert Smith had outlived most of the friends who had known him as a young man. To many who served on his committees he may have seemed reserved, autocratic and obstinate. He was, in fact, determined to get things done and he usually succeeded. He understood what things were practicable, and by hard work and persistence he accomplished much. That was his reward for the devotion with which he worked for the protection of Nature, to which cause he gave, voluntarily and unpaid, almost all his time for the fifteen years that followed his retirement from the Natural History Museum.

He died after a short illness on April 20, 1953, and leaves a married daughter. His wife, a daughter of the late John Ellerton, of Leamington, died in 1936. He was a Fellow of the Royal Astronomical Society, a member and a past vice-president of the Mineralogical Society, and for many years a Fellow of the Geological Society and a member of the British Association. He was awarded the C.B.E. in 1949.

W. Campbell Smith.

# NEWS and VIEWS

## Geography at Glasgow: Prof. A. Stevens

The retiring professor of geography in the University of Glasgow, Prof. A. Stevens, commenced his long association with the University as an arts student and graduated M.A. in 1907. After a short break, he continued his studies in the Faculty of Science and obtained his B.Sc. as a geologist. In 1914 he joined Shackleton's South Polar expedition, and was marooned for two years in the Antarctic. On returning home Stevens served with the Army until the end of hostilities. In 1919 he was invited to organize a Department of Geography at Glasgow; a lectureship had been established in 1909 but was in abeyance. It was not until as late as 1947 that a chair of geography was established with Stevens as the first professor. He has devoted his energies very largely to the development of the Department on what he believed to be a sound basis; the emphasis has been on regional geography. At the same time, he has contributed notably by papers and in discussion to theoretical aspects of his subject; his presidential address to Section E (Geography) at the British Association in 1939 is an example. Prof. Stevens has not been a prolific writer; but his papers have covered a wide field and each has been a stimulus to his fellow workers. There have been contributions of lasting value on physical geography in which his earlier interests undoubtedly lay, and latterly papers to the Institute of British Geographers have dealt with problems of population distribution in the British

Isles. He has also been directing research on a hypsometric survey of Scotland, and it is hoped that his retirement will not cut short this work.

### Dr. Ronald Miller

RONALD MILLER, who is to succeed Prof. Stevens at Glasgow, was the first member of the University of Edinburgh to graduate as M.A. with honours in geography, in 1931. As an Orcadian naturally interested in the sea, he then turned appropriately to oceanography and, after two years as a Carnegie Research Scholar, working in the Marine Laboratory of the Fishery Board in Aberdeen and on its research vessel, he earned the degree of Ph.D.(Edin.) for his contribution to the hydrography of the northern North Sea. As an assistant lecturer in geography under Prof. H. J. Fleure at Manchester (1933–36), he developed an interest in cartography, a subject on which he has since published several papers. He then entered the Colonial Service as geography specialist at Katsina Higher College, Nigeria, which was intended eventually to attain university college status. Working with African students in the field, he published studies of the Hausa and was engaged in further research on Nigeria when the Second World War supervened and he was embodied from the Supplementary Reserve into the Nigeria Regiment, where he served until 1944 and then reverted to civil employment at the request of the Colonial Office. He visited many parts of West Africa and acquired an intimate knowledge of the Hausa people and fluency in their language. He returned in 1946 to his Alma Mater as lecturer under Prof. A. G. Ogilvie, and has been primarily concerned with physical aspects of geography and with departmental work in the field. He has written on African topics and is continuing his work on Nigeria.

### Harrison Howe Lecture : Prof. H. C. Brown

THE Harrison Howe Lecture for 1953 of the Rochester Section of the American Chemical Society will be delivered on November 21 by Prof. Herbert C. Brown, professor of chemistry in Purdue University, Lafayette. The Lecture was founded in 1945 to commemorate the services to chemistry of Harrison E. Howe and his influence on American industry through his researches. Prof. Brown has been chosen this year for his contributions to stereochemistry and also for his work in the synthesis of hitherto unknown boron hydride derivatives. In the field of stereochemistry his studies have shed new light on the abnormal behaviour of strained molecules, and recently he has developed a method of measuring the magnitude of the strain factor in structurally related compounds. His work on the chemistry of boron hydride was conducted at the University of Chicago during the Second World War as part of a war-time project connected with atomic energy research and is noteworthy for the preparation of a new type of organoboron substance which is very useful as a reducing agent and source of hydrogen.

### Advisory Council on Scientific Research and Technical Development

THE Ministry of Supply announces the following appointments to the Minister's Advisory Council on Scientific Research and Technical Development: Prof. H. W. Melville, Mason professor of chemistry in the University of Birmingham; Prof. J. L. M. Morrison, professor of mechanical engineering in the University of Bristol; Prof. L. Rosenhead, professor of applied mathematics in the University of Liverpool; Prof. I. N. Sneddon, professor of mathematics in the University College of North Staffordshire; Prof. A. R. Todd, professor of organic chemistry in the University of Cambridge.

### Committee on Adult Education

MISS HORSBRUGH, Minister of Education, has appointed the following committee to inquire into the adult educational service of Great Britain: Dr. Eric Ashby, vice-chancellor, Queen's University, Belfast (chairman); Mr. A. L. C. Bullock, censor of St. Catherine's Society, Oxford; Prof. W. L. Burn, professor of modern history, University of Durham; Mr. T. Mervyn Jones, chairman, Wales Gas Board; Sir Wilfrid Martineau, formerly chairman of the Birmingham Education Committee; Mr. C. M. Skinner, a member of the Court of Governors, University of Manchester; and Mr. G. B. Thorneycroft, member of the General Council of the Trades Union Congress. The committee's terms of reference are: "To review the present system by which the extra-mural departments of universities, the Workers' Educational Association and the other responsible bodies provide local facilities for adult education, with special reference to the conditions under which these facilities are organized and are aided by grants from public funds; and to make recommendations".

### Technological Education in Britain

THE reply of Mr. Kenneth Pickthorn, Parliamentary Secretary to the Ministry of Education, to an adjournment debate on technological education, initiated by Mr. James Johnson on May 21, did not indicate that the Government has yet formulated any real policy. Mr. Pickthorn rightly pointed out that there had not yet been much time for technical colleges to obtain grants, or promises of grants, under Circular 255, but he could only express the hope that colleges with courses which attract the maximum—the advanced rate of grant of 75 per cent—would develop more and more into institutions for technological work only, and that the remaining colleges would concentrate on the needs of technicians. Mr. Johnson had particularly stressed, besides the desirability of developing the work of the major technical colleges (some thirty of about two hundred), the shortage of science teachers in secondary schools, pointing out that in 1951 not one of the 51 honours graduates in the honours school of chemistry at the University of Oxford went into teaching. Mr. Pickthorn said he thought that the quantitative shortage of science teachers is being exaggerated; indeed, the situation is slightly improving. He emphasized the impossibility of finding a rapid solution of this problem.

### City and Guilds of London Institute : Report for 1951

THE annual report of the council of the City and Guilds of London Institute for 1951 (pp. 64; 1952), in referring to the election of the Duke of Edinburgh as president, recalls that in 1881 the Prince of Wales became the first president and that the office has remained vacant since he became visitor and patron on accession to the throne in 1901. The report records a year of consolidation, but no long-term solution of the acute problem of accommodation is possible until the resources of the Institute are considerably increased. The council is desirous that the Institute's work in the field of art should be more widely known and appreciated. Honorary associate-ships were conferred on nine professors of not less than five years standing at the College, and the fellowship was conferred on Atholl Blair and H. Shoosmith. A Finsbury Medal has been instituted at the instance of the Finsbury Technical College Old Students' Association, and this body, in terminating the Streatfeild Memorial Lectures, has also offered the balance of the Fund to establish a major annual prize in a suitable branch of chemical technology, if possible where emphasis can be placed upon practical work. The first new Insignia awards (see *Nature*, 170, 828; 1952) were expected to be made during the winter of 1952, and the Institute believes that the introduction of the award will encourage students to take full advantage of the facilities provided in industry and technical colleges and lead to recognition of the value of practical training and experience. A deficit of £6,278 on the year and depreciation of the Institute's investments threaten curtailment of activities unless new income can be found.

## Jubilee of the School Nature Study Union

The latest issue of the School Nature Study Union journal (*School Nature Study*) represents a memorable event in the life of the organization—its fiftieth birthday. The Union was founded in 1903, largely owing to the enthusiasm of the Rev. Claude Hinscliff and Miss Kate Hall, and soon became the means of promoting considerable interest in the study of natural history in schools. The first president was Sir George Kekewich, and the vice-presidents included Lord Beauchamp, Sir John Cockburn, Sir Lauder Brunton, Mrs. Humphrey Ward and, later, Mr. H. G. Wells. During its life, many eminent biologists have served the Union as presidents or in other capacities, although probably no names are more pre-eminent than those of Miss C. Von Wyss and Mr. H. E. Turner, who were both members of the original committee formed in 1905 until their resignation in 1936. Besides the journal, which has been appearing for forty-eight years, the School Nature Study Union has performed a most useful service to teachers and others in the production of an extensive series of leaflets which give practical advice on how to teach natural history more effectively. Cordial greetings are extended to the School Nature Study Union in its jubilee year.

## Botanical Gallery at Bolton

Though the Museum and Art Gallery at Bolton was built just before the War it was only possible recently to install a botanical gallery. This is described in the *Museums Journal* for May by Mr. A. Hazelwood and indicates clearly some of the aspects of botany which can be so illustrated. Naturally recourse to modelling was considered essential, and the first exhibit is an enlarged model of a poppy which is used for demonstrating terms applied to the various parts of a flowering plant. Other exhibits deal with the morphology and some aspects of the physiology of the flowering plant, root forms, shoot forms, nutrition and adaptation to specialized environments, together with the fruit, dispersal and germination of a variety of plants. Another section is systematic and, after a series of colour transparencies of microscopic forms, follows with models of the larger thallophytes to the Angiosperms. Emphasis is given to the illustration of forest trees, and the series concludes with exhibits showing plants as food.

## Herbarium of Indian Plants

The discovery of an important herbarium in a recent acquisition by the Liverpool Public Museums is related by Mr. H. Stansfield, keeper of the Department of Botany, in the March number of the *Museums Journal*. This collection, which was given by the Liverpool Chemists' Association, consisted of several thousand specimens with no data, and by patient investigation Mr. Stansfield has been able to record its history. By noting various clues and following several lines of investigation, he was able to prove that the plants were those on which the text and illustrations of J. F. Royle's "Illustrations of the Botany of the Himalayan Mountains and the Flora of Cashmere" were founded. Some of the plants were collected in the plains of India of the north-west provinces, some are from the mountainous tract between the Sutlej and the Ganges and others from the valleys of Kashmir (Cashmere). The plants from the last-named locality were obtained during 1828–31 by native collectors. The herbarium with its important type-specimens has been placed in good order and will no doubt be consulted by many workers.

## Feeding Mechanisms in Deep-Sea Fish

Much of our knowledge of the habits and functioning of deep-sea fishes must, perforce, be derived from indirect evidence. From dissections of preserved material, the late Dr. V. V. Tchernavin has carefully reconstructed the probable sequence of movements involved in feeding in a bathypelagic stomiatoid teleost *Chauliodus*. His conclusions have now been published by the British Museum (Natural History) in a volume entitled "The Feeding Mechanisms of a Deep-Sea Fish *Chauliodus sloani* Schneider" (pp. viii+101+10 plates; 1953; 30*s*.). Jaw and head movements, basically similar to those of other teleosts, but on a much exaggerated scale, enable *Chauliodus* to capture and ingest prey larger than itself. For comparison with *Chauliodus*, the feeding mechanisms of certain other vertebrates are described briefly. Other valuable details described in the volume are the operation of breathing valves, the distribution and possible significance of light organs in *Chauliodus*, and the dissimilar feeding mechanism of another bathypelagic teleost, *Saccopharynx* (order Lyomeri). There is an extensive bibliography.

## Linen Research Association: Report for 1952

The report of the council of the Linen Research Association for the year ended September 30, 1952 (pp. 24; from the Association, Lambeg, Northern Ireland; 1952), records steady progress in almost every section of the Association's activities. Research on flax production has again been a matter of concern to the industry, and the council records its thanks to the Flax Development Committee for continued support of its research on flax scutch. The flax-production scheme in England is now to continue on a permanent basis, and also research work in Norfolk, but on a reduced scale. In the work on rayon staple, various causes of shading faults in plain dyed fabrics have been revealed and recommendations made for reducing the faults to a minimum. Arrangements have been made for the manufacture of the Linra photo-electric yarn irregularity gauge to assist in keeping yarn irregularity below a fixed level, and comparative tests of the Linra modified roller-breaker against other breakers are being arranged. Surveys in factories have been specially directed to the investigation of yarn-winding processes and of humidification. In sizing, promising results have been obtained in trials of a new brushing unit on a slashing machine, and fundamental work on the relationship between yarn and cloth has continued. Methods of bleaching linen goods have been evolved which indicate that still higher quality can be achieved.

## Fluorosis and Pollution

REPLYING to an adjournment debate in the House of Commons on May 14, initiated by Dr. Barnett Stross, of Stoke-on-Trent, who pressed for the instigation of a local inquiry into the incidence of fluorosis due to atmospheric pollution, the Parliamentary Secretary to the Ministry of Health, Miss Patricia Hornsby-Smith, said that, on the evidence available, neither the Ministry nor the Medical Research Council believes that an inquiry in that area is essential. The wider problem of fluorine would, however, have to be one of the items covered in the investigations now being undertaken by the Minister of Housing and Local Government into air pollution, as particularly applied to industrial areas. With regard to the question of fluorine in water supplies, Miss Hornsby-Smith said she did not wish to make any comment pending a full study of the report of the British mission to North America inquiring into this question.

## X-Rays accompanying μ-Meson Capture

INTERESTING observations on the X-rays accompanying μ-meson capture by nuclei are reported through the rather unusual channel of a 'press release' from Columbia University. Negative μ-mesons brought to rest in matter eventually disappear, either by spontaneous decay or by nuclear capture. In either case the process takes place in two fairly distinct steps. First the meson is attracted into quantum orbits around a nucleus, to which it is bound by the electrical forces. During this stage it emits X-rays or ejects atomic electrons as it jumps successively from one quantum state to another, until it reaches the state of lowest energy. Disintegration or capture then occurs. The orbits are like those of the interior atomic electrons, but about two hundred times smaller in linear dimensions (a consequence of the greater mass of the meson). The energy of the X-rays is similarly some two hundred times greater than the corresponding atomic X-rays. Rainwater and Fitch have observed these X-rays and made precise determinations of their energies. Since the deepest meson orbit and the nucleus are comparable in size for a heavy nucleus, the energy of the former is strongly influenced by the way in which electric charge is distributed in the nucleus. From their measurements Rainwater and Fitch conclude that the charge is considerably more concentrated towards the centre than had been previously believed. They deduce an *effective* radius 15 per cent smaller than is yielded by such methods as nuclear binding energies or neutron scattering.

## Industrial Application of Aerodynamic Techniques

A NUMBER of special applications of aerodynamic equipment and techniques which have been used in the course of investigations in the Aerodynamics Division of the National Physical Laboratory, Teddington, are described in a little handbook entitled "The Industrial Application of Aerodynamic Techniques" (National Physical Laboratory: Notes on Applied Science No. 2. Pp. 37. London: H.M.S.O., 1952. 3*s*. 6*d*. net). It is often impossible to use the wind tunnel for the solution of problems of fluid motion which arise outside the aircraft industry. Dr. R. A. Frazer's work on the aerodynamic stability of suspension bridges is an exception, and the model tests done for the Severn Bridge project are described. Civil and mechanical engineers will deduce without surprise that there are few industrial applications of text-book aerodynamics. This is, of course, true; but one feels that opportunity has been lost by conveying a too sober estimate of the possibilities of applying aerodynamic experience to industrial practice.

## Kodaikanal Observatory: Report for 1950

THE report for 1950 of the Kodaikanal Observatory (pp. 8; Delhi: Manager of Publications, 1951; 7 annas or 8*d*.) deals chiefly with the astronomical work there, though short references are given to geomagnetic observations and seismology; the meteorological data appear in the *Indian Weather Review*, and the administrative details in the annual report of the Indian Meteorological Department. A list of the forty-seven instruments in use is given and also a brief account of the constructional works relating to development projects, including the construction of a dome for housing a 20-in. Grubb reflector and of buildings for an ionosphere laboratory. There has been a considerable amount of co-operation with other observatories—the Solar Physics Observatory, Cambridge, the Royal Greenwich Observatory, the Meudon Observatory, and the Mt. Wilson Observatory—with which there has been exchange of spectroheliograms, photoheliograms, quarterly statements of solar flares, etc. During 1950 the Government of India granted two research scholarships in astronomy tenable for three years at the Kodaikanal Observatory.

## Beit Memorial Fellowships for Medical Research

BEIT Memorial Fellowships for medical research have been awarded as follows. *Fourth Year Fellowship* (£735 a year): Dr. Joan E. Keilin (University of Cambridge), to investigate, at the Department of Biochemistry, Cambridge, the catalytic activity of hæmatin compounds and the effect of oxidizing agents on hæmatins, the properties of purified helicorubin and its relationship to other natural hæmoproteins, and the reactions of hæmatins with proteins and their constituent amino-acids and peptides, with the aim of gaining more information on the structure of the hæmoglobin molecule, the link between the hæm and globin and the use of hæmatin as a reagent for the study of other biologically important proteins. *Junior Fellowships* (£630 a year): J. R. Cannon (University of Sydney), to continue at the University Chemical Laboratories, Cambridge, the study of the chemical structure of vitamin $B_{12}$; G. P. Lewis (University of Wales), to study, at the National Institute for Medical Research, Mill Hill, London, the relationship between structure and action of drugs, particularly of antagonists of histamine, acetylcholine, adrenaline and *nor*-adrenaline, in order to examine how far ionization of a drug or its receptor modifies drug action; W. L. Nicholas (University of Liverpool), to investigate, at the Department of Zoology, Liverpool, the determination of the growth requirements of free-living and parasitic nematodes in chemically defined media, with the view of its possible application to the chemotherapy of nematode infections; Dr. Evelyn E. B. Smith (University of Glasgow), to investigate, at the Department of Biochemistry, Glasgow, the enzymic mechanisms of transfer reactions involving uridine pyrophosphate compounds containing glucose, glucuronic acid and N-acetylglucosamine, and to study the biosynthesis of glucuronic acid, glucuronides and oligosaccharides containing glucuronic acid, using carbon and phosphorus isotopes.

### Lady Tata Memorial Trust: Awards

THE following awards have been made by the Lady Tata Memorial Trust for research on leukæmia and allied diseases, to be conducted in the places indicated during the academic year beginning October 1, 1953. *Grants for research expenses or for scientific assistance:* Dr. A. Fagraeus and Dr. B. Thorell (Stockholm), Dr. C. Merskey (Cape Town), Prof. C. Oberling (Villejuif, Seine) and Dr. C. C. Ungley (Newcastle upon Tyne), renewals; Dr. J. Nordmann (Paris), new award. *Part-time personal grant and grant for technical assistance:* Dr. J. B. G. Dausset (Paris), renewal with increase. *Senior Research Fellowships:* Dr. A. R. Gopal-Ayengar (London), extension for two months; Dr. J. Kieler (Copenhagen), new award. *Scholarships (whole-time or part-time):* Dr. R. Raak-Nielsen (Copenhagen) and Dr. R. Robineaux (Paris), renewals; Dr. F. Kissmeyer-Nielsen (Aarhús) and Dr. N. A. Stenderup (Aarhus), new awards. In addition, the period of tenure of a special scholarship awarded earlier this year to Dr. Gavino Negroni (Italy), for work at the Imperial Cancer Research Fund Laboratories, Mill Hill, London, will continue until April 30, 1954.

### University of Birmingham: Appointments

THE following have been appointed lecturers in the University of Birmingham: Dr. J. H. Cort (physiology), Miss Joyce B. Grace (bacteriology), Dr. T. O. Jeffries (physics), J. B. Woodward (mathematical physics) and Dr. K. White (physiology). The following have resigned from the University: F. R. N. Nabarro, lecturer in metallurgy, on appointment to the chair of physics in the University of the Witwatersrand, Johannesburg; and Dr. A. B. L. Beznak, lecturer in physiology, on appointment to the chair of physiology in the University of Ottawa.

### American Academy of Arts and Sciences: Foreign Honorary Members

THE following have been elected foreign honorary members of the American Academy of Arts and Sciences: Prof. Arne Tiselius, professor of biochemistry, University of Upsala; Prof. A. J. Kluyver, professor of microbiology, Technical University, Delft; and Prof. D. M. S. Watson, formerly Jodrell professor of zoology and comparative anatomy, University College, London.

### Meeting of Nobel Prize-winners in Lindau

MEETINGS of Nobel prize-winners were started some years ago at Lindau, Bavaria, on the shores of Lake Constance, for the purpose of creating and developing a general contact between leading scholars in an exact science and the professional and industrial workers whose daily work is based on the results of the investigations of these scientists. The method chosen for achieving this contact is for the Nobel Laureates to give lectures adapted in their content to the needs of practical men and giving a survey on the results of scientific research to the layman. The meeting this year, to be held during June 29–July 2 under the patronage of Count Lennart Bernadotte, is devoted to physics, and eight lectures will be given as follows: June 29, Prof. M. von Laue (Röntgen-ray interferences) and Prof. G. von Hevesy (biochemical effects of ionizing radiations); June 30, Prof. O. Hahn (modern alchemy) and Prof. C. F. Powell (high-altitude flights with free balloons); July 1, Prof. F. Soddy (discovery of the natural transmutation of the radio-elements) and Prof. P. A. M. Dirac (quantum mechanics and the æther); July 2, Prof. H. Yukawa (search for a unified theory of elementary particles) and Prof. W. Heisenberg (progress and difficulties in the quantum theory of elementary particles). The general arrangement is for lectures to be given during the morning so as to leave the rest of the day free for discussion groups and for excursions and other social activities. The fee for participation in the meeting is DM 30 or DM 10 a day. Further information can be obtained from the Sekretariat der Tagungen der Nobelpreisträger, Stadttheater, Lindau-Bodensee.

### Announcements

DR. L. C. BATEMAN, deputy director of research and formerly superintendent of chemical research of the British Rubber Producers' Research Association, has been appointed director of research of the Association in succession to Dr. Geoffrey Gee, now professor of physical chemistry in the University of Manchester.

DR. ERNST MAYR, curator of the Whitney–Rothschild Collection, American Museum of Natural History, has been appointed Alexander Agassiz professor of zoology in the Museum of Comparative Zoology, Harvard University. Two other appointments are those of Mr. James C. Greenway, jun., to be curator of birds in the Museum in succession to the late James L. Peters, and Mr. Raymond A. Paynter, jun., to be assistant curator of birds.

THE Philosophy of Science Group of the British Society for the History of Science is offering a prize of £50 for the best essay of not more than 4,000 words on: "What is the logical and scientific status of the concept of the temporal origin and age of the Universe?" (for example, as used in recent cosmological work). The essay should clarify the logical, theoretical, and observational aspects of the idea of assigning a quantitative age to the universe. Essays in English, French or German (in typescript) must reach the Honorary Secretary, Philosophy of Science Group, University College, Gower Street, London, W.C.1, not later than December 1, 1953, must bear a pseudonym, and be accompanied by a closed envelope containing the pseudonym and the author's name. Essays submitted will be treated as material offered to the *British Journal for the Philosophy of Science*.

ERRATA. In the article entitled "Food Products from Plants" in *Nature* of May 23, p. 917, paragraph 3, line 3, for "0·069*d*. per lb. of protein, compared with 0·8*d*. per lb. of protein from beef", read "0·069*d*. per gm." and "0·8*d*. per gm.", respectively.

# ENGINEERING IN THE UNIVERSITY OF NOTTINGHAM

## OPENING OF LABORATORY EXTENSIONS

THE original engineering laboratories of University College, Nottingham, as it then was, were completed in 1930, and until 1948, apart from a small extension of drawing-office accommodation, no further expansion was made. In 1930 the number of full-time students was 17, a number which by 1940 had increased to 44, and by 1946 (the date of the Barlow Report) to 128. In 1950 there were approximately two hundred students reading for degrees in engineering; this number was really far in excess of the facilities at the University's disposal, and adequate training was only given by running dual streams of undergraduates in each year. Such conditions could only be tolerated for a short time to meet a national emergency, and a further demand on accommodation was made when, on the University receiving its charter in 1948, it became possible to develop further the research schools in applied science.

The University was faced with the preparation of a long-term scheme for the development of technology, or of putting into operation a smaller scheme which would bring relief with the shortest possible delay. The first scheme would certainly have taken six years to plan and complete, and in this time the intake of applied science students would have had to be reduced. This seemed contrary to the national interest, and so it was decided to proceed with the smaller project which could be completed in a little more than two years, during which time the student numbers could be maintained and active research schools developed. The project has now been completed, the immediate extra accommodation provided by the extensions representing an increase of some 60 per cent; when rooms at present loaned to the Arts Faculty are available, the total increase of accommodation will be 80 per cent, making possible an intake of students at the rate of ninety a year.

The extensions to the laboratories were opened on April 14 by Lord Hives, chairman and joint managing director of Rolls Royce, Ltd. Lord Hives pointed out that, although society to-day is increasingly dependent on the achievements of applied science, too few of the present-day university students in Britain study this vital subject—only a sixth, in fact, of the 72·5 per cent at universities who are in some measure or other assisted financially by the State. That the percentage of technological students is so small is causing both educationists and industrialists much anxiety, and Lord Hives noted with satisfaction that Nottingham anticipated some time ago the increase in the facilities required for training.

In Lord Hives's opinion, the reason for the unsatisfactory state of recruitment is not to be found at the level of the university, but is something much deeper: it is to be found in the schools and in the attitude of mind of a great number of the parents in Britain. Since engineering, even in its fundamentals, is not taught in schools, too often when a boy comes to consider what he should study at the university, or what career to take up straight from school, he knows nothing at first hand of one of his country's greatest possible careers—engineering.

A distinguished careers master, Mr. Howard Ruby, of Dulwich College, put the position very neatly when he wrote recently that even when careers masters are well aware of the good prospects in an industrial career, their problem is to convince parents and boys, for there still survives in the minds of some parents the view that a career in industry is not so respectable as one in the Armed or Civil Services or other professions. Such a point of view is not only out of date but also harmful, and so long as it persists Britain will never have the skilled men that it requires. A unique place in the estimation of the world has been earned for Britain by its craftsmanship, the skill of its engineers and technicians and the ingenuity of its scientists, and it is necessary that young men should come forward in increasing quality and numbers for past triumphs to be maintained and even exceeded. The main lesson to be learnt from the United States is the high position in society given to industry in that country. As one of the recent Anglo-American productivity teams said in its report: "It is because of this social and intellectual prestige attaching to the highest position in industry that many of the best students choose industry for a career". Lord Hives emphasized the fact that in the engineering industry many of the key positions at the very top of the tree are held by trained engineers. In fact, there is no better training for an executive in the industry to-day than to have worked in his time as a skilled engineer. Yet to many people engineering is still something 'messy', something that polite young men ought not to get mixed up in. Technical engineering, on the other hand, can be the most exciting and fascinating way of earning a living, and the chief reason for this is that it can never remain static.

Prof. J. A. Pope, head of the Department of Civil and Mechanical Engineering in Nottingham, thanked the University Grants Committee and members of industry who through their generous support had made the developments possible, and paid tribute to the University surveyor, Mr. J. W. Popplewell, and his staff on achieving a useful and economical design of building; the capital expenditure per student place had been kept very low without any sacrifice of student amenities or teaching efficiency.

# BRITISH GELATINE AND GLUE RESEARCH ASSOCIATION

## RESIDENTIAL CONFERENCE

THE first residential conference of the British Gelatine and Glue Research Association was held at Hulme Hall, University of Manchester, during April 8–11, and the progress made in the first two and a half years of research work was reported. The meeting was well attended, those present including representatives of gelatine and glue manufacturing firms, of firms using these products, and of government laboratories, research associations and university departments.

The Conference Lecture, by Dr. G. R. Tristram (University of St. Andrews), reviewed recent progress

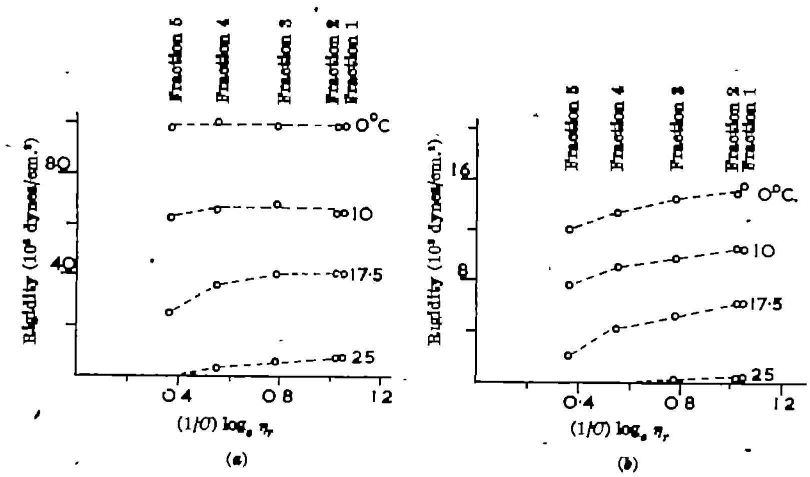

Fig. 1. Rigidity of gels from fractions of gelatin as a function of reduced viscosity ($C = 0·2$ per cent) at temperatures from 0°–25° C. in 1 $M$ sodium chloride at $p$H 7: (a) gel concentration 5·5 per cent; (b) gel concentration 2·2 per cent

in protein research. The techniques by which the amino-acid composition, N-terminal and C-terminal residues, and amino-acid sequence might be determined were given, and illustrated by F. Sanger's work on insulin. Although adequate to give the structure of insulin, which is a protein of comparatively low molecular weight, existing techniques appear inadequate for obtaining the sequence in proteins of higher molecular weight, and still more so for heterodisperse systems such as gelatin.

One of the principal raw materials of the industry was considered by Dr. J. E. Eastoe, in a paper on the composition of bone. The tissue selected for study was a powdered sample of compact bone from the central, tubular portion of the femur of the cow, since it could be obtained almost entirely free of other tissues. The organic components of the tissue were collagen (18·64 per cent), mucopolysaccharide (0·24 per cent), and a protein which resisted solution in boiling water (1·02 per cent). Free sugars were not detected, nor was fat present. Inorganic matter, with which citrate was included, made up 70·91 per cent, and with water (8·18 per cent) gave a total of 99·0 per cent. No significant chemical differences were observed between the bone collagen and hide or sinew collagens. The mucopolysaccharide contained some 70 per cent of a protein of amino-acid composition similar to blood albumin, while the carbohydrate portion did not correspond to published compositions[1] for chondroitin or mucoitin sulphate. Glucos-2-amine, galactos-2-amine, glucuronic acid, galactose and mannose were all detected in the carbohydrate, and they were estimated approximately. The resistant protein was shown to be neither collagen nor elastin.

Mr. D. Fysh gave a short paper describing the equipment being used for empirical studies of the extraction of bone glue. Preliminary results indicate the relative importance of the two stages—heating under steam pressure, and addition of hot water to give the glue liquor—in the extraction process.

The remaining papers were concerned with the properties of gelatin, which had been chosen as the main field of study. Dr. G. Stainsby described a new technique[2] for fractionating gelatin, using the solubility of the complex formed between gelatin and sodium dodecyl sulphate. The method makes extensive use of the work of Smith and Pankhurst[3,4] concerning the behaviour of the complexes. Successive raising of the salt concentration in a solution of gelatin and sodium dodecyl sulphate at 35° C. and $p$H 7 causes portions of the complex to separate as a coacervate. Material of high molecular weight is separated off at the lower salt concentrations. By acetone precipitation, the gelatin present in the coacervate may be separated from the sodium dodecyl sulphate and its properties measured. A very simple procedure involving the preparation of five fractions has proved adequate to show differences in the distribution of molecular weight between closely related gelatins.

P. R. Saunders reported on the properties of the gelatin fractions. Contrary to results obtained by J. D. Ferry for unfractionated materials of differing molecular weight[5], the molecular weight of a gelatin fraction has been shown to be of importance in determining the rigidity of a gelatin gel, only as the temperature approaches the melting point or the concentration is lowered to a point at which weak gels alone are formed. The method used for rigidity measurements[6], involving the deformation of a cylinder of gel, set in a precision-bore tube, under air pressure, was sufficiently simple to enable measurements to be made at two concentrations and four temperatures (0–25° C.) for fractions of six gelatins of widely differing types. The results for one gelatin are shown in Fig. 1. It can be clearly seen that at 0° C. and 10° C. the rigidity (5·5 per cent concentration) was independent of the reduced viscosity ($1/C \log_e \eta_{\text{rel.}}$, in 1 $M$ sodium chloride, $p$H 7) and hence of molecular weight. Confirming results by Pouradier[7], it has been shown that the melting point of gelatin does not depend solely on molecular weight. The viscosity of fairly concentrated solutions has been shown to be uniquely related, within the rather large experimental error, to the dilute solution viscosity.

Dr. A. Courts showed how the fluoro-dinitrobenzene technique of F. Sanger[8] can be used to determine the N-terminal amino-acid residues of gelatin and its degradation products. Typical figures for gelatin prepared from an alkali-treated calf-skin precursor and an acid-process pigskin gelatin are given in Table 1:

TABLE 1

| | N-terminal residues of gelatin (gm./100 kgm. gelatin) | |
|---|---|---|
| | Calfskin | Pigskin acid process |
| Glycine | 0·83 | 0·74 |
| Serine | 0·19 | 0·10 |
| Threonine | 0·11 | 0·08 |
| Alanine | 0·11 | 0·24 |
| Aspartic acid | 0·11 | 0·13 |
| Glutamic acid | 0·10 | 0·07 |
| Others | 0·12 | 0·19 |
| Total | 1·57 | 1·55 |
| Isoelectric point ($p$H) | 5·1 | 9·4 |

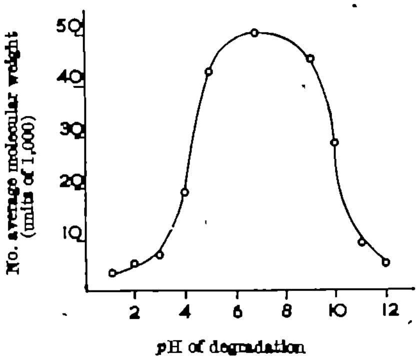

Fig. 2. $M_n$ of gelatin ($M_n$ initial = 58,000) after heating in solution for 24 hr. at 75° C.

The examples quoted in Table 1 were selected to give almost the same total of end-groups, to assist in comparison.

The number of N-terminal residues may be used to give the number-average molecular weight ($M_n$) for the gelatin sample, if it is assumed that the gelatin molecule is a single polypeptide chain with one N-terminal residue per molecule. The values of $M_n$ obtained for alkali-processed gelatins were 50,000–70,000, which is in fair agreement with osmotic determinations by Pouradier[7] for similar gelatins.

A number of samples of a gelatin, which gave $M_n$ = 58,000 by fluoro-dinitro benzene technique, were degraded at 75° C. for 24 hr. at 5 per cent concentration at different pH's. The effect on the values of $M_n$ is shown in Fig. 2. The curve is nearly symmetrical about pH 7. Further experiments at different temperatures suggest a figure of 19,000 cal. for the mean activation energy for breaking peptide bonds, as measured by the release of N-terminal residues. This figure is in quite good agreement with values deduced[9] from the viscosity and other properties.

A. W. Kenchington presented a paper on the methylation of gelatin, and on the means by which the degree of substitution can be estimated when gelatin is modified by organic reactions. The most important method, giving values for several groups, makes use of the titration curve. Provided the isoelectric point is also known, the titration curve can be used for giving values for carboxyl, imidazole, ε-amino and guanidino groups. The proportion of the dicarboxylic acids in the amide form can also be deduced. By analysis of the curves obtained for gelatin samples, the limits of titration suggested by Cannan[10] have been modified, so that at 40° C. they are:

TABLE 2

| | New values | Cannan's values |
|---|---|---|
| Carboxyl groups | pH 1·5–6·5 | pH 1·5–6·0 |
| α-Amino and imidazole | pH 6·5–8 | pH 6·0–8·5 |
| ε-Amino | pH 8–12 | pH 8·5–12·5 |
| Guanidino | not titrated | pK presumed > 12 |

The use of these limits secures agreement between figures for the grouping by analytical and titration-curve methods. The need for the changes results from the following: (i) the presence of a substantial proportion of hydroxylysine; (ii) the higher temperature of measurement reduces the pK of the ε-amino group; (iii) some proportion of the carboxyl groups have pK's in the region of pH 5, and their contribution will only become small above pH 6·5.

Methylation has been carried out by a slow reaction with methanol under acid conditions. Although almost complete methylation of carboxyl groups was achieved, a proportion of the esterified groups is very unstable, and readily loses methanol. Up to 33 per cent substitution, the derivative appears stable to most conditions, but not to alkalis. The degree of substitution was measured using a modified Zeisel method, and the values agreed well with the number of carboxyl groups no longer titratable in the titration-curve method. This suggests that no methylation of hydroxyl groups has taken place. There was also no evidence of methylation of the ε-amino groups. The methylated gelatin was not very different in general behaviour from its parent gelatin and gels were easily obtained. Some degradation had occurred, probably due to the low reaction pH.

E. Courtman outlined a method for determining total bacterial counts for gelatine. Wide variations of total count are known to occur for samples withdrawn from a single gelatine batch[11,12], which result, it would appear, from high local concentrations of bacteria in individual grains. The expression of results as a mean with limits of error will assist in preventing needless disputes over disagreeing values.

M. E. Adams reviewed the manifold uses of gelatine and glue. By classification according to relevant properties, she was able to show that problems of the interface represent the largest gap in knowledge of gelatine and glue.

A. G. Ward, director of research of the Association, in the concluding paper of the conference, outlined the present knowledge of gelatin and its preparation from collagen. The structural features of gelatin which determine the properties of its solutions and gels appear to be, in the main, charge distribution arising from the ionizable groups, molecular weight and molecular weight distribution, and some third factor which affects the rigidity of gels, particularly at low temperatures. This third factor also appears to influence the melting point and the point at which alcohol gives turbidity to a gelatin solution[7]. Little is known of the changes involved in converting collagen to gelatin, but the techniques now available will assist in studying this problem. In addition to these subjects, the Association will in the next five years use empirical methods both for problems of manufacture and for user problems, and also examine in a more fundamental way the behaviour of gelatin at the liquid–gas, liquid–liquid and liquid–solid interfaces. This behaviour is of importance in many uses of gelatine and glue.

# CROP PROTECTION

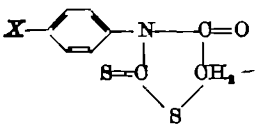
## SYMPOSIUM IN GHENT

THE annual symposia on crop protection, held at the College of Agriculture, Ghent, have attracted larger numbers each year since the present rector of the College, Prof. J. Van den Brande, organized the first meeting in 1948, and at the meeting this year, held on May 5, some two hundred and fifty persons participated. Although the majority were from Belgium and Holland, representatives from several other countries were present. The opening address by Prof. Van den Brande in the morning was followed by two simultaneous sessions for the reading of papers, and during the afternoon a further five papers were read.

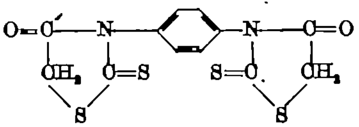
Dr. J. G. ten Houten (Wageningen) gave an excellent general survey of the research now proceeding in the Netherlands on plant diseases and pests and their control. In the work on apple scab, the correlation between temperature and duration of wetting of apple leaves in relation to the primary infection and incubation periods for *Venturia inaequalis*, as established by Mills in the United States, has been confirmed under the climatic conditions prevailing in the Netherlands. By spraying eradicant fungicides (organo mercury compounds) up to five days after infection took place, it was possible to control apple scab by only three sprayings against the six required with protective fungicides like lime sulphur. Spraying with organo mercury compounds, however, can only be used on non-susceptible apple varieties, and such treatments should not be made after ascospore discharge has ceased. Research on the Rubus stunt virus of raspberries has shown that diseased shoots can be completely freed from the virus by immersion in water at 45° C. for 1–3 hours. Excellent control of the pea moth (*Enarmonia nigricana*) attacking canning and other peas which are harvested early has been consistently obtained by one application of parathion when the lower pods are about three-quarters grown. Toxicological trials indicate little consumer hazard if the recommended procedure is adopted. The potato root eelworm (*Heterodera rostochiensis*) is a serious pest in Holland, and to grow potatoes in infested soils or to take a potato crop more than once every three years from non-infested soil is prohibited by law. A team of research workers is concerned with the control of this pest. The investigations include soil treatment with chemicals, finding the substances in potato root extracts responsible for the hatching of the cysts, the possibility of using parasites (fungi and a newly found amoeba), and breeding resistant potato varieties. The control of cyst-forming eelworms with 'DD mixture' was the subject of a paper by Dr. J. Th. W. Montagne (Amsterdam), in which he said that soil treatment with the chemical combined with a short crop-rotation has been found to give the best results. Prof. Van den Brande, R. H. Kips and J. D'Herde (Ghent), also studying the eelworm problem, described how they had examined some of the newer systemic insecticides for nematocidal action. Again, Dr. M. Oostenbrink and Dr. A. F. H. Besemer (Wageningen) showed that a root rot disease in chrysanthemums, pyrethrums and other flowers grown for cutting is associated with parasitic eelworms. Large numbers of *Meloidogyne* sp. and *Pratylenchus* sp. were present in the sick fields, and it had been shown that attack by these pests was a primary cause of the disease, the fungus attack probably leading to the final collapse of the root. Soil fumigation with chloropicrin gave the most effective control.

Several papers were concerned with weed control. M. Slaats and J. Stryckers (Ghent) showed that under certain conditions ammonium dinitro-*o*-cresylate can be used for controlling weeds in hybrid maize; hormone-type weed killers damage the crop. Dr. F. H. Feekes (Baarn) discussed his work on the use of *iso*propyl-N-phenyl carbamate and sodium *iso*propylxanthate as selective weed killers. A striking control of chickweed (*Stellaria media*) was achieved with the former substance at 10 lb. an acre.

Dr. G. J. M. Van der Kerk (Utrecht) described a new group of organic fungicides which has arisen from his work on dithiocarbamic acid derivatives. These compounds are the N-phenylrhodanines with *para* substituents in the benzene ring (I). The most active compound so far obtained is *p*-phenylene-*bis*rhodanine (II), which, against the four fungi tested, is at least as fungicidal as the most active of the dithiocarbamic acid derivatives now used in crop protection.



I



II

Another paper concerned with fungicides was presented by L. Bravenboer (Naaldwijk), who discussed his attempts to correlate the degree of control of *Cladosporium cucumerinum* obtained in practice with the results of laboratory experiments. Prof. R. L. Wain (London) reviewed the present position of systemic fungicides; he gave an account of the more recent British and American work in this field and described the investigations being carried out in his department with aryloxyalkylcarboxylic acids and other compounds. M. J. Zwijns (Maarssen), in discussing seed disinfectants, said that tetramethylthiuram disulphide has given excellent results as a seed dressing for beets, beans, peas, corn, flax and other crops; 2 : 3-dichloro-1 : 4-naphthoquinone and tetrachloro-1 : 4-benzoquinone have also proved satisfactory. R. Bovigne *et al.* (Gembloux) outlined the results of experiments using tetrachloronitrobenzene, methylnaphthyl ethyl ether, methyl α-naphthylacetate and *iso*propyl-N-phenyl carbamate for preventing the sprouting of potatoes. Dr. H. Franke-Grosmann (Reinbek-Hamburg) gave an interesting account of how the gall mite *Aceria gemmarum* (Nalepa) became a serious pest on willow following the use of DDT and BHC against leaf-eating beetles and weevils (*Phyllodecta vulgatissima* and *Pselaphorhynchites* spp.); much damage was caused in *Salix viminalis f. regalia*, whereas *S. americana* was attacked to a much less extent.

Other topics discussed were the value of the Fischer index as a means of estimating the keeping qualities of suspensions (P. H. Martens and J. Henriet, of Gembloux), the control of the cabbage seed-pod weevil with BHC and parathion (Prof. J. H. Schuurmans-Stekhoven, of Deventer), experience in the Netherlands with new types of acaricides

(A. F. H. Besemer and K. Hartsuyker, of Wageningen), a new method of applying pest control materials to plants (Prof. P. Froeschel, of Ghent) and a biological method for assessing residual parathion on cabbage leaves (Dr. J. J. Fransen, of Arnhem).

The organizers are to be congratulated on the satisfactory arrangement and smooth running of this successful symposium. R. L. WAIN

# RESEARCH IN RURAL ELECTRIFICATION

## WORK AT THE ELECTRICAL RESEARCH ASSOCIATION

AN open week, beginning on May 4, was held at the Field Station at Shinfield, near Reading, of the Electrical Research Association, and Mr. G. R. H. Nugent, parliamentary secretary of the Ministry of Agriculture and Fisheries, a Ministry which makes a substantial contribution to the work of the Association, officially inaugurated the proceedings.

The Electrical Research Association established its Rural Electrification Section in 1938 with the main object of developing equipment and operating techniques which are satisfactory to the farmer or grower and which, at the same time, present load characteristics favourable to the economic supply of electricity. The larger the energy taken by rural consumers, especially during off-peak periods, and the lower the power demand, the greater the possible economy. Mr. Nugent emphasized the benefit of electricity on the farm, especially in saving labour and thus increasing production with the present labour force, and also in providing amenities for farm workers to encourage them to stay on the land rather than to succumb to the attractions of the town. A large, and rapidly increasing, number of farms now have electricity, but too many of them fail to make full use of it. Although electric light and domestic power are certainly valuable, much fuller advantage should be taken of electrical methods in agriculture and horticulture. The Ministry, said Mr. Nugent, is fully in agreement with the aims of the research work at Shinfield; economic considerations are rightly kept to the fore in the development of new applications of electricity on the farm.

At the Field Station, basic research determines the form of equipment and the technique required for electrical operation. This is followed by full-scale tests and later by trials under practical conditions on farms and horticultural holdings in different parts of Britain. The co-operation of the agricultural research establishments and of farmers and growers is an essential feature of work of this kind, and the Association has been fortunate in obtaining such co-operation both from its neighbours—the University of Reading and the National Institute for Research in Dairying—and from others much farther afield.

The underlying principle in many of the investigations is simplicity of operation, with electrical methods involving low kilowatt loadings which can be used for a lengthy period. These are much more welcome to electricity supply than the high short-period loads which present difficult problems in rural electrification.

A number of researches already completed have formed the basis for equipment which is now commercially available. Among these are: barn hay-drying, a method of producing very high quality hay by blowing cold, or slightly warmed, air through grass stacked in the barn; a low-powered automatic hammer mill for farm grinding; a soil sterilizer of the immersion type for potting soil; and soil warming in frames and glass-houses by a simplified method in which a daily 'dose' of energy provides beneficial soil warmth but avoids the large consumption needed to maintain a suitable fixed temperature. Work now in progress on the horticultural plots aims at further improvement of the soil-warming technique and at finding the crops and varieties for which it is most likely to be economical in frames, under cloches and in open ground.

In the glass-houses, electric space-heating is used in combination with soil-warming, and different arrangements and forms of construction are being studied to reduce heat losses and so to minimize operating costs. Artificial illumination, using various kinds of lamps and of lighting fittings, is being applied to the raising of tomato seedlings. Laboratory work on soil sterilization by the electrode method, in which current is passed directly through the soil, is preliminary to *in situ* sterilization of glass-house soil. A model glass-house in the exhibition was fitted with many devices which may be developed in future for the complete control of all the factors involved in growing plants to perfection. Presuming that the plant physiologists achieve their goal, this is the ultimate object of the researches now in progress.

Laboratory work on the agricultural side is concerned with the requirements for drying many kinds of agricultural materials and with their equilibrium moisture content in different atmospheric conditions. Grain drying, grass drying and seed drying are studied experimentally, and a novel form of moisture-meter for grain has been developed. A 'farm of the future' in the display showed many new agricultural applications of electricity which, in combination with existing ones, could be used to provide an approximately constant load throughout the year. They would both save labour and give a high load-factor on the farm.

An electrically driven tractor which has been used for the cultivation work at the Field Station during the past three years has the advantages of simple and quiet operation, low running and maintenance costs, and ample tractive effort over a wide range of speeds.

In conjunction with the University of Reading poultry farm, investigations are being made on the possibilities of electrical methods in poultry husbandry. These include air-conditioning for laying hens, the effect of environment on the growth of chicks, and flash illumination in laying-houses as an energy-saving alternative to the usual artificially extended daylight. The destruction of pests by the use of high-frequency fields, the killing of weeds by an electrical discharge and fish-stunning by passing a current through the water in streams or in the sea, are other subjects studied. An experimental heat pump is used for heating one of the laboratory buildings, and its performance is being tested by comparison with that of a conventional plant in another building with similar thermal characteristics. The heat-pump principle is also being applied to dairy work with the object of using heat removed from milk in cooling it to heat water for washing.

Another display showed something of the researches of the Association on the possibilities of wind-power for electricity generation on different scales of use. A survey, for which several new measuring instruments have been developed, is in progress in western coastal areas of Great Britain and Ireland. Many specially favourable sites have been found, and pilot plants, of 100-kW. capacity, are being built in Orkney and for another site. The performance will be tested as a guide to the design of larger machines for which a basis has already been formed by comprehensive design and costing studies. At the same time, the study includes the design, development and use of smaller plants adapted to typical isolated communities in Britain and abroad where adequate alternative sources of power are difficult to come by. For topical interest, the actual record was displayed of the highest wind-speed yet recorded in the British Isles, namely, 125 m.p.h. on Costa Hill, Orkney, early this year.

---

# LATTICE DEFECTS AND THE ELECTRICAL RESISTIVITY OF METALS

An informal conference arranged by the Department of Metallurgy, University of Birmingham, and concerned with recent work on the influences of deformation and irradiation on the electrical properties of metals, was held in Birmingham during April 24–25.

Following an introductory survey by T. Broom (Birmingham), which served to enumerate some present-day problems, J. A. Manintveld (Delft) presented new results for the recovery of resistivity of pure metals after heavy deformation at low temperatures. There is general agreement that a well-defined recovery process occurring at around 0° C. is due to the movement of single vacancies; but a satisfactory account of recovery at lower temperatures is lacking. Prof. M. J. Druyvesteyn (Delft) discussed possible processes for this and also gave results of an investigation into recovery of mechanical properties of polycrystalline wires after low-temperature deformation.

Various mechanisms for the generation of vacancies and interstitial ions during deformation were critically reviewed by Prof. N. F. Mott (Bristol), and one of these, the intersection of screw dislocations, was used by H. G. van Bueren (Eindhoven) as a basis for a theoretical treatment of resistivity-extension curves in which a three-halves power law is obeyed. P. Jongenburger (Eindhoven) completed the discussion of vacancy effects in pure metals by describing his calculations of scattering due to single vacancies in copper, silver and gold.

A new theoretical treatment by S. C. Hunter and Dr. F. R. N. Nabarro (Birmingham) of the resistance due to screw and edge dislocations in metals was presented and the need for a calculation of scattering from stacking faults was pointed out. Predictions of anisotropic scattering from single dislocations formed the basis of an account given by C. W. Berghout (Delft) of some experiments on the anisotropy of resistivity of plastically stretched foils. J. F. Nicholas (Melbourne) gave results of an investigation into the validity of Matthiessen's rule for cold-worked metals and alloys and put forward a qualitative interpretation of the small deviations found.

Resistance changes due to the irradiation of pure metals and the ordered alloy $Cu_3Au$ by electrons, neutrons, deuterons, etc., were discussed by R. A. Dugdale (Harwell). As in deformation studies, recovery experiments reveal effects almost certainly due to the diffusion of vacancies, and indeed recent work at Harwell on $Cu_3Au$ has shown very similar activation energies for recovery of resistivity measured after irradiation, after quenching and after cold-working.

Dr. K. Lücke (Göttingen) reviewed the influence of impurities in copper on the results of deformation and recovery experiments and also gave an account of work on resistance changes in iron due to strain-ageing. Two contributed papers dealt with resistance changes in alloys: Dr. W. H. Aarts and R. K. Jarvis (Johannesburg) reported increases of resistivity during room-temperature annealing of some silver–gold alloys following deformation at low temperatures; Dr. J. O. Linde (Stockholm) wrote giving the results of a study of the effect of deformation on the resistivity of certain binary, ternary and quaternary alloys of silver and gold with transition metals. Finally, J. F. Nicholas (Melbourne) pointed out the lack of any direct experimental or theoretical evidence for the supposition that large resistivity changes caused by the deformation of some alloys are due to the destruction of short-range order.

Many interesting points were raised in discussion and served to reveal the utility of resistivity studies as a means of investigating the structure of metals.

T. Broom

# CROSSED AMORPHOUS AND CRYSTALLINE CHAIN ORIENTATION IN POLYTHENE FILM

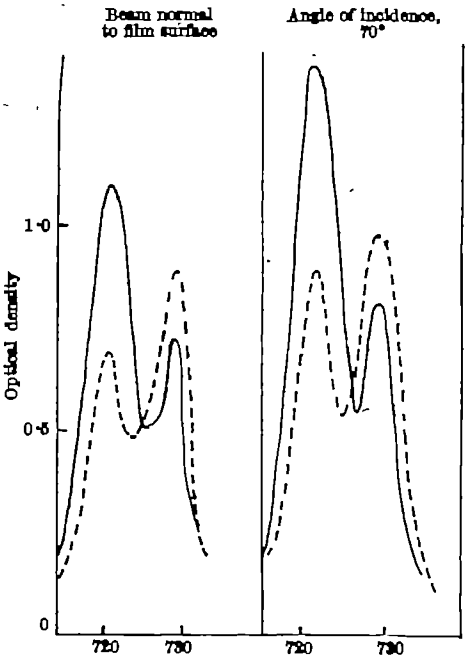
By D. R. HOLMES, R. G. MILLER, R. P. PALMER and C. W. BUNN

Plastics Division, Imperial Chemical Industries, Ltd., Welwyn Garden City, Herts

The structure of polythene film has been investigated by X-ray, optical and polarized infra-red methods. It was found that the polymer chains are oriented differently in the crystalline and the amorphous regions, the respective chain axes being perpendicular to each other. We are unaware of any previous investigations into the orientation in both crystalline and amorphous regions, and as a result this remarkable phenomenon has escaped notice.

Most polythene film is produced by extruding the viscous molten polymer through a slit, passing the resulting sheet downwards into a water quenching-bath, under an idler roller and finally on to a wind-up roller. The whole system is very nearly tensionless to prevent drawing of the film; nevertheless, the films produced do possess some orientation.

The samples available varied in thickness from 0·04 mm. to 0·11 mm. and proved to be of convenient thickness for all three experimental methods, and so no preparatory techniques which might have affected the molecular structure of the film were necessary.



——, Electric vector perpendicular; ----, electric vector parallel to the machine direction

The preferred orientation in the crystalline regions was deduced in the usual way from X-ray diffraction photographs of the film set up in various positions on the goniometer head. The indexing of the photographs and the subsequent interpretation of the results was carried out with the aid of the crystal structure proposed by Bunn[1]. It was found that the *a*-axes of the orthorhombic crystallites tend to lie parallel to the machine direction in the film (that is, the direction of travel of the film during production). The *b*- and *c*-axes are randomly oriented in a plane perpendicular to this direction.

Microscopic observation of the films in plane polarized light showed that all the films are optically biaxial and that the machine direction generally has the highest refractive index. Birefringence measurements on tilted specimens and on sections cut perpendicular to the machine direction and also observations of interference figures established the orientation of the optical indicatrix. With the usual nomenclature, $\gamma$ lies along the machine direction, $\beta$ is perpendicular to the machine direction in the plane of the film and $\alpha$ is perpendicular to both the machine direction and the plane of the film. $(\gamma - \beta)$ is about ten times as great as $(\beta - \alpha)$ and varies from $-11$ to $+41 \times 10^{-4}$ for the films examined.

Calculations of the principal refractive indices of the polythene molecule and crystal separately (from bond polarizabilities and the Lorenz–Lorentz equation)[2] showed that in both cases $\gamma_{AC}$ is parallel to the chain axis; the suffixes $A$ and $C$ refer to the amorphous molecule and the crystal respectively. For the molecule, $\beta_A$ is parallel to the plane of the carbon atoms but perpendicular to the chain axis, and $\alpha_A$ is perpendicular to both the plane of the carbon atoms and the chain axis. For the crystal, $\beta_C$ lies along the *b*-axis and $\alpha_C$ along the *a*-axis. The optical evidence, together with the X-ray evidence that the chain (*c*-) axes of the crystallites are perpendicular to the machine direction, indicated that there must be considerable orientation of the amorphous molecules with the direction of their chain axes parallel to the machine direction.

Confirmatory evidence was obtained by the use of infra-red absorption measurements on the doublet band which occurs in the polythene spectrum at 721 and 729 cm.$^{-1}$. This has been ascribed by Sheppard and Sutherland[3] to a rocking motion of the methylene groups, and Elliott *et al.*[4] and Rugg *et al.*[5] have shown that in fully drawn polythene both parts of the band exhibit perpendicular dichroism. Therefore, we deduce that the transition moment causing this absorption is perpendicular to the carbon chain and parallel to a line joining the hydrogen atoms of a methylene group. The direction of this transition moment lies in the *ab* plane of the polythene crystal and makes an angle of 41° with the *a*-axis[1]. The component parallel to the *a*-axis is greater than that parallel to the *b*-axis and there is no component along the *c*-axis.

When polythene is melted, the peak at 729 cm.$^{-1}$ disappears and is therefore ascribed to the crystalline regions of polythene. The second peak, at 721 cm.$^{-1}$, although probably due in part to the crystalline material, is mainly due to the rocking vibration of the methylene groups in the amorphous regions. Consequently it is possible to obtain some measure of the orientation in crystalline and amorphous regions separately.

Observations were made using polarized infra-red radiation with the electric vector parallel and perpendicular to the machine direction. With the beam normal to the film, the 'amorphous' band at 721 cm.$^{-1}$ showed perpendicular dichroism (that is, there was greater absorption of the light with the electric vector vibrating perpendicular to the machine

DETAILS OF RESULTS OF X-RAY, OPTICAL AND INFRA-RED EXAMINATION OF POLYTHENE FILMS

direction); but the 'crystalline' band at 729 cm.$^{-1}$ exhibited parallel dichroism. When the film was rotated about the machine direction as axis to angles of incidence of 30°, 45°, 60° and 70°, the dichroism remained the same for the crystalline band at 729 cm.$^{-1}$, but the perpendicular dichroism of the absorption band at 721 cm.$^{-1}$ decreased slightly as the angle of incidence increased (see graph). These results on the band at 729 cm.$^{-1}$ indicated that the crystals are oriented with their $c$-axes perpendicular to the machine direction and probably with their $a$-axes parallel to it.

The observations on the band at 721 cm.$^{-1}$ showed that in the amorphous regions the orientation was different from that in the crystalline regions, and that the plane of the carbon chain contained the machine direction. However, the optical evidence shows that the axis of the carbon chain is parallel to the machine direction, and with this established the infra-red dichroism indicates that there is a slight preference for the plane of the carbon atoms to be perpendicular to the plane of the film. In view of this preference, the optical result that β was parallel to the plane of the film indicated a slight preference for the $c$-axes of the crystallites to lie in the plane of the film. Details of the results on fifteen different samples of film are shown in the accompanying table. It should be noticed that samples showing good amorphous orientation generally possess good crystalline orientation in a perpendicular direction.

A consideration of the manufacturing process helps towards an understanding of the formation of such an unusual structure. The extrusion through the slit followed by the downward flow into the quenching-bath produces good alignment of the polymer chains parallel to the machine direction, ready for crystallization to occur as soon as the film reaches the quench-bath. The water quenching-bath is often nearly boiling and therefore relaxation takes place simultaneously with crystallization. Nancarrow and Horsley[6] and also Brown[7] have found that, when relaxation of stretched polythene monofilaments occurs, the crystallites tend to take up a position with their $a$-axes parallel to the original direction of stretch. Our observations show that a similar orientation occurs in the relaxation of polythene film. Many attempts[4,8] have been made to explain the orientations occurring during the stretching and relaxing of polymers in terms of preferred cleavage and slip planes and also from a thermodynamic point of view, but none has been completely satisfactory. It is probable that the preferred directions of crystal growth are equally important in the present case where crystallization and relaxation are occurring simultaneously.

The amorphous regions of the film are formed of those polymer molecules which have an unfavourable spatial configuration for crystallization and necessarily show good orientation with their long axes in the machine direction. No explanation can be advanced at present for the slight amount of amorphous double orientation observed.

# CARBON DIOXIDE CONCENTRATION AND MAXIMUM QUANTUM YIELD IN PHOTOSYNTHESIS

By Prof. E. STEEMANN NIELSEN

Royal Danish School of Pharmacy, Copenhagen

FOR fifteen years controversy has occurred about the maximum quantum yield in photosynthesis. Whereas one molecule of carbon dioxide is reduced by 3–4 quanta according to Otto Warburg and co-workers, at least 8 quanta are necessary according to Emerson and his school. Rabinowitch[1] has given a thorough review of the whole literature.

Warburg and co-workers[2,3] have, however, published the results of new experiments intended to explain why Emerson and his school have never been able to find a quantum yield higher than about 1/8. According to ref. 2, a carbon dioxide concentration of 5 per cent per volume is necessary both in an acid and in an alkaline medium in order to produce the maximum yield in *Chlorella pyrenoidosa*. Emerson's school used an alkaline medium (Warburg buffer No. 9), the carbon dioxide concentration of which is 0·2 per cent.

The optimum rate of photosynthesis at high light intensities in *Chlorella pyrenoidosa* is found both in an alkaline and in an acid medium already at very low concentrations of carbon dioxide (0·08 per cent according to Whittingham[4]). According to all reliable investigations[5], curves for different light intensities showing the dependence of the photosynthetic rate on carbon dioxide concentration at low concentrations merge into a single straight line. At low light intensities where the quantum yield is to be measured, saturation is achieved at lower concentrations rather than at high intensities.

The claim of Warburg that the optimum rate of photosynthesis at very low light intensities should need a concentration of carbon dioxide about two hundred times as high as the concentration necessary at high intensities thus seems erroneous. Experiments were therefore carried out with Warburg's strain of *Chlorella* in order to investigate the background of his statement. Both the rate of photosynthesis and the rate of respiration were measured by the Winkler method (oxygen metabolism). Fluorescent light was

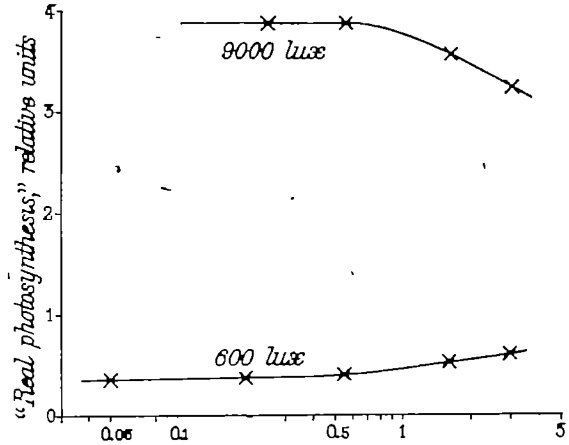

Fig. 1

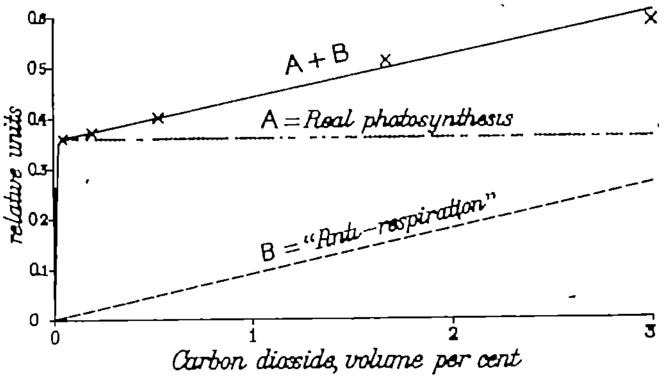

Fig. 2

employed. The maximum intensity was 9,000 lux. Lower intensities were obtained by using neutral filters. The experiments lasted 90–240 minutes.

The upper curve in Fig. 1 gives a typical example of a series of experiments at a high light intensity (pH 6·8, 21° C.). The different concentrations of carbon dioxide were made by mixing a solution of potassium bicarbonate with water saturated with carbon dioxide and water free of carbon dioxide. The concentration varied from 0·25 to 3·0 per cent. The lowest two concentrations were on the saturation plateau. Concentrations above 1 per cent, however, are too high for optimum photosynthesis. The rate at 3 per cent had decreased by 16 per cent.

In the lower curve in Fig. 2 the result of experiments made simultaneously at 600 lux is plotted. The shape of the curve differs definitely from the shape of the upper curve. From a concentration of about 0·3 per cent the curve unmistakably starts ascending. The rate of photosynthesis apparently increases by 50 per cent by increasing the carbon dioxide concentration from 0·5 to 3·0 per cent. This is nearly the same as shown by Warburg et al.[3].

The shape of the complete lower curve in Fig. 1, however, clearly indicates that this curve does not solely represent the dependence of photosynthesis on carbon dioxide concentration.

Kok[6] has shown that the light curve in photosynthesis undergoes a sudden change of slope somewhere near the compensation point. He presumes that dark respiration upon illumination is completely suppressed and substituted by another mechanism. A concentration of carbon dioxide of 5 per cent was employed. In later investigations[7] a concentration of only 0·2 per cent was employed. Although the temperature was increased to nearly 30° C. in order to bring about the break in the curve, only a slight break was found.

The only other investigator demonstrating the change of slope of the light curve in the neighbourhood of the compensation point is Van der Veen[8], who made his experiments with tobacco leaves in air with a carbon dioxide concentration of 3·6 per cent. In ordinary air (0·03 per cent carbon dioxide) a significant break has never been observed in leaves.

Variations of the carbon dioxide concentration have no influence on the rate of respiration of *Chlorella* in the dark. The rate was the same at 0·4, 1·2 and 5 per cent. The following survey is therefore presented concerning 'anti-respiration' in light, explaining at the same time the shape of the lower curve in Fig. 1.

(1) At low carbon dioxide concentrations light respiration corresponds to dark respiration.

(2) The part of the respiration located in the chloroplasts is apparently blocked up by high concentrations of carbon dioxide when at the same time a sufficient rate of photosynthesis is going on.

(3) Phosphates rich in energy produced during photosynthesis either reduce the respiratory intermediates back to the carbohydrate level or respiration is simply stopped due to the blocking up of the respiratory system. In Fig. 2 the lower curve shown in Fig. 1 is analysed according to this classification.

A third—possibly as likely—explanation is that normal photosynthesis is replaced by a photochemical reduction of intermediate respiration products (cf. Franck[9]).

Warburg et al.[10] have published experiments according to which the oxygen uptake by a *Chlorella* suspension in light was exactly the same as in the dark. They therefore rejected all hypotheses which postulate an interrelation between photosynthesis and respiration. As they, however, worked under conditions of complete absence of carbon dioxide, their argument does not concern the present theory.

Instead of computing the quantum yield from the slope of the light curves, Warburg and co-workers have confined themselves to measurements at a single light intensity. They first compensated for respiration by using white light, and then, by adding a definite amount of light energy, they measured the increase in rate of oxygen production or carbon dioxide uptake. Warburg et al.[3] mention that the absorbed light intensity must be small if a maximum yield is to be obtained. In fact, they used extraordinarily small light intensities. The intensity used for measuring quantum yield is normally at most about a third of the intensity necessary for reaching the compensation point. Linearity of light curves of *Chlorella*—apart from the break in Kok's curves—is found up to light intensities at least 3–4 times the intensity necessary for compensation of respiration.

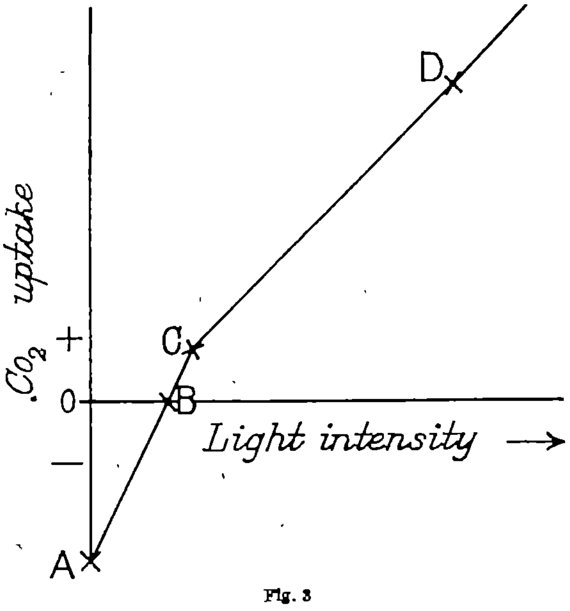

Fig. 3

In dense cell suspensions where light intensity varies considerably from cell to cell, 'anti-respiration' must be supposed to increase far above the compensation point. In Warburg's experiments a light absorption in the red part of the spectrum of about 2/3 was found. Fig. 3 gives a schematic light curve of *Chlorella* at a high concentration of carbon dioxide. *A C* is that part of the curve where 'anti-respiration' increases with increasing light intensity, *C D* is that part where 'anti-respiration' is constant and where the quantum yield is to be measured, *B C* that part where Warburg measured the quantum yield. It is not, therefore, surprising that this 'yield' is about double the size of the real one.

Efforts were made to measure 'anti-respiration' by using carbon-14. There are, however, too many complications if rate of photosynthesis and rate of respiration are to be measured separately by means of tracer carbon. The final report will appear in *Physiologia Plantarum*. [Jan. 7.

# SYNOPTIC ROCKET OBSERVATIONS OF THE UPPER ATMOSPHERE

By DR. S. F. SINGER

Office of Naval Research, U.S. Embassy, London

ONE of the main limitations of present-day rocket research in the upper atmosphere is the fact that it is possible to make only a few launchings each year, generally from only one location (at White Sands, New Mexico)[1]. For many important investigations it would be desirable to conduct rocket observations more frequently, even though the payloads and the peak altitudes may not be particularly high. What is needed, then, is a method which combines the following features: (i) a cheap rocket (less than £300); (ii) an inexpensive and easy method of launching; (iii) the possibility of making launchings in any geographical location, for example, over the open sea and over the inaccessible polar regions or desert regions; (iv) the possibility of making a number of launchings within a short time interval, perhaps as short as a few minutes; (v) the possibility of controlling the time of firing to an accuracy of a few seconds in order to correlate it with occurrences observed from the ground; (vi) the possibility of making time-correlated measurements at two or more geographical locations.

An approach to these points, which might offer the first real possibility for synoptic rocket observations, would be provided by launching a small rocket from a high-flying (piloted or pilotless) aircraft. This suggestion arises from the pioneer experiments of Van Allen and collaborators[2], who have devised an inexpensive scheme for transporting some 20 kgm. (40 lb.) of apparatus to altitudes of about 80 km. (270,000 ft.). The essence of their scheme is to mount the apparatus on a small rocket, lift this entire assembly to an altitude of 15 km. (50,000 ft.; that is, above 90 per cent of the atmosphere) with a large polyethylene balloon, then fire the rocket in a near-vertical direction. The same rocket launched from sea-level reaches only about 20 km.; thus by eliminating the aerodynamic resistance of the lower atmosphere, a great increase in the peak altitude of the rocket can be realized. During the summer of 1952, several such launchings were successfully carried out near the geomagnetic pole under the leadership of Lieut. M. S. Jones, of the U.S. Office of Naval Research. The rockets employed were the very small, rapid-burning 'Deacon' rockets using a solid propellant of high specific impulse. The cost per rocket was about £300.

An important advantage of the aircraft-launching method suggested here lies in the elimination of inevitable and uncertain delays, which are inherent in balloon launchings and depend on surface wind conditions, plus the time it takes the balloon to reach altitude. In addition, the aircraft firing does away with the logistic difficulties and expense of transporting helium, balloon launching crew and equipment to the desired launching location. A further consideration is the fact that the actual location of firing, and therefore the probable impact area, can be controlled to much narrower limits than with balloons which are subject to wind conditions; this greatly simplifies the range-safety problem.

The uses to which such an inexpensive research rocket can be put are very wide and likely to be of importance in many investigations on the upper atmosphere. The region from 40 km. up to 80 km. (the position of the temperature minimum and generally taken to be the lower boundary of the ionospheric region) is an interesting one from the point of view of the structure of the atmosphere. Since the small rocket is not stabilized, and since it might not be worth while to install aspect-recording devices such as have been used for larger rockets, a different and perhaps simpler approach will have to be taken in some of the measurements. On the other hand, it would not be difficult to obtain a certain amount of gyroscopic stability by imparting a high angular velocity to a small flywheel with its axis mounted along the rocket axis; this might even be done from the launching plane by means of compressed air or electrically just before the actual firing. Measurements of ambient air pressures in the interesting region will be facilitated by the use of rockets of lower velocities. The technique of exploding grenades at high altitudes to obtain sound velocities, and thereby the temperature distribution[3], could, of course, be adapted easily for studying the latitude, diurnal and seasonal variations of upper air temperatures and winds. Studying the composition of the upper stratosphere would seem especially worth while in view of the recent discovery by Prof. F. A. Paneth's group that gravitational separation of light and heavy gases becomes appreciable at altitudes as low as 70 km.[4]. Air sampling bottles should be very appropriate for this investigation since the time spent between 70 km. and 80 km. is more than 90 sec., as compared with less than 15 sec. for the standard Aerobee rocket in current use. The accuracy to which the time of firing can be controlled, plus the easy accessibility of the rocket until just a few seconds before firing, make very feasible the scheme suggested by Prof. F. E. Simon for collecting a much larger air sample by means of a liquid hydrogen condensation pump[5].

Prof. L. F. Bates has suggested the intriguing possibility of releasing material from a rocket so as to change the concentration of certain rare atmospheric constituents, such as sodium[6]. Even a small increase in the interval 70–80 km. might produce spectacular results in the light emission from the night sky. Again, the long time which the rocket spends in the interesting region may at last make this experiment possible.

Of particular meteorological importance would be regular synoptic measurements of the ozone content in the upper stratosphere using omnidirectional ozone detectors, such as photocells sensitive to the ultra-violet with suitable filters. Actual measurements of the vertical distribution of ozone would provide valuable calibrations of the zenith angle method used in sea-level observations[7]. Thus it would be possible not only to conduct simultaneous measurements at widely different locations of the ozone content and its distribution with altitude, but also to measure rapid changes in a particular location. The relation of such data to tropospheric weather[8] and to upper air temperatures would be of the greatest importance. Measurements in the highest layers of the ozonosphere in relation to solar phenomena would provide a valuable check of photochemical theory[9].

Essential to the understanding of photochemical and ionization reactions in the upper atmosphere[10] are periodical measurements of the solar ultra-violet radiation. They could be carried out without the necessity of sun-pointing and following devices, by using such wide-angle detectors as thermoluminescent crystals[11] or photon counters[12].

Another attractive opportunity for meteorological research arises from the possibility of synoptic high-altitude photography for the study of the distribution of clouds over a large area.

Several ionosphere investigations suggest themselves: for example, the measurement of high-altitude electric current systems in the auroral zone during different geomagnetic and auroral conditions by means of rocket-borne magnetometers[13], and radio propagation experiments to measure ion and electron densities. The low rocket velocity would simplify more direct methods for determining ion densities to check theoretical predictions[14] for this important quantity.

The altitudes reached by this rocket are of special usefulness for certain types of cosmic-ray experiments. For studying the position and extent of the low energy cut-off in the primary radiation[15], it would be desirable to make time-correlated measurements of the total intensity at various geomagnetic latitudes. Another important investigation concerns fluctuations, correlated with solar phenomena, of the extremely soft component of the primary radiation which may enter at very high latitudes, but which is unable to penetrate more than about 1 gm./cm.$^2$ thickness of matter. This soft radiation is thought to be the most sensitive indicator of solar effects of cosmic rays. The short time which the rocket spends above the appreciable atmosphere (above 50 km. for cosmic-ray purposes) constitutes no particular handicap, for omnidirectional detectors giving high counting-rates can be used; a statistical accuracy of one per cent is easily obtainable.

It is clear that the list of possible investigations given above is incomplete. Once this technique of upper air exploration has been put in operation, many other, and possibly more important, investigations will undoubtedly suggest themselves to specialists in various fields.

Compared to ground-launched large rockets, the method suggested here would not only be within the scope of a much more modest research budget, but also would actually make possible studies of physical problems of the atmosphere and studies of extra-terrestrial radiation which are outside the range of, but complementary to, present-day high-altitude rocket experiments. It would, in fact, put rocket research on much the same basis as weather balloon soundings or ionosphere radio soundings.

# GREGARIOUSNESS IN BARNACLES IN RELATION TO THE FOULING OF SHIPS AND TO ANTI-FOULING RESEARCH

By DR. E. W. KNIGHT-JONES and DR. D. J. CRISP

Marine Biology Station, University College of North Wales, Bangor

BECAUSE of their relevance to applied work, we feel it is desirable to direct attention to the results of investigations at this station on the setting behaviour of three species of barnacles, *Balanus balanoides*, *Balanus crenatus* and *Elminius modestus*, as observed in the laboratory. The last two species are important fouling organisms, and it seems likely that the phenomena described below will also be found in other species not yet investigated. Gregarious settlement in *Elminius modestus* has previously been reported as a result of field experiments[1].

Setting is encouraged by gentle water movement which stimulates attachment. After alighting on a suitable surface, the cyprids walk about, pulling themselves forward by each antennule alternately, and changing direction only infrequently. They swim off again much more readily than has hitherto been assumed, and on an unsuitable surface such as glass, or one with loose particles, or at a sharp edge, they may swim off almost at once. If, however, they encounter a barnacle of their own species or even the persistent basis of such an individual, they then rarely swim off, but instead embark on a characteristic setting-action pattern. During this stage, which has been observed by Doochin[2], a cyprid walks more slowly with random changes in direction of increasing frequency, pivoting on one antennule and testing the substratum with the other. After spending about half an hour in the reconnaissance of a small area, stopping and turning in one small depression after another, it normally comes to rest in one of them. Here it moves to and fro, rotates and flicks the posterior cirri vigorously to sweep out any silt or loose particles. It then pulls itself down on its antennules in a direction facing the incident light, or as nearly as is compatible with its fitting snugly into the depression. Contrary to previous belief[3], this final orientation is achieved by a distinct reaction at the time of setting. Slight rolling movements, due to alternate pulling on the antennules, then ensue, and the attachment cement is ejected and spread around the antennulary suckers. Finally, all movements cease until metamorphosis is heralded by renewed activity about twenty hours later in *Balanus balanoides* and *B. crenatus*, and about four hours later in *Elminius modestus*. It is interesting to note that the setting behaviour pattern of barnacles, with a wide initial exploration and a detailed final search after encountering its own species, is remarkably similar to that of oysters[4] and *Spirorbis*[5], providing a good example of convergent evolution.

We have also noted that if cyprids make contact with attached individuals on a surface intrinsically unfavourable for setting (for example, glass, or one crowded with recently settled barnacles) they may swim off again but are then more ready to begin colonizing bare surfaces. This explains the especially rapid fouling of surfaces in the vicinity of shores where adults are abundant[1] and the rather slow initial colonization of new sea-walls[6] and ships newly painted with non-toxic paint. Such craft moored alongside quays heavily barnacled by the appropriate species will tend to be fouled more readily than they would be if moored away from such places, even though cyprids be equally abundant. Moreover, once a ship has been fouled, cleaning by mere scrubbing down will leave behind the bases, and these will stimulate rapid re-colonization.

The property of the cemented bases which stimulates setting is removed only by such powerful reagents as attack quinone-tanned proteins; sodium hypochlorite, for example, dissolves the bases away. Tests carried out on cyprids show that the surface gives a strong argentaffine reaction, local chromaffine staining and a positive response to the diazo and indophenol tests, indicating the presence of a phenolic substrate. These observations afford evidence that the epicuticle of barnacles, like that of other arthropods[7], contains a quinone-tanned protein. The thin epicuticle and the attachment cement have been shown by Thomas[8] to be of the same material and secreted by similar tegumental glands. It is probably this substance which is detected in some way by the crawling cyprid. To remove the bases by chemical means from the bottom of a ship is scarcely practicable, nor is it necessary, for if the bases are covered with new paint, or even by a continuous film of nitrocellulose, they will no longer induce setting.

When testing anti-fouling paints, differences between toxic panels and non-toxic controls are sometimes masked by abnormal variations in numbers of barnacles setting on replicates. This may render any valid comparison difficult, and in any event reduces the precision of the experiment. Such differences now appear to be due, not so much to variation in the numbers of larvæ available for attachment, but rather to the hitherto unsuspected fact that the presence of settled individuals induces others to settle. Hence the rate of settlement will not be uniform, even when the number of cyprids arriving from the plankton is constant. If, for example, each cyprid explores an area $A$, and settles only if it meets a previously settled individual, the rate of increase, $dn/dt$, in the number per unit area, $n$, assumed randomly distributed over the surface, will be $dn/dt = N(1 - \exp - An)$, where $N$ is the number arriving on unit area in unit time. Thus colonization of a bare panel will show an initial time-lag prior to the setting of a pioneer individual, then a logarithmically increasing rate of settlement (while $An \ll 1$), then a steady rate (when $An \gg 1$) equal to $N$, and finally a decreased rate since a crowded surface is repellent. Small time-differences in gaining an initial settlement, since they are followed by a logarithmic increase, will result in wide divergences in numbers on replicate panels, until crowding, by reducing settlement on the more densely populated surfaces, leads to greater uniformity. Results conforming to this sequence have been repeatedly obtained in practice.

It also follows from these observations that a test panel which has gradually lost its toxicity might remain clean for some time if settlement is light, but when the first pioneers become attached, further settlement might take place so rapidly as to suggest sudden loss of toxicity. On the other hand, cyprids persistently attempt to settle on test panels adjoining dense populations of adults. If the paint is not quite lethal, metamorphosis may take place, but the spat readily fall off, presumably because the paint is still able to upset the cementing mechanism. Those that first succeed in cementing themselves permanently may afterwards show deficient basal growth or distorted bases, as previously noted by Weiss[9].

On the basis of these findings, we suggest the following refinements in the testing of anti-fouling paints for effectiveness against barnacles.

(*a*) The test raft should be kept well covered with barnacles.

(*b*) The test surface should, if possible, be contiguous with a heavily barnacled surface.

(*c*) Control panels of two kinds should be employed: (i) quite bare, with a surface similar to the paint surface but non-toxic, to indicate the 'pioneer' attack; (ii) covered with bases of locally abundant species to give the maximum settlement.

(*d*) In comparing the number setting on test panels and non-toxic controls, due allowance should be made for the influence of previously settled individuals on the rate of settlement.

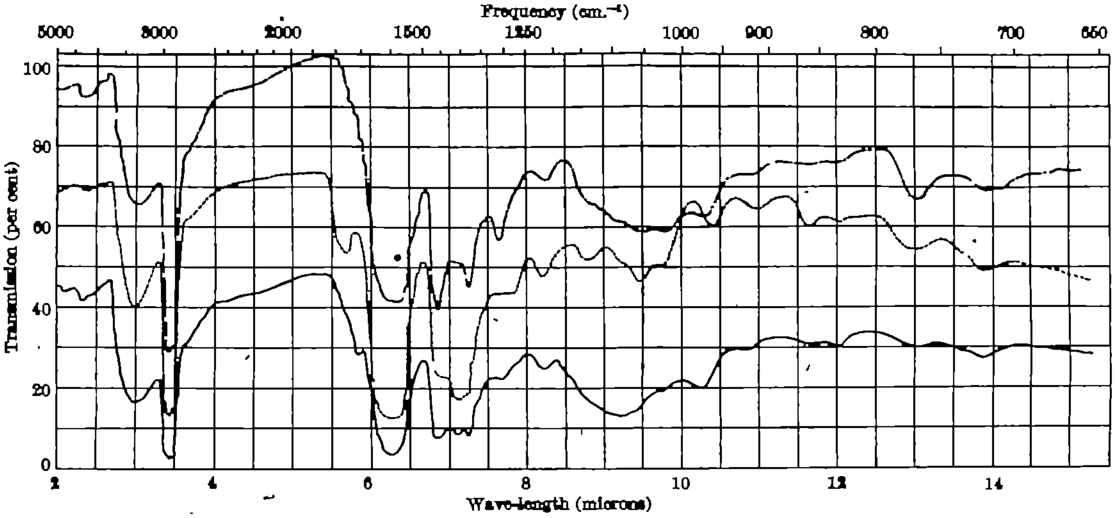
### Fluoroacetate Poisoning: Comparison of Synthetic Fluorocitric Acid with the enzymically synthesized Fluorotricarboxylic Acid

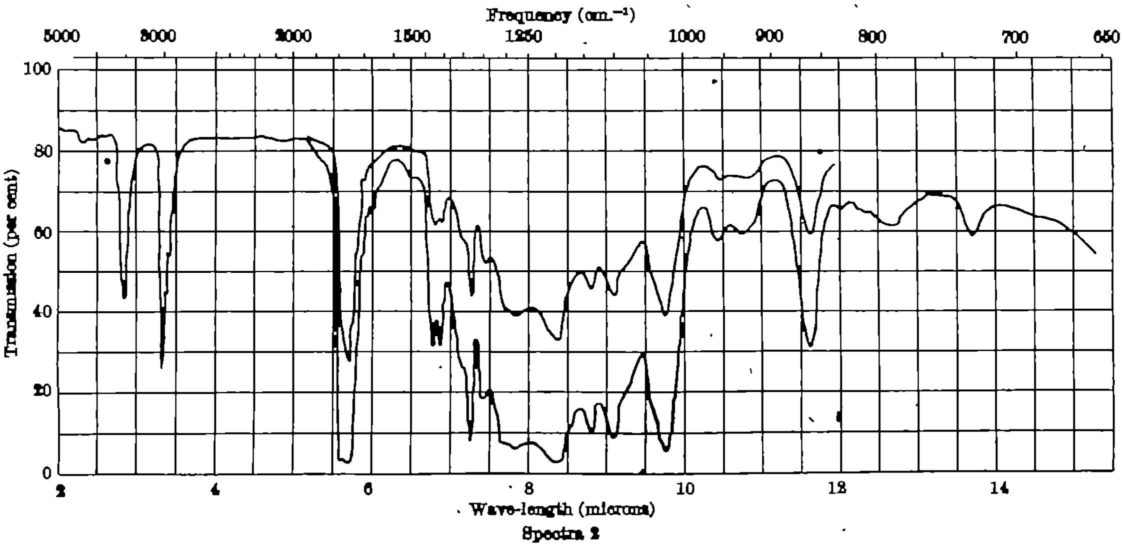
THE hypothesis advanced earlier to account for the toxicity of fluoroacetate ($FCH_2.COONa$) has been proved recently by the isolation of an enzymically synthesized mono-fluorotricarboxylic acid in crystalline form[1], prepared from the products of interaction of kidney tissue with fumarate and fluoroacetate. Though there was much to suggest that it was mono-fluoro*citric* acid, this had not been rigorously proved by a comparison of the infra-red spectrum with a synthetic specimen. The recent synthesis by one of us (D. E. A. R., in the press) of fluorocitric acid has made it possible to compare the infra-red spectra of the barium salts of this with the barium salt from 1·5 mgm. of the enzymically synthesized (natural) crystalline compound isolated in Oxford (by R. A. P. and R. W. W.).

*Infra-red spectra.* The curves obtained from the barium salts are shown in the accompanying spectra; this salt was used as it proved to be the most convenient compound for infra-red study. Though the spectrum of the product of biochemical synthesis differs slightly from the spectrum of barium fluorocitrate, the differences are such as would be caused by the presence of small amounts of barium citrate and barium sulphate as impurities; in the purest specimen (–·–), the citrate present is thought not to be greater than 5 per cent, which explains why it was not detected by the colorimeter tests[1].

These spectra were obtained from 'Nujol' mulls of the barium salts, using a micro technique. The spectrometer used was a double-beam Perkin–Elmer, Model 21.



Spectra 1



Spectra 2

Spectra 1. Comparison of infra-red spectra of barium salt of synthetic fluorocitrate (dotted curve) with the spectra of barium salts of fluorotricarboxylic acid enzymically synthesized from fluoroacetate; ———, first sample showing the band at 9·75 microns; –·–·–·–, highly purified crystalline specimen

Spectra 2. Ethyl fluorocitrate

The spectrum of the sample of ethyl fluorocitrate, from which the barium fluorocitrate was prepared, is also reproduced for reference.

*Activity as inhibitor of citric acid metabolism.* Using the usual test, Peters *et al.*[1] found that 0·61 μgm. of the 'natural' fluorocitrate inhibited the disappearance of 1 μmole citric acid under the conditions of the test made with particle preparations from kidney.

During the course of the work at Porton (by D. E. A. R.), several specimens of synthetic fluorocitric acid have been examined in Oxford, which have not shown more than half the biochemical activity of the 'natural'. The barium salt from the purest synthesized specimen was dissolved in hydrochloric acid and the barium precipitated with sodium sulphate. After removal of barium sulphate, an activity test showed the following for μmoles inhibited: 10 μgm. barium salt inhibited 4·86 μmol. citric acid, from which it can be calculated that 1 unit of inhibitor is equivalent to 1·04 μgm. synthetic fluorocitric acid. Another test gave 1·07 μgm.

Allowing for experimental error, an average of 1·05 μgm. (synthetic) has approximately one-half the biochemical activity of the 'natural', determined as 0·61 μgm. on average (0·58–0·64, ref. 1). As there should be two optically active centres in fluorocitric acid, there should be four stereoisomers; if these are present in equal proportions in the synthetic mixture, then only one optically active centre seems to be important for the activity. Elsewhere, we have reported[2] that the synthetic fluorocitrate has similar convulsive effects in the pigeon brain to those obtained with the enzymic preparation.

*Conclusion.* As the spectra of the enzymically synthesized compound show no bands which cannot be accounted for by the bands seen with the synthetic fluorocitric acid together with bands expected from traces of barium salts, the compound made enzymically must be actually monofluorocitric acid; it has approximately twice the activity of the synthetic specimen.

# A New Application of EDSAC to Crystal Structure Analysis

It is well known that the structure of a centrosymmetric crystal could be solved by selecting a number $N$ of structure factors ($F(\mathbf{h})$'s), and evaluating the electron density

$$\rho(\mathbf{r}) = \frac{1}{V} \sum_{\mathbf{h}} \pm |F(\mathbf{h})| \cos 2\pi \mathbf{h}.\mathbf{r}$$

for each of the $2^N$ possible sign combinations on the $F(\mathbf{h})$'s. The correct choice of signs would give a recognizably correct structure when $N$ was sufficiently large. For crystals of moderate complexity, experience has shown that the structure can be determined after the correct signs of about twenty of the largest structure factors have been found. Even when a very rapid means of evaluating a multi-dimensional Fourier series, such as Pepinsky's X.R.A.C.[1], is available, it is not feasible to evaluate and inspect about $2^{20}$ (more than a million) electron-density maps. Our application of the EDSAC consists effectively in making the machine survey this large number of alternative answers, and select from them a few which fulfil certain criteria. The following is a brief outline of the method.

Not all sign combinations are *a priori* equally probable; but inequality relations between structure factors, for example, generally rule out only a small proportion of them—in the example which we give later, they impose no immediate limitations. On the basis of results obtained by Sayre[2], it may be shown that the extent to which $\chi \equiv \sum\sum_{\mathbf{h}\,\mathbf{h}'} U(\mathbf{h})U(\mathbf{h}')U(\mathbf{h}+\mathbf{h}')$ is positive may be taken as a measure of the 'plausibility' of a particular set of signs, as a positive value of $\chi$ corresponds to positive peaks in the electron-density map. ($U(\mathbf{h}) = \dfrac{F(\mathbf{h})}{F(0)f}$, see Harker and Kasper[3].) The $U$'s involved in this summation are in practice only those of greatest magnitude. We have used salicylic acid[4] as an example. As an approximation, the differences in magnitudes of the largest eighteen $U$'s were ignored, and then $\chi$, apart from a scale factor, is given by making all the $|U|$'s unity. $\chi$ was evaluated for each of $2^{16} = 65{,}536$ independent possibilities. This calculation was completed in less than three hours using the EDSAC. On the scale that we used, possible values of $\chi$ ranged from + 29 to − 29. The number of sign combinations corresponding to each value of $\chi$ is shown in the accompanying table.

| Value of $\chi$ | No. of sign combinations |
|---|---|
| 29 | 0 |
| 27 | 0 |
| 25 | 0 |
| 23 | 0 |
| 21 | 6 |
| 19 | 27 |
| 17 | 79 |
| 15 | 250 |
| 13 | 632 |
| 11 | 1,320 |
| 9 | 2,404 |
| 7 | 3,975 |
| 5 | 6,043 |
| 3 | 8,076 |
| 1 | 9,386 |
| − 1 | 9,644 |
| − 3 | 8,588 |
| − 5 | 6,536 |
| − 7 | 4,356 |
| − 9 | 2,472 |
| − 11 | 1,111 |
| − 13 | 426 |
| − 15 | 159 |
| − 17 | 42 |
| − 19 | 4 |
| − 21 | 0 |
| − 23 | 0 |
| − 25 | 0 |
| − 27 | 0 |
| − 29 | 0 |
| Total | 65,536 |

The correct sign combination (known in this case since the structure is already known) is not one of the six giving the largest value of $\chi$, but is one of twenty-seven giving the next largest value. It would be quite feasible to investigate the $\rho$-distribution corresponding to each of about thirty sign combinations, but in fact in this case other criteria could be used for limiting the search still further.

We have also developed a method, which again makes use of the EDSAC, by which those sign combinations which give acceptably large values of $\chi$ can be singled out in a few minutes of machine time. We believe that in this way it will be possible to determine rapidly the structures of crystals of about the same complexity as the example we have mentioned. The method we have outlined would be particularly valuable when used in conjunction with X.R.A.C., which would provide a rapid means of testing the most plausible sign combinations.

A full account of this work will be published elsewhere.

## Cytoplasmic Particles in Bean Root Cells

In a recent report, E. Robinson and R. Brown[1] have described particles obtained by aqueous extraction from bean root cells which are similar to the isolated microsomes described by Claude[2], Brachet and Jeener[3] and Chantrenne[4]. The particles observed by the latter workers in extracts from many different animal tissues and from yeasts were found to contain ribose nucleic acid, whereas the results of Robinson and Brown suggest that the particles obtained by them may not contain ribose nucleic acid. Preliminary observations made by us on particles isolated from bean root cells by differential centrifugation indicate that particles containing ribose nucleic acid are obtainable from this material, and that the content of this substance varies with the size of the particle in the same way as with the particles isolated by Chantrenne[4] from mouse liver. The presence of the particles in the root-tip cells has also been demonstrated by an electron microscope study of thin sections of the root tips and of the isolated particles.

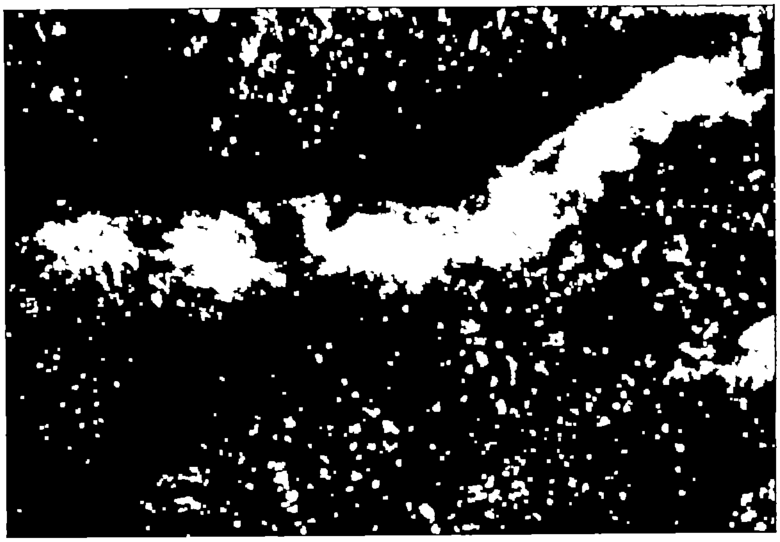
Roots were obtained by germinating seeds of broad bean on filter paper saturated with water at 20° C. The lateral root tips were harvested after seven days, care being taken not to include that part of the root distal from the tip where secondary thickening occurs, and the particles were isolated as follows:

The root tips were suspended in 15 volumes of $M/150$ phosphate buffer, $p$H 7·2, at + 4° C., broken up by a brief treatment with a blendor at low speed, and homogenized in a Potter homogenizer. Debris was then removed by two centrifugations at 1,400 $g$ for 10 min. at 0° C. The centrifugate, which contained a negligible amount of intact cellular material, was discarded. The opalescent supernatant was then centrifuged for one hour at 1,400 $g$, at 0° C., giving a centrifugate, $A$, which was resuspended in the buffer and washed by centrifugation at the same speed. Centrifugate $B$ was obtained by centrifuging the supernatant from $A$ at 25,000 $g$ for 1 hr. at 0° C., and was washed in the same way. Fraction $C$ was isolated from the supernatant of $B$ by centrifuging for 2 hr. at 130,000 $g$ in a Phywe ultracentrifuge at a mean temperature of 23·5° C.

| Fraction | Centrifuging conditions | mgm. RNA/mgm. N |
|---|---|---|
| $A$ | 1,400 $g$ for 1 hr. | 0·5 |
| $B$ | 25,000 $g$ for 1 hr. | 0·81 |
| $C$ | 130,000 $g$ for 2 hr. | 1·01 |

The centrifugates $A$, $B$ and $C$ were dispersed in small quantities of distilled water, and determinations of the nitrogen content per millilitre were made by a micro-Kjeldahl method. The ribose nucleic acid content of the suspended granules was estimated by the method of Ogur and Rosen[5]. Measured samples of the suspension were shaken with an equal volume of 5 per cent perchloric acid for 8 hr. at room temperature. The extracted ribonucleotides were estimated in a Hilger spectrophotometer by their absorption at 260 mμ, using a highly purified yeast ribose nucleic acid as a standard. The variation of the ribose nucleic acid content of the fractions with the condition of centrifugation is shown in the accompanying table. From this table it can be seen that the ribose nucleic acid content of the granules increases as the size of the granules decreases, as found in the case of animal material[4]. The magnitude of the ribose nucleic acid content and its variation with centrifuging conditions is of the same order as that observed previously[4] for liver microsomes.

The occurrence of the small particles inside the cells was also studied. The apical 4–5 mm. of roots of the same variety of beans were fixed in a bichromate and osmium fixative (Newcomer–Zirkle procedure[6]) and embedded in ester wax. The roots were cut longitudinally into sections of about 0·1 μ thickness



Thin section of a bean root. Magnification × 20,500. The cytoplasm is filled with small granules. Two larger cytoplasmic organelles ($A$ and $B$) which would be resolved by ordinary light microscopy can also be seen. The structure of particle $B$ appears slightly analogous with that of animal mitochondria (ref. 7) on a microtome, the design of which was begun in this laboratory by S. G. Tomlin and developed and completed by S. Fitton Jackson and W. E. Seeds (unpublished). The sections were examined in a Metropolitan-Vickers *EM*3 electron microscope at 75 kV. and a magnification of × 8,200. The cell walls showed middle lamellæ and did not appear to be distorted; they also contained dense bodies which were round in section. No precipitation effects were observed in the cytoplasm, which contained many particles of various sizes and types. The smallest particles observed were small dense bodies, the size of which was estimated very roughly as about 400 A. in diameter (see photograph). The particles which were sedimented at 130,000 *g* were also examined in the electron microscope, and were apparently identical with the minute cytoplasmic particles observed in thin sections.

The choice of the fixative was decided by the fact that it had yielded good structural preservation of the cytoplasmic organization of these cells, so far as could be ascertained with the light microscope. Improved methods of fixation are being developed, however, since this fixative gives variable results.

In our opinion, therefore, bean root tip cells contain cytoplasmic particles which, as regards their ribose nucleic acid content, are completely analogous to the particles studied by previous workers in animal tissues and in yeast. The particles described by Robinson and Brown very probably contain ribose nucleic acid also; a possibility which they took care not to exclude in their communication. We have recently learned from Dr. Robinson (private communication) that she too has now fractionated these particles in an ultracentrifuge and has obtained from them an absorption curve resembling that of nucleic acid.

We wish to thank Prof. J. T. Randall and Dr. M. H. F. Wilkins for encouragement in this work, and Dr. E. Robinson for helpful discussion. We also wish to thank Miss F. Ticehurst for help with the photography. One of us (J. C.) acknowledges a grant from the British Empire Cancer Campaign which enabled him to participate in this study. We are also grateful to the Rockefeller Foundation for the purchase of equipment used in this investigation.

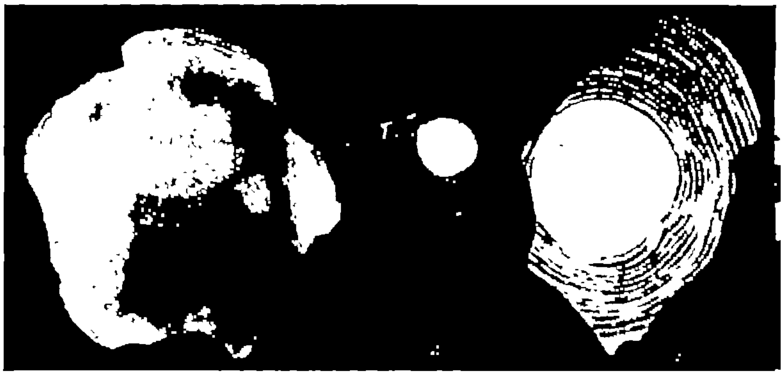
## Nuclei of *Cyclodypeus carpenteri* Brady

This beautiful large nummulite is collected now and then in the living state in the East Indian seas; but the major interest of the collectors always seems to be in the shell. We have, so far as I am aware, no description of the living animal, nor even of its pseudopodia; and nothing since the time of Lister[1] about its protoplasmic structures.

Lister gives a succinct account of what was then known of *Cycloclypeus*, with illustrations (ref. 2, pp. 130–132), and discusses the morphology of the shell with regard to its probable course of development. The initial chambers of both the megalospheric and the rare microspheric forms are described; and, in the case of the former, "a single large nucleus was found in one of the large central chambers" as figured in Lister (ref. 1).

Quite recently, by the good offices of Mr. Cameron D. Ovey of the British Museum (Natural History), London, there came into my possession two specimens preserved in neutral formalin, and sent by Miss Ruth Todd of the U.S. National Museum, New York. They are from a collection labelled U.S. 6184, "Outer slope, Bikini Atoll, Marshall Is.". The smaller specimen measured 11 mm. in its greatest diameter, and the larger one 25 mm. They are illustrated herewith.



*Cycloclypeus carpenteri*. (1) Microspheric, and (2) megalospheric, whole specimens; on the same scale. (3) The megalospheric form enlarged to show the whorls of chamberlets, partly decalcified, in the very thin peripheral parts of the empty shell

During careful decalcification in 70 per cent alcohol acidified with nitric acid, it became apparent that the smaller specimen was megalospheric, displaying the typical central shell structure shown by Lister (ref. 2, p. 131). Traces of the septal canals were seen in the organic shell matrix between the chamberlets, but no protoplasm remained in the shell. The canals contain, here and there, collections of the brown xanthosomes (? excretory granules), which are also present in patches elsewhere on the animal. The larger specimen, on the other hand, showed no indication of the robust central structure of this phase, and although its centre was not clear, it was certainly microspheric. The shell contained protoplasm, and pieces of the large fragile disk-like animal were stained in borax carmine and mounted in balsam on slides. In about a dozen of the middle whorls of chamberlets there appeared a large number (several hundreds in all) of rounded nuclei, some 15–20 $\mu$ in diameter, one to three in a chamberlet. No intranuclear structure could be made out. The 'heterostegine' type of protoplasmic intercommunication between the chamberlets is clearly seen, that is, connexions with adjacent chamberlets on either side in preceding and succeeding whorls, but none with neighbours of the same whorl; and the canal system full of protoplasm is also visible in the thick septa of the shell.

This note is published only partly in order to record the expected multinuclear nature of a microspheric *Cycloclypeus*. Our too fragmentary knowledge of this surviving protozoan prehistoric monster will no doubt some day be amplified, and a great part of the object in writing this letter lies in the hope that it may help to speed that day.

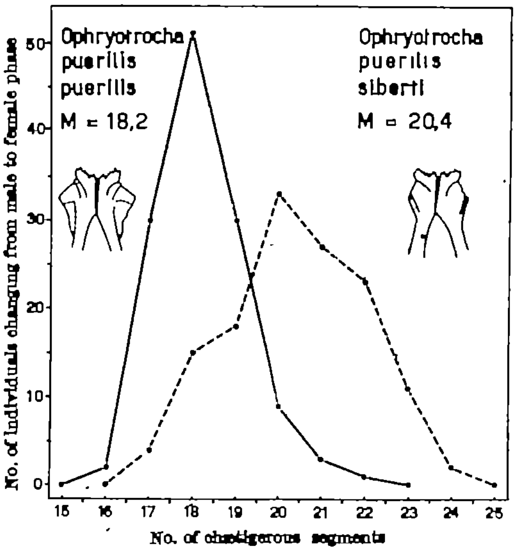
## Genetic and Morphological Evidence for Subspecific Differences between Naples and Plymouth Populations of *Ophryotrocha puerilis*

INDIVIDUALS of *Ophryotrocha* until now classified as *O. puerilis* and collected in the Bay of Naples and at Plymouth breed normally, if kept in Naples water, under conditions described elsewhere[1]. The Naples and the Plymouth populations are unquestionably closely related and have the same chromosome number ($2n = 8$). However, cross-breeding between a Naples individual and a Plymouth individual has constantly resulted in embryos which degenerated at an early stage and were eaten by their parents.

*O. puerilis* is known as a protandrous hermaphrodite[2]. Comparative studies of the first appearance and development of eggs in numerous individuals kept under identical conditions at a temperature between 17° and 18° C. gave the following results: (*a*) Small oocytes first appear in isolated Naples individuals at a mean size of eighteen chætigerous segments, whereas in isolated Plymouth individuals they appear at a mean size of twenty chætigerous segments (see graph). (*b*) The complete maturation of oocytes takes place in all the isolated Naples individuals, while the maturation of oocytes is seldom reached in isolated Plymouth individuals. (*c*) The Plymouth individuals in the female phase appear to reverse into the male phase more rapidly than the Naples individuals under the action of environmental factors[3]. This result may be partially explained by observations (*a*) and (*b*).

A careful morphological examination of the Naples and Plymouth specimens—both alive and preserved—revealed to one of us no substantial differences other than in the two parts of the mandibles (nomenclature from McIntosh[4]). The crenate apical portion of each of these pieces is supported by a plate which is comparatively large in the Plymouth individuals, but is much reduced or even absent in the Naples individuals. The wing-like border occurring close behind the anterior region is also rather elongated in the Plymouth strains, more triangular and broader in the Naples strains (see graph).



*Ophryotrocha puerilis puerilis* (continuous line) and *O. puerilis siberti* (broken line). Left: mandibles of *O. puerilis puerilis*; right: mandibles of *O. puerilis siberti*

In a survey of the available literature on the Mediterranean and Atlantic *Ophryotrocha*, no detailed observations have been found on the structure of the mandibles; but some information has been collected by the examination of some carefully drawn outlines of the armature[4] of the proboscis. It appears, for example, that the *Ophryotrocha* from Whitstable oyster beds described by McIntosh[5] under the name *Staurocephalus siberti* almost certainly corresponds to the Plymouth *Ophryotrocha* now being cultivated in the Naples Zoological Station.

From a strictly genetic point of view, the *Ophryotrocha* from Plymouth now studied should be named as a separate species from the Naples *Ophryotrocha* which is the true *puerilis*, since Claparède and Mecznikow[6] collected their specimens in the Bay of Naples. However, a number of considerations, which will be discussed elsewhere, induce us to adopt the trinomial nomenclature (*Ophryotrocha puerilis puerilis* Clap. and Meczn. from the Bay of Naples, and *O. puerilis siberti* McInt. from Whitstable and Plymouth) in order to stress the close relationship between the two populations.

A more detailed paper on this subject will be submitted elsewhere.

Our thanks are due to Mr. F. S. Russell, and to the staff of the Marine Biological Laboratory, Plymouth, for the many courtesies extended to us.

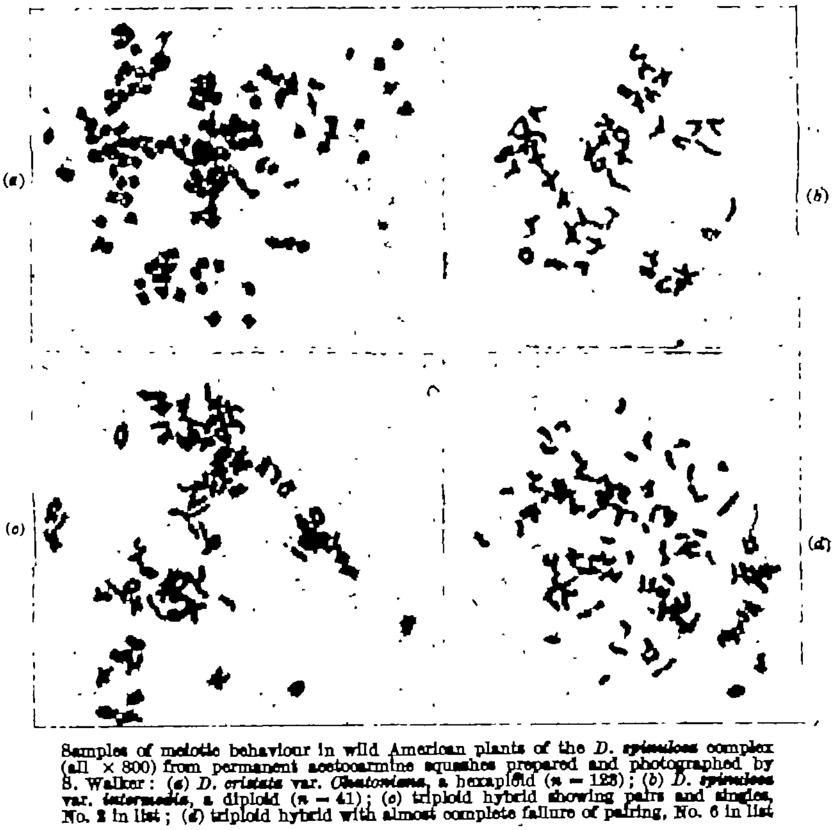
In America the situation seems to be more complicated. There are a greater number of named types, including both species and hybrids, and we have reason to think that these do not exhaust the number of cytologically distinguishable entities which exist. The above list gives some preliminary cytological observations made on wild American specimens sent to us by the kindness of Prof. R. H. Wetmore of Harvard and of Dr. W. H. Wagner, jun., formerly of Harvard and now of Michigan. The nomenclature used is that of Gray's "Manual"[2] and the identifications have been authenticated before dispatch from America by Dr. Wagner and confirmed, after completion of the cytology in Leeds, by Mr. A. H. G. Alston of the British Museum, to all of whom we are most grateful.

Commenting on this list, it should be noted that the two diploid species *D. goldiana* and *D. marginalis* placed at the end as Nos. 9 and 10 are not in themselves included in the *spinulosa* complex, but information about them is needed since they are involved in certain hybrids, notably No. 11 and perhaps No. 7.

Within the complex itself, *D. cristata* (No. 5) is the same as in Europe, namely, tetraploid. *D. cristata* var. *clintoniana* (No. 7), however, being hexaploid, is perhaps the amphidiploid hybrid between normal *D. cristata* and *D. goldiana*. We have not so far found any evidence that the European tetraploid *D. dilatata* is present in America unless it be the *D. spinulosa* var. *americana* which we have not yet examined. On the other hand, tetraploid *D. spinulosa* (No. 1) is certainly present, though the fact that some of the plants sent to us from each of two localities under this name were triploids (No. 2) suggests that there is something else breeding with *D. spinulosa* (typical) and possibly resembling it morphologically, but diploid.

We do not think that the undoubtedly diploid *D. spinulosa* var. *intermedia* (No. 3) is the form in question, since the putative hybrid between this variety and *D. spinulosa* (typical) has a different morphology which is well known under the name of *D. spinulosa* var. *fructosa* (No. 4). There is also the evidence of the putative hybrids with *D. cristata*. These are of two kinds. The wild hybrid thought to be *D. cristata* × *D. spinulosa* var. *intermedia* (No. 6) is known as *D. boottii* and, as expected, it proves to be triploid with almost complete failure of chromosome pairing. Another wild hybrid (No. 8) of different morphology was sent to us as probably *D. cristata* × *D. spinulosa* (typical). In morphology, this resembles closely the European hybrid (*D. uliginosa*) of this constitution, which is tetraploid[1]. The American hybrid is, however, yet another triploid with complete failure of chromosome pairing, suggesting that its parentage cannot involve typical *D. spinulosa* itself but could involve the unknown diploid.

We would be grateful for further supplies of American material bearing on this problem, and in the meantime the mutual relationships of American



Samples of meiotic behaviour in wild American plants of the *D. spinulosa* complex (all × 800) from permanent acetocarmine squashes prepared and photographed by S. Walker: (*a*) *D. cristata* var. *Clintoniana*, a hexaploid ($n = 123$); (*b*) *D. spinulosa* var. *intermedia*, a diploid ($n = 41$); (*c*) triploid hybrid showing pairs and singles, No. 2 in list; (*d*) triploid hybrid with almost complete failure of pairing, No. 6 in list and European forms are being investigated by a programme of controlled breeding.

## Effect of Nitrogen Mustard on an Inherited Character in the Rat

IN 1949, the late P. Ellinger[1] described some experiments which suggested that treatment of rats with nitrogen mustard had produced a mutation in the gene or genes controlling the output of nicotinamide methochloride. He followed up this work with some extensive experiments, and recently asked me to analyse the results. Prof. Ellinger died before I had the opportunity of discussing with him the results of the analysis, and this communication is therefore published without the benefit of his advice.

Ellinger mated a given pair of parents twice, first without treatment, and again one day after treatment of one or both parents with nitrogen mustard (0·2 mgm./kgm. injected intraperitoneally). The daily nicotinamide methochloride output of each member of the two litters was measured. Ellinger reported four such experiments, in two of which the mean output of the offspring born after treatment of the parent was significantly lower than that of the offspring born before. Such an effect can be attributed to a gene mutation or a chromosome rearrangement only if there is, in the absence of the treatment, no litter-to-litter variation of a similar magnitude. In a genetic study of the nicotinamide methylating mechanism, Ellinger and Armitage[2] found the output to be controlled by a number of genes, but also subject to considerable environmental fluctuations. It therefore seemed possible that the changes observed in the nitrogen mustard experiments were environmental rather than genetic, and unconnected with the treatment.

The results are now available of thirty-nine non-sterile matings, in which litters were produced before and after treatment of one or both parents with nitrogen mustard. Usually, $F_1$ litters were produced by mating rats within the post-treatment litter, and often subsequent generations were obtained. In sixteen of the thirty-nine primary matings, the mean logarithm of output was higher in the litter produced after treatment than in that produced before, and in twenty-three the mean was lower. There is evidently no strong evidence of a systematic rise or fall in mean logarithm of output after treatment. In four matings the change in the mean logarithm of output was particularly marked (at least 0·40 logarithmic unit). Further examination of the results of these four matings suggests very strongly, however, that the changes were not genetic. In the first place, each of these changes affected the whole litter rather than (as would have been expected had a mutation occurred) an individual rat. Secondly, the output of $F_1$ rats, one of whose parents had an abnormally high or low output, always reverted to about the level of the treated animals and of their pre-treatment offspring. Finally, a comparison is possible with some data on untreated animals[2]. Five pairs of untreated rats each produced two litters. For four of these pairs the two litter means were very similar. In the fifth case the difference in mean logarithm of output was 0·34, a difference greater than most of those found in the nitrogen mustard experiments.

It must be concluded that the observed changes in output are probably due to environmental causes unrelated to the nitrogen mustard treatment.

## Function of the Foot in the Lucinacea (Eulamellibranchia)

THE Lucinacea, comprising the families Ungulinidæ, Thyasiridæ and Lucinidæ, all have a characteristically slender vermiform foot. Its anatomy has been described by Barrois[1] and Menégeaux[2] and its locomotory movements by Stoll[3]. In some species, for example, *Diplodonta rotundata*, the slightly bulbous tip is distinct from the rest of the foot. The foot can extend four or five times the length of the animal and the tip can swell out even when the foot is extended. When the foot is contracted, it lies with the tip close to the posterior edge of the anterior adductor muscle. This muscle (Fig. 1) is characteristically elongate.

These animals live in a variety of soft substrata from sand to mud, both intertidally and sublittorally, to great depths. They burrow to a depth that is equal to the length of the extended foot. All Lucinacea have anterior and posterior inhalant currents.

It has been found that, in addition to its normal movements for burrowing and locomotion, the foot forms an anterior inhalant tube lined with mucus. This has been demonstrated in *Loripes lucinalis*, *Thyasira flexuosa* and *Phacoides borealis*. This habit

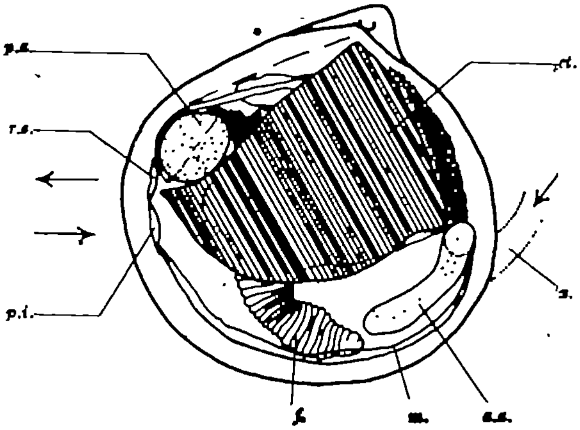

Fig. 1. *Loripes lucinalis*, with right valve removed. *a.a*, anterior adductor; *ct.*, ctenidium; *f.*, foot; *m.*, mantle edge; *p.a.*, posterior adductor; *p.i.*, inhalant aperture; *r.s.*, retracted exhalant siphon; *s.*, position of the anterior inhalant tube

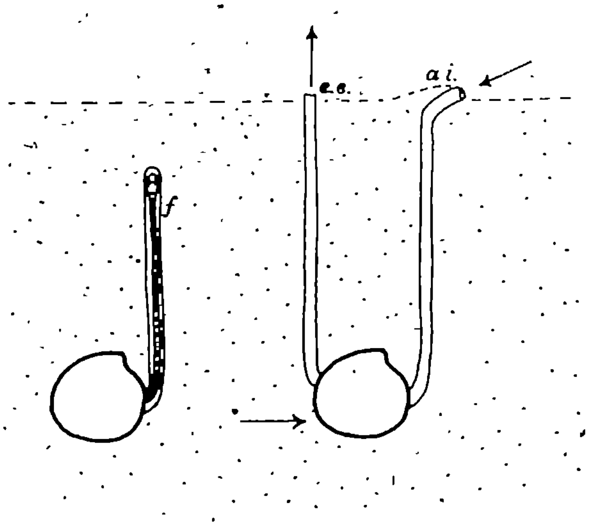

Fig. 2. Form and position of anterior inhalant tube of *Loripes lucinalis*. *f.*, foot; *a.i.*, anterior inhalant tube; *e.s.*, extended exhalant siphon

was discovered when observations were made on the burrowing mechanism of *Loripes*. The animals were allowed to burrow in specimen tubes containing sand taken from the place they were collected. Some animals came to lie by the side of the tube so that the movements of the foot could be observed. When they had buried themselves to a depth of approximately 4 cm., the foot was observed to issue from between the valves at the anterior end of the anterior adductor and gradually force its way to the surface. In these observations the foot alternately extended and contracted, each extension being longer than the last until the surface was reached. The foot secretes the mucus lining the tube. Microscopic examination of the epithelium of the foot shows numerous mucus-secreting cells which are most dense near the tip.

The tube does not open vertically to the surface but turns for two or three millimetres along the surface of the substratum (Fig. 2). After twenty-four hours, it was found that the sand could be washed from the specimen tube leaving the anterior inhalant tube intact and fastened to the glass. The tube extends from the anterior end of the anterior adductor, while the mantle between the adductor and the shell edge (Fig. 1) forms a continuation of the tube into the mantle cavity. This inhalant channel is additional to the posterior inhalant aperture. The relative importance of the two inhalant currents and the effect of the anterior one on the ciliary currents within the mantle cavity will be discussed elsewhere.

The foot is periodically protruded after the tube has been formed, and its main function is to keep the tube, and particularly the aperture at the surface, free from debris. If the entrance is deliberately blocked, the foot is almost immediately protruded and clears the obstructing particles, often laying down an additional short length of tube. Once the tube has been formed the animal remains in this position for a considerable period.

*Loripes lucinalis*, which was obtained from the sandy beaches at Roscoff, was carefully examined in the field. The position of the anterior inhalant tube was clearly marked in the sand by a rust-coloured deposit which also discoloured the part of the shell where the tube enters. This colour is due to fine surface sediment that has been drawn into the tube. Carmine particles were accepted, and although it was not possible to keep the specimens long enough for the tube to become discoloured, the shell in this region did become coloured with carmine.

A mucous tube is not laid down by the posterior exhalant siphon when this is present. Yonge[4] showed that in *Thracia pubescens* separate mucous tubes are formed by the siphons. In some gastropods essentially the same type of tube is formed by the proboscis. This has been demonstrated by Yonge[5] in *Aporrhais* and by Morton[6] in the Struthiolariidæ. Thus the Lucinacea show a third method of forming a mucus-lined tube.

I acknowledge the help and kindness of Prof. P. Drach and the staff of the Marine Station, Roscoff, and also of Prof. C. M. Yonge. Thanks are due to the John Murray Committee of the Royal Society for financial assistance.

## Some Relationships between Morphology and Antigenic Structure in Bacteria

THE problem of correlating morphological with antigenic concepts in bacteria has made surprisingly little progress since the flagellar, capsular and somatic antigens were first recognized. Antigenic analysis has indeed required that certain somatic antigens should be regarded as occupying locations nearer or farther from the surface of the cell, but this is almost the entire extent of the concept.

Information does, however, appear to be available, which enables certain antigenic phenomena to be explained in morphological terms. The observation of Pijper[1] that somatic agglutination of typhoid bacteria occurs by the adherence of the poles of the cells, whereas in *Vi* agglutination the entire surface is affected, has a logical explanation when it is realized that the basophilic material associated with the growing-point of the cell is concentrated at the poles, where it is covered by an exceptionally thin cell wall or by none at all[2]. In Rough variants the arrangement of the growing points is entirely different, as they have a characteristic septate structure[3]. Thus we may logically assume that the secretory nucleo-proteins of the growing point represent an important somatic antigen, whereas the *Vi* antigen is a surface material.

The well-recognized fact that the Gram-positive genera constitute, as a rule, much less satisfactory antigens than the Gram-negative, can be explained in part by the fact that the former commonly have a similar septate structure to that of the Rough variants of Bacteriaceae[4]. In this type of structure the metabolically active growing-points, and the cytoplasmic septa, which precede and secrete the cross-walls, and which appear to be similar in both function and constitution to the growing-points, are mainly internal instead of being exposed at the surface. At the same time, the cell envelopes of the Gram-negative genera have been shown to have a higher lipid content and a much fuller range of amino-acids in the protein fraction than have those of the Gram-positives[4]. Their cytochemical behaviour more closely resembles that of intact wool proteins, whereas the Gram-positive cell envelopes resemble degraded wool proteins in this respect[5].

From these observations the following conclusions can be drawn; they are not completely proved, but must be regarded as intrinsically much more probable than the contemporary hypothesis (which most bacteriologists probably do not take very seriously) of antigenic variation by progressive loss of surface layers like the leaves of an onion. The well-known $S \rightarrow R$ variation in the pneumococcus is, of course, concerned with the loss of the capsule and is not referred to.

(*a*) The nucleoprotein material of the growing points is an important somatic antigen.

(*b*) The 'loss' of certain somatic antigens in Rough variants of Bacteriaceæ is due rather to the alteration in position of this material from a surface to an internal site than to its actual disappearance.

(*c*) The loss of further somatic antigens in Rough variants, and the low antigenicity of Gram-positive genera, are due to the chemically simpler structure of the cell envelopes in bacteria of septate morphology.

## Sporulating Anaerobes on English Flax

ALLEN[1] reported that the majority of spore-bearing anaerobes isolated in pure culture from anaerobic and aerobic flax-rets in England, and which appeared usually to be the active agents in retting, possessed the characteristics of *Clostridium ertium*. Dowson[2] found that *Bacillus polymyxa*, a facultative sporulating organism, was capable of causing a soft rot of potato. This organism is capable of attacking pectin and therefore has potential retting abilities. *B. amylobacter* Bredemann, which is a synonym of *Cl. butyricum* and wrongly includes more han one true specific group[3], is mentioned in the literature as a retting organism[4]. So far as I am aware, no other strict anaerobe, facultative anaerobe or micro-aerophilic organism has been reported in England as a possible retting agent.

In other leading flax-retting countries, however, *Cl. pectinovorum*, a plectridial anaerobe, and *Cl. felsineum*, an orange-pigmented anaerobe, are conidered to be the major retting agents, the latter being superior to the former. *Cl. tertium* has not been cited, except by Lanigan[5], who observed that a micro-aerophilic species related to *Cl. tertium* but differing from the latter in that it liquefied gelatin was most commonly found on Australian flax. *B. polymyxa*, if found, is considered of minor importance. Hellinger[3] found *Cl. aurantibutyricum*, an orange-pigmented butyric acid-producing organism, and *Cl. pectinovorum* var. *pseudoplectriforme*, to be commonly distributed in Israel flax rets. *Cl. aurantibutyricum* proved to be a highly efficient retting organism comparable to *Cl. felsineum*.

I have recently been investigating the microbial flora, more especially the sporulating anaerobes, on samples of English flax from Norfolk, Suffolk and Wiltshire. Straw samples were placed under simulated retting conditions, that is, immersed in water at 32° C., and sporulating anaerobes were isolated in pure culture using maize mashes, yeast–glucose–chalk media and potato/yeast–glucose agar slants in test-tubes under anaerobic conditions. A micro-aerophilic plectridial organism classified as *Cl. pectinovorum* (cf. Weizmann and Hellinger[6]), and *Cl. butyricum* were invariably present and numerous in all samples. An orange-pigmented anaerobe was found; but it formed a small part only of the flora of some of the flax. It was identified as *Cl. aurantibutyricum*, and not *Cl. felsineum*. *B. polymyxa* was obtained, but it was present in extremely small numbers.

The English isolates of *Cl. pectinovorum* were compared with a typical strain of the organism obtained from Prof. Kluyver of Delft, and a strain of *Cl. tertium* (541) obtained from the National Collection of Type Cultures. Studies carried out with these organisms tend to show that *Cl. tertium* is identical with *Cl. pectinovorum*. The strains examined were micro-aerophilic and also liquefied gelatin, the former a feature characteristic for *Cl. tertium*, the latter a distinguishing feature of *Cl. pectinovorum*.

The flax-retting abilities of the organisms isolated were tested on sterilized flax straws according to the method of Hellinger[3]. The new isolates of *Cl. aurantibutyricum* were remarkably active. Retting progressed moderately well after 48–54 hr. and the fibre bundles were completely liberated from the stem matrix after 66 hr. None of the strains of *Cl. pectinovorum*, including also the Dutch strain and *Cl. tertium* (strain 541), showed any sign of retting in 6–11 days at 32° C. Continuous aeration was tried, but also gave negative results. The *Cl. butyricum* isolates were also ineffective, whereas *B. polymyxa* caused a certain amount of loosening of the fibre bundles.

It is perhaps possible that *Cl. tertium* (strain 541) and the Dutch strain of *Cl. pectinovorum* had lost their original retting ability on long-continued artificial cultivation.

Full details of this work will be given elsewhere. It was done while on leave from the Weizmann Institute of Science, Rehovoth, Israel. Grateful acknowledgments are due to Mr. Gillham, Directorate of English Flax Production of the Ministry of Materials, and Major Searle, director of H.M. Norfolk Flax Establishment, King's Lynn, for their ready co-operation in giving me laboratory facilities and assistance.

## Rooting of Cut Shoots of Cotton in Culture Filtrate of *Fusarium vasinfectum*

A study was made of the toxicity of culture filtrates of the cotton-wilt pathogen, ***Fusarium vasinfectum*** Atk., grown in synthetic Czapek's medium, to cut shoots of cotton. This indicated that, under laboratory conditions, the culture filtrate (fourteen days old) when dialysed against distilled water at 4–5° C. for four days to rid the crude filtrate of metabolites—earlier observed to be toxic to the plant—brought about typical wilt symptoms, which have been described in detail elsewhere[1]. Higher dilutions of this dialysed neat filtrate did not produce any symptoms of toxæmia, but induced rooting. However, the dialysed filtrate autoclaved at 15 lb. pressure for 15 min. (with the view of inactivating the toxin) induced profuse rooting in the cut shoots of cotton at all concentrations, and in no case were there any typical wilt symptoms.

These observations indicate that the dialysed culture filtrate of ***F. vasinfectum*** probably contains two or more factors: (i) a thermolabile factor producing wilt symptoms at higher concentrations; and (ii) a thermostable factor stimulating vigorous rooting in the cut shoots even at dilutions. It is likely that the latter factor is ineffective in the presence of higher concentrations of the former, since at these concentrations of the neat dialysed filtrate only typical wilt symptoms are produced, but not rooting.

So far as we are aware, stimulation of rooting of cut shoots of cotton plants by dialysed fungal filtrates has not been previously reported, and it is therefore considered worth while to record this interesting phenomenon. Detailed work on the nature of the factor or factors contained in the dialysed filtrate and their interaction with each other and also their effects on cut shoots of different host plants are now under way, and the results of these investigations will be reported in detail elsewhere.

We thank Prof. T. S. Sadasivan and Dr. C. V. Subramanian for their suggestions and guidance.

## High Molybdenum Levels in Herbage on Acid Soils

It is generally considered that there is a marked correlation between molybdenum uptake by plants and soil reaction. Evans *et al.*[1] and others have shown that a change in reaction from strongly acid to alkaline results in increased uptake, especially in the alkaline region. So far as we are aware, all cases of molybdenum deficiency hitherto reported have been in acid soils, while excess levels of molybdenum in herbage, responsible, in part at least, for complicated copper-deficiency effects in livestock, have been reported only from slightly acid to strongly alkaline soils. This in general has also been our experience[3]. However, in an extension of our work, a case has been found where the conditioned copper-deficiency syndrome occurs in cattle confined to pasture growing on strongly acid soils. It was thought at first that this might possibly be a case of simple copper-deficiency. The animals were severely affected. Blood samples showed copper values varying from 0·03 to 0·07 mgm. per cent. Herbage samples taken from the pastures concerned showed copper values in the region of 13 parts per million and molybdenum values of 7·0–13·0 p.p.m. The herbage consisted of bent grasses, crested dogstail, Yorkshire fog, *Juncus* spp., sedges and other species typical of poor pasture on acid soils.

The soil in the area concerned, while situated on the slope of a drumlin, is moderately impeded. The surface soil (0–8 in.) is a grey-black silt loam and overlies a grey, slightly mottled brown, plastic clay loam sub-soil. Representative soil samples showed a *p*H varying from 4·9 to 5·2 with a calcium exchange-level of 5 m. equiv. and hydrogen exchange-level of 14 m. equiv. per 100 gm. Organic carbon averaged 12 per cent. These samples also showed very low levels of available potash and phosphate. The total molybdenum content varied from 2·1 to 3·00 parts per million, with a readily available level of 0·80–0·90 p.p.m., as determined by Grigg's oxalate method. These are the highest readily available molybdenum levels so far recorded by us, a threshold value for excess levels in slightly acid to alkaline soils being 0·30 p.p.m.[3].

The fact that there has been a relatively high uptake of molybdenum by herbage plants in these strongly acid, low calcium soils is consistent with the finding of Stout *et al.*[2], who, using culture solutions, showed that absorption of molybdenum by plants is far greater from acid soils than from soils of neutral reaction. It is possible that in the soils investigated by us the agents responsible for the fixation of molybdenum may be absent, and it is thought likely that this may be associated with the reduced condition of the soil and its organic matter content. This aspect of the problem is being investigated. The experience obtained indicates that it is desirable to extend considerably the range of soil conditions, especially where reaction is concerned, under which excess molybdenum uptake by herbage may be expected.

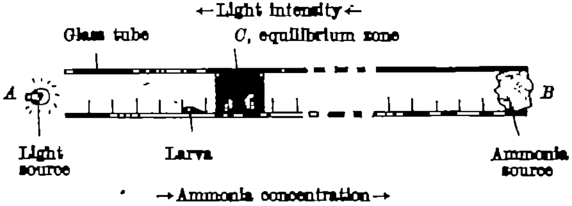
## A Simple 'Response Balance' for studying Insect Behaviour

The responses shown by insects to insecticides are usually measured in terms of paralysis or death. Since the insects lose their power of co-ordinated movement during the primary stages of poisoning they cannot respond to stimuli which modify their normal behaviour. When the concentration or dosage of insecticide is very low, however, insects may be irritated or repelled by the insecticide without loss of muscular co-ordination. Under such conditions the responses shown to other stimuli, for example, a light stimulus, become of interest, especially where the



Apparatus for measuring responses shown by insects to light and chemical stimuli

kinetic effects of the chemical and light stimuli are opposed. In the present communication, a description is given of an apparatus, or 'response balance', used for studying systems of this kind (see diagram).

The apparatus consisted essentially of a glass tube 24 in. long and 1 in. internal diameter. A 60-watt lamp connected to a variable resistance was placed near end *A*, and a plug of cotton wool soaked in the repellent was inserted in *B*. The apparatus was used in a dark room at 20° C.

In a typical experiment, mature *Calliphora* larvæ, which are negatively phototropic, were used as test insects; the source of repellent vapour was a strong ('880') solution of ammonia. Five larvæ were placed in the tube at *A* and the light intensity gradually increased until the larvæ started crawling towards the ammonia source. With increasing concentration of ammonia vapour the repellent stimulus became stronger, and the larvæ frequently turned round towards the light, then back towards the ammonia source. At this stage the light source was kept constant; the larvæ crawled about at random within restricted equilibrium zones (*C*), 2–3 in. in length, where the kinetic effect of the light stimulus balanced that of the chemical stimulus. When the light source was dimmed, the chemical repellent stimulus became the dominant factor, and the larvæ crawled towards the light, the equilibrium zones being displaced in this direction; the effect was reversible, the larvæ moving towards the ammonia source when the light was made brighter.

*Sensitizing effect of kerosene on chemoreceptors.* The sense organs of insects are bounded by a thin cuticular sheath[1]. Since it was known that oils, such as kerosene, greatly increase the permeability of the cuticle of *Calliphora* larvæ to a variety of chemical substances and insecticides[2], experiments were tried to see whether kerosene might sensitize the chemoreceptors in this insect to ammonia vapour. The above experiment was repeated using (*a*) five mature larvæ as controls, and (*b*) five mature larvæ which had been lightly painted with kerosene. Values obtained to the nearest inch for the distance *B*–*C* between the ammonia source and the mid-point of each equilibrium zone were:

*controls*, 8, 7, 7, 5, 4 in.;
*oiled larvæ*, 17, 14, 13, 12, 10 in.

A similar experiment was carried out in which test larvæ were painted with medicinal paraffin instead of kerosene. Values obtained for *B*–*C* were:

*controls*, 9, 7, 6, 6, 4 in.;
*oiled larvæ*, 11, 8, 6, 5, 5 in.

The observations that kerosene, but not medicinal paraffin, sensitizes *Calliphora* larvæ to the repellent action of ammonia vapour suggest that chemoreceptors stimulated by ammonia are made more sensitive by an increase in cuticle permeability. A similar difference between the effects of these oils on the uptake of contact insecticides had already been correlated with their relative dispersive actions on the lipids of the outer fatty epicuticle bounding the bulk cuticle framework[3].

*Lethal effect of ammonia vapour.* When the light source was made very intense, control and kerosene-treated larvæ crawled nearer to the ammonia source until they began to roll about at random, showing a loss of neuro-muscular co-ordination. There were no sharply defined equilibrium zones, and when the light was dimmed the larvæ did not crawl away from the ammonia source as observed for larvæ in contact with lower concentrations of ammonia vapour. Within a few minutes the larvæ became paralysed; they were removed from the tube and kept in open Petri dishes, where they died within 10–15 hr. The initial kinetic effect of the light stimulus was thus greater than that of the opposing chemical stimulus, even though the larvæ moved into a lethal concentration of ammonia.

Although irritant vapours, such as ammonia, may stimulate a variety of sensory endings in insect cuticle[4], the sensitizing effect of kerosene on these receptors suggests that fatty components similar to those in the bulk epicuticle may act as a protective barrier in the cuticular sheaths of sensilla, including those which act as more specific organs of smell and taste. This view may have some bearing on the findings of Dethier and Chadwick[5] that the lipid solubility of different chemical substances is related to their stimulating activity on the tarsal organs of taste in *Phormia*.

This report is based on work begun at the Department of Zoology, Imperial College of Science and Technology, and continued at the Department of Colloid Science, Cambridge. A full account will be given elsewhere.

## Significance of Nannoplankton

ATKINS[1], in 1945, reported on the productivity of the English Channel as estimated by two independent methods. The silicate turnover indicated a far lower productivity than did the phosphate turnover, and from this he deduced that only a relatively small fraction of the phytoplankton could consist of forms with siliceous skeletons. Knight-Jones and Walne[2] later showed that the very small nannoplanktonic form, *Chromulina pusilla*, was present in English Channel waters in numbers averaging about 1,000 per ml. They quoted other work showing that as much as 90 per cent of the phytoplankton may be small enough to pass through a fine silk tow net, and 40 per cent through a No. 2 Whatman filter paper.

The Florida current off Miami was sampled for a period of one year, and the phytoplankton content, as indicated by metered Clarke–Bumpus No. 20 net hauls, was compared with the results from samples filtered through a No. 54 Whatman filter paper. The results are shown in the accompanying table.

PHYTOPLANKTON CONTENT OF FLORIDA CURRENT WATER IN HARVEY UNITS PER CUBIC METRE

In this area, one H.U. is approximately equivalent to 0·017 mgm. of organic carbon

| Net haul | Paper-filtered | Filtered / Net |
|---|---|---|
| 0·42 | 401 | 955 |
| 0·61 | 448 | 734 |
| 0·87 | 1,380 | 1,586 |
| 4·68 | 6,750 | 1,442 |
| 5·60 | 1,660 | 296 |
| 6·10 | 657 | 108 |
| 6·37 | 7,950 | 1,248 |
| 6·70 | 1,540 | 230 |
| 7·65 | 9,220 | 1,205 |
| 17·8 | 20,000 | 1,124 |
| 18·7 | 23,350 | 1,249 |
| 19·7 | 20,950 | 1,063 |
| 59·1 | 57,600 | 975 |
|  |  | Mean 937 |

In this area, then, the nannoplankton is rather consistently about a thousand times as rich as the fraction of the phytoplankton which can be captured with a net. While the ratio appears very high, it may be pointed out that Hart[3] demonstrated a great increase in the proportion of armoured dinoflagellates in lower latitudes as compared with antarctic seas. Between 60° and 40° S., they averaged only 7 per cent of the phytoplankton, whereas between 40° and 20° S. they averaged 63 per cent. If the nannoplanktonic forms are considered to be largely unarmoured dinoflagellates, then it is not unexpected that they should constitute a high proportion of the phytoplankton in warmer waters. In any event, it is clear that net hauls provide a quite inadequate picture of the standing crop of phytoplankton.

# Hormonal Nature of Extracts of Parathyroid Gland stimulating Phosphate Excretion

Stewart and Bowen[1] have recently reported that preparations of parathyroid hormone after treatment with formaldehyde lose their power to raise the serum calcium-level of dogs, while still remaining able to increase the excretion of urinary phosphate. In view of these results, we wish to report on the properties of certain extracts obtained from ox parathyroid glands by a different method.

In our work acetone powders, made from frozen glands by the method of Tepperman, L'Heureux and Wilhelmi[2], have been extracted at 75° with 15 parts of 80 per cent acetic acid. After 5 min. at this temperature, heating was stopped and extraction was continued for 1½ hr. Mechanical stirring was maintained throughout. After centrifugation and removal of most of the acetic acid *in vacuo*, such extracts were dialysed for one week at 0° against a large volume of dilute acetic acid. Both the material which remained inside and that which passed through the membrane were tested by subcutaneous injection into parathyroidectomized rats. After appropriate times, the resulting changes in serum calcium[3], serum phosphate or urine phosphate[4] were measured.

The results of such tests summarized in the accompanying table show that, like Stewart and Bowen, we have succeeded in obtaining material from the parathyroid gland which is able to increase the excretion of phosphate in the urine without having any direct effect on the serum calcium-level. Because at least some of the phosphate-stimulating material in our 80 per cent acetic acid extracts consists of molecules small enough to pass through a 'Cellophane' membrane, we have not had to resort to the use of a protein denaturing agent such as formaldehyde to achieve dissociation of the two activities. Whether the parathyroid gland normally secretes a single molecular species active in relation to the blood-level, and the excretion, of both calcium and phosphate remains one of the most interesting questions for the future. Alternatively, it may possibly be that the hydrochloric acid – acetone procedure of Tepperman *et al.* leads to an association of originally separate molecules.

TESTING OF PARATHYROID EXTRACTS

| Extract | Increase in serum calcium | Increase in urine phosphate | Decrease in serum phosphate | Increase in serum calcium | Increase in urine phosphate |
|---|---|---|---|---|---|
|  | Material which had passed through 'Cellophane' membrane |  |  | Material unable to pass through membrane |  |
| *A* |  | + (0·04) |  |  | + (0·4) |
| *B* |  | + (0·4) |  |  |  |
| *C* | No change (40) |  | + (1·2) | + (81) |  |
| *D** | No change (57) |  |  | + (10) |  |

Amount of material injected per rat (mgm.) is shown in brackets. Average number of animals used per test: urine phosphate 56, serum phosphate 32, and serum calcium 14. Since there were large differences between the responses of individual rats in the serum and urine phosphate experiments, rather large numbers of animals had to be used. In these tests all the results were significant, $P < 0{\cdot}02$. The serum calcium of the rats used to test the diffusible material showed an average fall of 5 per cent (due to taking blood samples) whereas the non-diffusible material caused an average rise of 16 per cent.

* Extract *D* was made by extracting under similar conditions but for 50 min. instead of 5 min.

In view of the above separation of the phosphate activity from that concerning calcium metabolism, it is of interest to consider whether the effect of the parathyroid gland on phosphate metabolism is due to a hormone or to a non-specific factor. That such a hormone exists, either as part of the calcium-active hormone or as a separate molecular species, is suggested by the observation of Engfeldt[5] that after parathyroidectomy the serum inorganic phosphate of rats rises for a few days and then remains steady at a level some 2 mgm. per cent higher than that before operation. Even more important is the finding of Tweedy, Chilcote and Patras[6] that the urinary phosphate excretion of rats becomes very sensitive to parathyroid hormone immediately after parathyroidectomy. We have recently confirmed that result and have observed that the increased sensitivity does not diminish for several weeks after operation. Corresponding falls in serum inorganic phosphate have also been noted after amounts of hormone so small as to cause only very slight decreases in the normal rat.

Despite these points, Stewart and Bowen do not suggest that the phosphate-eliminating effect is due to a hormone, their reason being that they extracted phosphate-eliminating material from both thymus and spleen by the same method as that used by Tepperman *et al.* for preparation of the parathyroid hormone. They consider rather that extracts of all three glands are able to stimulate the excretion of phosphate by virtue of their content of "pharmacologically active tissue degradation products".

Although there is not as yet sufficient evidence for the secretion by the thymus or spleen of a hormone effecting phosphate metabolism, the facts summarized above on the results of extirpation of the parathyroid would seem to show that this gland at least secretes a factor necessary for the maintenance of normal phosphate excretion. Although the method of extraction of thymus and spleen used by Stewart and Bowen no doubt yielded a preparation consisting largely of protein, it is of interest that Nitschke[7] prepared extracts of thymus and spleen having fatty properties which were found markedly to depress the serum inorganic phosphate of dogs. While such material if present as lipoprotein could presumably explain Stewart and Bowen's results, it would appear to have different physico-chemical properties from the phosphate-eliminating extract prepared by us from parathyroid glands. The most important conclusion seems to be that the excretion of inorganic phosphate by the kidney is under the control of a hormone secreted by the parathyroid. Whether the extracts of other glands which have been shown to have activity in this respect contain the same or similar hormones or only non-specific factors remains to be determined. However, it seems certain that whatever the role of the factors derived from other tissues, the secretion of the parathyroid must be quantitatively of considerable importance since extirpation of this gland causes marked effects.

Finally, it should be noted that although, so far as the phosphate effect is concerned, the products of parathyroid and thymus seem to act in the same sense, this is probably not true in relation to their effects on serum calcium. Thus Nitschke[7] has reported extracts of thymus and spleen insoluble in fatty solvent, which he claimed led to a lowering of serum calcium. It would clearly be of interest to know what effect, if any, Stewart and Bowen's thymus extracts have on serum calcium.

## Asparagine in Blood Plasma

FREE asparagine has twice before been reported in animal tissues, namely, in the liver, kidney and spleen of sheep[1], and, recently, in human urine[2]. The evidence given below shows that it is also present in the blood plasma of both man and the goat: the concentrations are, in fact, comparable to those of many other free amino-acids in blood plasma.

If an amino-acid mixture is analysed by chromatography on 'Dowex-50' resin exactly as described by Moore and Stein[3], but at 20° C. instead of 37·5° C., glutamine and asparagine emerge as a single peak. When a blood plasma dialysate is heated to 100° C. at *p*H 6·5 for two hours so as to remove glutamine and then subjected to chromatography by this procedure, a ninhydrin-reacting peak still appears in the glutamine–asparagine range. If this fraction is heated to 100° C. with $2N$ hydrochloric acid for three hours, or incubated at *p*H 7·0 and 30° C. for three hours with 1 ml. of guinea pig serum, which, unlike other mammalian sera contains an asparaginase enzyme[1], then, after chromatography, an equivalent amount of ninhydrin-reacting material appears in the aspartic acid range. When the material in the asparagine range is run through a column of 'Dowex-50' with $0·5N$ hydrochloric acid as eluent it emerges as a peak in the same position as known samples of asparagine; if, on the other hand, the material is first hydrolysed with hydrochloric acid, then peaks emerge in the positions of aspartic acid and ammonia. When the fraction in the asparagine range is deionized and subjected to paper chromatography with aqueous phenol, a single spot is obtained in the position of asparagine; if the material is first hydrolysed with hydrochloric acid a spot is obtained in the position of aspartic acid. The material in the asparagine range when reacting with ninhydrin either in solution or after paper chromatography always gives the delayed colour production which is typical of asparagine.

The concentrations of asparagine in blood plasma samples from four men were 1·4, 1·3, 1·3 and 1·0 mgm./100 ml. The average of the concentrations in five plasma samples from a single goat was 0·95 mgm./100 ml. The concentration of asparagine is thus of the same order as the concentration of many other free amino-acids in plasma.

I am grateful to Dr. D. G. Jamison for his co-operation in obtaining the samples of human blood.

## Some Histochemical Observations on Periodic Acid – Amino-Acid Mechanisms

THE periodic acid Schiff technique has been used histochemically primarily as a means of localizing the 1,2 glycol linkage in tissue sections[1]. It is known, however, that periodic acid is also capable of cleaving the 1,2 hydroxylamino linkage with the production of some aldehyde radicals, and although the exact reaction mechanism is not understood, it is believed by some to react in a somewhat similar manner with a number of amino-acids possessing structurally neither of these linkages. The amino-acids serine and threonine, as well as the "hydroxylysine" of Van Slyke, fall into the first category, whereas cystine, methionine, tryptophane, glycine, alanine, tyrosine, histadine, aspartic and glutamic acids fall into the latter group[2]. This investigation was initiated to study specifically this phase of the periodic acid Schiff mechanism, and although the results were not conclusive, it was felt that a brief description of the experiments might be of interest to others working in this particular field.

Two series of experiments were prepared, one utilizing paraffin-prepared tissue sections from formalin, alcohol and Bouin-fixed blocks of rat, rabbit and human spleen, liver, intestine, cardiac and skeletal muscle, the other using amino-acid impregnated agar and gelatin blocks. These sections and blocks were oxidized in aqueous periodic acid under varying conditions of concentration, time and temperature. The sections were then processed by the McManus periodic acid Schiff technique[3], and the blocks were similarly tested for the presence of aldehyde radicals[4]. The sections, after staining, were compared with routinely stained periodic acid Schiff control sections and with sections stained by the alloxan, ninhydrin, Millon, Axenfeld and xanthoproteic protein localization techniques[5]. It was hoped that in this way correlation could be obtained between the normal protein localization picture and any protein (amino-acid) localizations obtained with intensified periodic acid oxidation. The impregnated blocks were similarly oxidized, and colour development with leucofuchsin was checked against impregnated – unoxidized, unimpregnated – oxidized and unoxidized – unimpregnated control blocks. The sections and blocks were oxidized at 27° C. for periods up to six weeks in 0·5 per cent periodic acid, up to 24 hr. in varying acid concentrations at temperatures up to 60° C., and for periods up to one week at 27° C. in periodic acid concentrations up to 6 per cent.

As previously noted, these experiments were essentially empirical. After 10 min. oxidation in 6 per cent periodic acid at 27° C. or at 60° C. in a 0·5 per cent solution, leucofuchsin coloration was apparent in non-polysaccharide tissue components. A sequence of reaction seemed evident with prolonged oxidation. Initially, the tissue glycol components stained, the intensity increasing with additional oxidation. Non-polysaccharide components became leucofuchsin-positive more slowly, reaching a maximum coloration after several hours oxidation. If oxidation was prolonged, there developed a gradual decrease in coloration in the glycol components, followed more slowly in the non-polysaccharides. After very prolonged oxidation (four days in 0·5 per cent acid at 27° C.) a diffuse non-specific stain was obtained, giving some indication of a gradual destruction of the aldehyde radicals initially produced by the oxidation, such as has been suspected in histochemical chromic acid oxidations. At the peak of their intensity, these non-glycol colorations stained strongly the same tissue components demonstrated by the protein-localization technique, superimposed, of course, on an intense glycol-localization picture. The correlative value of the impregnated blocks was minimal, due to erratic behaviour, although many cases of definite aldehyde production were present after oxidation. Although serine and threonine gave positive coloration after 5 min. in 0·5 per cent acid at 27° C., the results of this phase of the experiment were too non-specific for positive confirmation of periodic acid demonstration of amino-acids in general.

Even though no specific conclusions can be drawn from these experiments, one point is apparent. When tissue carbohydrates are localized by the periodic acid Schiff method, it should be remembered that although a carefully controlled reaction probably reacts only with 1,2 glycols to form aldehyde radicals, this specificity may well be destroyed by excessive oxidation with involvement of amino-acids, especially those containing hydroxylamino linkages. This possibility should be kept in mind when utilizing the periodic acid Schiff procedure.

## Kinetics of Reaction in Ethanol Solution from −80° C. to +20° C.

RATES of reaction in solution have not usually been measured over a range of temperature greater than about 50° C. Measurements over a bigger range would give more accurate values of the energy and entropy of activation, and interesting deviations from the linear Arrhenius relation between log $k$ and $1/T$ might be expected, especially in proton-transfer reactions[1]. We have measured the rate between − 80° C. and + 20° C. of the reaction between ethoxide ion and trinitrotoluene in ethanol, which appears to proceed by a proton transfer:

$$C_6H_2(NO_2)_3CH_3 + EtO^- \rightarrow EtOH + [C_6H_2(NO_2)_3CH_2]^-.$$

The ion produced is coloured and the reaction can be followed photometrically. At room temperature, rates were measured on a rapid-reaction apparatus of the Hartridge–Roughton type using the 'stopped-flow' method[2]; the fastest reaction observed had a half-period of 0·2 sec. At the lower temperatures a thermostat using solid carbon dioxide as refrigerant was employed. The observed velocity constants covered a range of more than 5 powers of 10.

The relation between $\log_{10}k$ and $1/T$ is linear within experimental error over the whole temperature range, as the accompanying table shows. In this table we compare the observed values of the velocity constant $k$, expressed as $k = 10^n k'$, with the values calculated from the equation $k = 1 \cdot 026 \times 10^{12} \exp(-13{,}600/RT)$ mole litre$^{-1}$ sec.$^{-1}$. It will be seen that the deviations are random in direction and not too large compared with the estimated experimental errors.

| $T$ (°C.) | +19·1 | −30·0 | −40·0 | −50·0 | −60·0 | −70·0 | −78·5 |
|---|---|---|---|---|---|---|---|
| $n$ | + 1 | − 1 | − 1 | − 2 | − 2 | − 3 | − 4 |
| $k'$ (calc.) | 6·34 | 5·52 | 1·64 | 4·40 | 1·03 | 2·12 | 4·34 |
| $k'$ (obs.) | 6·30 | 5·61 | 1·64 | 4·42 | 1·00 | 2·18 | 4·58 |
| % diff. | + 0·6 | − 1·6 | + 0·0 | − 0·5 | + 3·0 | − 2·8 | + 5·7 |
| Est. exp. error | ± 3 | ± 1·5 | ± 1 | ± 1 | ± 3 | ± 3 | ± 5 % |

This implies that the energy of activation $E$ is constant within the limits of experimental error, and certainly within 100 cal./mole, at 13,600 cal./mole. A change in the value assumed for $E$ of so little as 40 cal./mole leads to a definite trend in the difference between observed and calculated results. The $A$-factor can be given with corresponding accuracy: $\log_{10} A = 12 \cdot 0 \pm 0 \cdot 1$, with $A$ in sec.$^{-1}$.

The constancy of $E$ implies that the value of $\Delta C_p$ in the expression $E_{(T°C.)} = E_{(-80°C.)} + \Delta C_p(T+80)$ is too low to be detected. A low value of $\Delta C_p$ would be expected for this reaction, since the difference between the specific heats of the transition complex and the reactants will be mainly due to any changes of solvation that occur on forming the transition complex, and these depend largely on the change of charge, which is here zero. Moreover, these changes of solvation would also be reflected in the entropy of activation, and so in an abnormal $A$-factor; and for this reaction $A$ is nearly normal.

This work will be reported in full elsewhere.

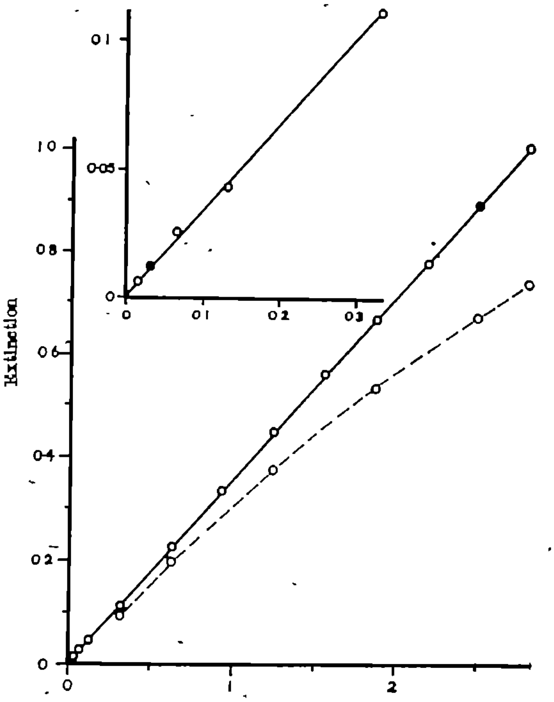
## Determination of Creatinine by the Jaffé Reaction

It has often been stated that the colour-producing reaction between creatinine and alkaline picrate does not obey Beer's law[1–3]. This implies that a calibration graph relating creatinine concentration to light extinction is not a straight line. Curves have been obtained with photoelectric absorptiometers using filters which pass an appreciable band of wave-lengths, for example, 495–550 mμ [4].

Beer's law, however, is only strictly true for monochromatic light[5]. It does not appear to be generally known that an instrument measuring on a very narrow band of wave-lengths gives a linear calibration graph for creatinine, although Borsook and Dubnoff[6] mentioned this fact in describing their method for estimating creatine. The accompanying graph was plotted from readings obtained with a Beckman spectrophotometer for a series of dilutions of a standard solution of creatinine zinc chloride. The modification of the Jaffé reaction published by Bonsnes and Taussky[1] was employed, but the linearity is not peculiar to this particular method. Within the limits of probable volumetric and reading errors, the points fall on a straight line over the range of concentrations which can be read satisfactorily.

The wave-length 520 mμ seems to be the most convenient to use. At longer wave-lengths the sensitivity decreases. At shorter wave-lengths the sensitivity is greater; but this is not an advantage, because at 520 mμ it is already sufficient for the accuracy of the method as a whole. Although the anomalies in light absorption at low concentrations of creatinine reported by Garner[3] suggest that below 515 mμ the relationship would not be linear, similar graphs were in fact obtained at 490 mμ and at 480 mμ, the range of concentrations which could be read being about half as great as at 520 mμ. There was no evidence of any systematic departure from linearity, but apparently fortuitous deviations at low concentrations (see inset graph) became relatively greater, or appeared for the first time, as the wave-length was reduced. The slit-width had to be increased to work at the shorter wave-lengths.

The calibration graph is reproducible if the conditions are kept constant, but this may be difficult to achieve. It has been found that the time for which the colour is allowed to develop before reading is not critical within the limits given by Bonsnes and Taussky, but the temperature of the solutions at the time of reading does have an appreciable effect.



———— Calibration graph for standard solutions of creatinine zinc chloride read with the Beckman spectrophotometer. λ = 520 mμ; slit-width, 0·04 mm. Inset: lower part of the graph drawn on expanded scales. Concentrations refer to creatinine base in the solutions, after diluting but before adding alkaline picrate. The lowest point corresponds to a creatinine concentration about a tenth of that found in a normal serum filtrate. — — —, Calibration curve for the same solutions read with a 'Spekker' absorptiometer, with Ilford 604 filters (nominal band-width 500–540 mμ)

Rather than standardize these and other variables, it is probably simpler to read one or more known solutions with each batch of unknowns, the linearity of the graph then enabling it to be drawn for the conditions prevailing at the time. If the temperature of the solutions alters through heating up while in the instrument, it is advisable either to adopt a standard reading procedure or to warm all the solutions to a suitable temperature beforehand.

Three other practical points may be worth mentioning. Acetone is one of the many substances which give the Jaffé reaction, and it should not be used for drying glassware[7]. Standard creatinine zinc chloride solutions in $N/10$ hydrochloric acid will not keep for more than a few weeks at room temperature[8]: they can be kept under toluene in the refrigerator. Finally, the reagent proportions suggested by Bonsnes and Taussky have the advantage that the alkaline picrate solution does not form a precipitate, and will keep for longer in the mixed form.

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Biochemist (honours science graduate) primarily for research duties in the Geriatric Department of the Sunderland Hospital Group, carried out mainly at the Sunderland General Hospital—The Senior Administrative Medical Officer, Newcastle Regional Hospital Board, Blythswood South, Osborne Road, Newcastle-upon-Tyne 2 (June 27).

Demonstrators (2) in Inorganic Chemistry—The Registrar, King's College, Newcastle-upon-Tyne (June 27).

Principal of Croydon Polytechnic—The Chief Education Officer, Education Office, Katharine Street, Croydon, Surrey (June 27)

Senior Lecturer to teach Metallurgy, a Lecturer to teach Inorganic and Physical Chemistry, and a Lecturer to teach all branches of Physics, at the College of Commerce and Technology—The Director of Education, Leopold Street, Sheffield 1 (June 27).

Assistant (Experimental Officer grade) in the Pathology Department, for routine work on selection and indexing of fruit stocks for virus infection and assistance with experimental work on plant virus diseases—The Secretary, Scottish Horticultural Research Institute, Mylnefield, Invergowrie, Dundee (June 30).

Assistant Principals (2) at the Nigerian Colleges of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges, 15 Victoria Street, London, S.W.1 (June 30).

Lecturer in Applied Chemistry (with honours degree or equivalent, with teaching and industrial or research experience)—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants (June 30).

Lecturer in Physics, and a Lecturer in Genetics, at the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (June 30).

Assistant Lecturer to teach Chemistry to H.N.C. and A.R.I.C. standard, at the Technical College of Monmouthshire, Crumlin—The Director of Education, County Hall, Newport, Mon. (July 1).

Speech Therapist in charge of the Speech Therapy Clinics—The Clerk of the County Council, County Hall, Newport, I. of W. (July 1).

Assistant Lecturer (Grade III) in Physiology (veterinary)—The Registrar and Secretary, The University, Bristol (July 4).

Director—The Secretary, Hill Farming Research Organization, Moredun Institute, Gilmerton, Edinburgh 9 (July 4)

I.C.I. Research Fellowships in Physics, Chemistry, Metallurgy, Engineering or Geology, or in a subject allied to these—The Registrar, University of Wales, University Registry, Cathays Park, Cardiff (July 4).

Lecturer in Philosophy—The Registrar, King's College, Newcastle-upon-Tyne (July 4).

Metallurgist at the Ministry of Supply, London headquarters, to assist in research and development work on metallic materials for aircraft construction and to progress research contracts with Universities, Research Associations, Materials Manufacturers and Aircraft Constructors—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.245/53A (July 4).

Physical Chemist at a Ministry of Supply Research Establishment near Sevenoaks—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.246/53A (July 4).

Lecturer in Bacteriology at the Royal Infirmary, Glasgow—The Secretary of University Court, The University, Glasgow (July 8).

Assistant Agricultural Economists in the Ministry of Agriculture and Fisheries—The Civil Service Commission, Burlington Gardens, London, W.1, quoting 4219/53 (July 9).

Electrical Engineers in Ministry of Supply Experimental Establishments mainly at Malvern, Farnborough, Christchurch and Sevenoaks, for research, development or design in telecommunications, radar, electronics, instrumentation or light electrical measurements—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting D.232/53A (July 10).

Junior Lecturer in Applied Pharmacology and Therapeutics—The Dean, St. Thomas's Hospital Medical School, London, S.E.1 (July 10).

Director (with university degree in agriculture or horticulture) of the States' Experimental Station—The Secretary, Department of Agriculture, 6 Bond Street, St. Helier, Jersey, C.I. (July 11).

Senior Lecturer in Physics at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 15).

Organic Chemist as Research Assistant to the Professor of Medical Chemistry in the John Curtin School of Medical Research, Canberra, for research on the synthesis of new heterocyclic compounds, in particular, pteridines, pyrimidines and pyrazines—The Secretary, London Office of the Australian National University, 27 Russell Square, London, W.C.1 (July 17).

Research Officer (Protein Chemist) (with university honours degree in science with physical—organic—or biochemistry as major subjects and, preferably, research experience in some aspect of protein chemistry) in the Biochemistry Unit of the Wool Textile Research Laboratory, Parkville, Melbourne, to study the chemical composition and reactivity of collagen by application of physical organic or biochemical procedures used in this laboratory for research on wool keratin—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 462/56 (July 18)

Lecturer in Mining (with a university degree in mining and a first-class Colliery Manager's Certificate), and a Demonstrator in Chemical Pathology—The Registrar, The University, Leeds 2 (July 20)

Physicist (honours graduate) to assist in problems related to the treatment of cancer by X-rays, radium and telecobalt—The Secretary and House Governor, Mount Vernon Hospital and Radium Institutes, Northwood, Middx (July 25).

Physicist or Metallurgist (Ph.D., with additional research experience, or equivalent qualifications, are essential) in the Division of Tribophysics of the Commonwealth Scientific and Industrial Research Organization, located at the University of Melbourne, to work with its metal physics group—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 370/81 (July 25).

Director (with the status of Professor) of the newly established Dental Research Unit located in the University of the Witwatersrand Oral and Dental Hospital at Johannesburg—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 31).

Senior Lecturer in Geology (specialized either in stratigraphy and palæontology, or in economic or mining geology), at the University of the Witwatersrand, Johannesburg—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 31).

Lecturers in the Department of Chemistry at University College of Fort Hare, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (August 1).

Lecturer in Prehistory at Auckland University College, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (August 31).

Assistant Professor of Micro-Anatomy (histology and embryology), and an Assistant Professor of Gross Anatomy, in Dalhousie University, Halifax, Nova Scotia—Prof. R. L. DeC. Saunders, c/o Mrs. MacDougall, Upper Slaughter, Cheltenham (September 7).

Demonstrator in Electrical Engineering—Prof. G. F. Tracy, Electrical Building, University of Toronto, Toronto 5, Ont., Canada.

Head of the Department of Mathematics, Cardiff College of Technology and Commerce—The Director of Education, City Hall, Cardiff.

Lecturer (Grade B) in Chemistry (with postgraduate experience in organic or inorganic chemistry)—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11.

Lecturer in the Department of Civil Engineering (with a good honours degree; and practical or research experience in Civil Engineering Hydraulics would be an advantage)—The Secretary and Registrar, The University, Southampton.

Lecturer in Mathematics—The Clerk to the Governors, Mid-Essex Technical College, Market Road, Chelmsford.

Medical Research Officer and a Research Entomologist for the Virus Research Unit in Nigeria, for research on arthropods of medical importance, with particular reference to viral and rickettsial diseases—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.117/14/02.

Physiologist (Scientific Officer or Senior Scientific Officer grade) (with a good honours degree in physiology, or an equivalent qualification, and research experience, preferably involving the perfusion of isolated organs) for research on the physiology of lactation—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, quoting Ref. 53/8.

Professor of Physical Metallurgy—The Head of the Department of Metallurgical Engineering, University of Toronto, Toronto 5, Ont., Canada.

Research Assistant (graduate preferred) in the Department of Inorganic and Physical Chemistry, for the preparation of crystallographic data and the coding of problems for calculations on an electronic computer, and also the actual running of problems through the computer—Prof. E. G. Cox, Chemistry Department, The University, Leeds 2.

Wool Textile Research Council Scholarships (*a*) for work on infra-red spectrometry and (*b*) for work in wool textile technology—The Principal, Technical College, Bradford.

# EDUCATION IN AFRICA

THE recent report of the Parliamentary and Scientific Committee referred to a memorandum from the Colonial Sub-Committee dealing with questions relating to education, agriculture and fisheries, health, forestry and the future of the Colonial Development and Welfare Fund, in which the dependence of Colonial development on the application of modern scientific knowledge in the utilization of natural resources was emphasized. This in turn depends very largely on the technical competence of the indigenous populations and their ability to participate in the process, and it is from this point of view, quite as much as from that of political development, that the study of educational policy and practice in British Tropical Africa recently issued by the Nuffield Foundation and the Colonial Office is of outstanding interest*. It includes the reports of two missions, one, led by Mr. A. L. Binns, to East and Central Africa, and the other, led by Dr. G. B. Jeffery, to West Africa (both of which were financed by the Nuffield Foundation), and the record of the proceedings at the subsequent conference at Cambridge in September 1952, of which Sir Philip Morris was chairman. An analysis of the reports is printed elsewhere in this issue (p. 1134).

The Cambridge conference, at which the Colonial Office and the United Kingdom were represented, consisted mainly of representatives of Colonial territories, chiefly in territorial teams forming an almost complete cross-section of the educational world of British Africa. It was the first occasion for a review of the whole groundwork of education in Colonial territories by those concerting it since 1925, when a general policy for British education in Africa, based upon the work of the Phelps–Stokes Commissions of 1920–21 and 1923–24, was outlined in a "Memorandum on Educational Policy in British Tropical Africa"; it was thus also the culminating event in a long process. Soon after the War, it was realized that, in view of political changes, the extent to which education was becoming rooted in African soil, and the urgency of some problems in educational policy and affairs in Africa, needed careful review and, in many respects, to be thought out afresh.

The approach favoured was more intimate and less formal than that of a Royal Commission. The small groups of experts who, under Mr. Binns's and Dr. Jeffery's leadership, visited Africa were able to initiate in each territory they visited discussions fundamental to the problems of each particular territory. The two reports they prepared formed the basis for the conference discussions, and for that purpose the conference was divided into five groups in which education was discussed from the different vantage points of responsibility and control; the expansion of the educational system; the teaching profession; organization and curriculum; and education and the adult.

---

* African Education: a Study of Educational Policy and Practice in British Tropical Africa. (Produced on behalf of the Nuffield Foundation and the Colonial Office.) Pp. xii+187. (London: Crown Agents for the Colonies, 1953.) 8s. 6d.

The purpose of the conference was not to make policy which should thereafter be imposed upon the territories which were participating, or to fix a common pattern of education on a considerable proportion of a vast continent. It did not seek to pass general resolutions. Its object was to place on record the best views which could be formulated and expressed, so that hereafter those responsible for shaping policy or carrying out educational work should find in the record of the conference opinions and conclusions which had been refined by discussion but which had not been pressed into uniformity. As Mr. Oliver Lyttelton writes in his foreword, the volume poses the problem of education as a challenge and a stimulus to education, and it may well point the way to fresh advances. Moreover, unlike the reports of the Phelps-Stokes Commissions, the conclusions of which were limited to specific territories, the Binns and Jeffery reports present conclusions of general validity even where they were not specifically adopted by the conference.

Throughout the work of the two groups which visited Africa and of the subsequent conference, the method adopted was devised to ensure that the wisdom and experience of those in the field were freely drawn upon in any conclusions which might be reached, and that the processes in which they had participated might have the maximum chance of being relevant and fertile. Certain limitations were, however, placed upon the study. It was limited in the first place to the education of Africans; and higher education, apart from a brief section on university education, so far as affecting the work of the schools and the training of teachers at Makerere College, was omitted, because the ground had already been covered by the Asquith and Elliot reports and because university policy in Africa is under constant review by the Inter-University Council. Furthermore, the development of higher technical education is excluded for similar reasons, and technical education is only considered in connexion with different types of secondary schools and with the needs of industry.

These limitations do not seriously detract from the interest of the report for the scientist as such. With the general approach rather from the point of view of what needs to be done than from that of the available resources and the best means of distributing them, the report is concerned above all with the foundations on which higher education, both at the university- and the technical school-level, can effectively develop. It is concerned, too, with the conditions in which the services of the technician, the technologist and the university graduate can be most effectively utilized and, by implication rather than by precept, it gives a good deal of guidance as to the right priorities to be adopted where means are straitened and some choice of objectives has to be made. The Binns report went so far as to suggest that the churches engaged in educational work in Africa should consider very seriously whether some of their thought, energy and control should not give place to a larger effort in the education of adults, and by this it included the preaching and practice of the Christian religion.

This suggestion that the churches should abandon their thousands of small scattered 'bush' or unaided schools and divert the money and energy thus freed into the channels of adult education was not endorsed by the conference. Nevertheless, it was generally agreed that more could be done to encourage and co-ordinate the work which the churches are doing in the field of informal education, either by association with official training schemes or by participation at the advisory level in national and regional planning. The suggestion, moreover, illustrates two dominant characteristics of both reports and of the subsequent conference discussions, namely, the belief in the necessity of a spiritual basis of all education, and the insistence that a fully comprehensive educational system cannot be developed in isolation from the development of central and local institutions of government.

The Binns report, for example, claims that the situation in Africa amounts to a moral crisis, and suggests that Governments in East and Central Africa should abandon their attitude of neutrality in relation to religion. A public statement on a belief in the necessity for a spiritual basis for education in its widest sense would encourage those already at work and provide inspiration for future development. Both reports, however, agreed in emphasizing the importance of building up moral leadership. The Jeffery report suggests, for example, that it would be a great contribution to progress at this critical stage if those upon whom the responsibility for moral leadership rests could come to a clearer realization of what they have in common in their appreciation of the fundamental human values. "If leaders in all branches of African thought could come together in a united and public testimony of fundamental values they would make a lasting contribution to education on the West Coast."

The Jeffery report urges further that the moral progress of any people depends partly upon the vision and vigour of its prophets, but more upon the example of those men and women who, by reason of consistent and faithful lives, are judged worthy by their fellows. This passage, insisting on the relation between morals and character training, was quoted with approval by one of the study groups at the conference; but the most impressive feature of the conference proceedings is the unanimity of all five study groups in their reports that education must not be purely secular but must have a spiritual basis. This basis can only be assured if religious bodies are formally associated with government bodies in the control of education, and furthermore if training colleges are staffed with those of such high moral character as will fit them to exercise a sound influence upon their students.

This first point, moreover, is linked up with the second, for, as the Jeffery report points out, character is trained in the exercise of responsibility, and in the developing society of West, East or Central Africa to-day, a prime problem is to determine the appropriate measure of responsibility that can be given at any particular moment in relations between child and teacher, between teacher and institution, and between institution and local or central government. To the extent to which this is wisely determined, the effectiveness of education both as an instrument of stability and of change largely depends. It is to be noted, for example, that the Binns report points out that education is inseparable from life, and urges the closest co-operation between the departments of education and agriculture at all levels; in consequence, while it recognizes that scholarship is of first-rate importance, it advocates recruiting an increased number of Europeans for the African education service primarily with the view of their ability to inspire in their pupils a deep and abiding affection for rural life and the things of the countryside. All practical work in the schools, moreover, should have a real meaning to the pupils, and should never be allowed to become mechanical drudgery.

The vision of education which inspires these reports is that of the united concern of a people for the right upbringing of its children and the improvement of its national life. Success depends upon the co-operation of parents, teachers, administrators, leaders in public affairs and of all who care for the future of their country. An essential element in it is to provide full opportunities for creative activity; and to the extent to which it inculcates also that respect for truth, which is the characteristic educational value of science, it can play an essential part in developing the sense of common citizenship—a sense which experience has already shown is developed not so much through political institutions themselves as from participation in some kind of leisure-time education or activity that exacts loyalty and demands enthusiastic endeavour. What is sought is, in effect, a more liberal education for Africans based on their own African environment and on their own way of life—an education, as the Binns report puts it, designed to enable Africans to understand their environment and to lead the most complete life that is possible in it.

The emphasis on the spiritual basis of education is strongly reflected in all that is said about the training of teachers. The importance of quality here is stressed as much as, if not more than, the need for keeping education keyed with the traditions and needs of the people concerned. The supply of teachers lies at the very heart of the educational problems of the West African coast regions; but the Jeffery report nevertheless maintains that raising the educational standard for admission to training is one of the most urgent educational needs. An increase in the number of really good teachers should be the spearhead of educational progress, and there is no single aim in which effort could be concentrated to greater advantage.

This reflects the conclusion of Lord Hailey's "African Survey", that the most pressing need in popular education in British territories is the improvement of standards of teaching and better means of control. The Binns report likewise suggests that in the teachers' training colleges is to be found the remedy for many of the serious weaknesses in African education at present. In the teachers' training colleges, as well as in schools, it suggests, a moral code should be inculcated by the active formulation of good habits and the development of a strong community life. The staffs of training colleges should be selected as examples of what their students should become, and morality should be presented to students as a matter of principle and of service to the community, while great attention should be paid to fostering "initiative and responsibility". The recruitment, conditions of service and training of teachers are discussed at some length in this report, and were also considered by one of the five study groups at the subsequent conference; nor was there difficulty in reaching agreement on the main aspects of policy.

The points which received general support were not, in fact, new, and what is most noteworthy about them is rather the sense that they are essential, and that if governments really wish to encourage the development of education they must break down whatever obstacles have hitherto prevented action along the lines indicated. Some of these points, notably that about continuity of staffing, are peculiarly matters for government action: attention is directed throughout this report to the harm which is done when teachers are moved to suit the administrative convenience of an education service without regard to the effect on the teacher or the institution concerned. Besides this, there is an equally noteworthy sense of the way in which the training of teachers should be in line with the needs and the development of the community. For example, it is recognized that any distinctive African contribution to the world must be based on the African's love and respect for the mental inheritance of his people, much of which is enshrined in language. There is warning against the danger of discarding good values from tribal life, while taking from Western culture, not its spiritual strength but its materialistic weakness. With the insistence on the necessity of a good general education as a basis for successful technical education goes that on the need for a close connexion between technical education and industry. Likewise, it is recommended that technological education should be developed to keep pace with industrial expansion and to enable Africans to make their maximum contribution as skilled workers in accordance with the opportunities available in each area; and in view of the great importance of agriculture in African life, agriculture should be strongly represented both in teaching and research at the university-level. Attention is also directed to the practical help which could be given to educational policy and practice by such university studies as those at Makerere College into the causes of wastage in the schools, or at the Institute of Education into intelligence testing as applied to East Africa.

In all this is implicit the belief that administrative advance must come to terms with political realities. If Africans are to find adequate expression for their new hopes and aspirations, they must have opportunities for serving the public interests of their country in their immediate communities. Real service, moreover, needs an element of responsibility, and participation in local affairs is both a present service and a preparation for the larger services which the future will require of them. Here there is also recognized the danger of a dichotomy between the literate young and illiterate elders. Some means must be found of ensuring that some at least of the older generation are carried along with the general movement.

This is one reason for the report's emphasis on what it terms 'informal' or adult education, rather than mass education, though the methods used may be both formal and informal; and its importance appears again in the report recently prepared by the Hansard Society* on problems involved in developing parliamentary institutions in Colonial territories. The other main reason for such emphasis appears in regard to finance. Both the Binns and the Jeffery reports urge that the proportion of government expenditure which is devoted to education requires increasing; but the study group at the conference at Cambridge which considered the expansion of the educational system paid little attention to the question of finance, and the conference as a whole did not appear to come to grips with the real issues here. It was left for one of the speakers in the discussion to suggest that in present circumstances the expansion of education is an emergency problem and must be treated on an emergency basis. Education should not be regarded merely as one among a number of services which compete for whatever share of the revenue remains after providing for justice, communications, administration, the national debt and other essentials.

Perhaps the great value of the whole report on African education may lie in its demonstration that education is an essential service and that, as the Binns report points out, "if it is deprived of the means to do its work well, all the departments will suffer". If education is to receive not merely its present ten or twelve per cent of the revenue but a greatly increased allocation, this point must be clearly understood both by the Government itself and also by the community on whose support that government rests. To the extent to which educational developments are supported from Colonial Development and Welfare Funds, it is important that public opinion in Great Britain should also understand what is involved. It is, however, of increasing importance that in those territories in which Africans themselves are associated with administration and government, there should be a clear understanding of the whole nature of educational policy and its relation to the needs of the community, and of the effort and sacrifices which are required to pursue consistently a policy of expansion which will meet African needs.

There is much else of great interest in this report. It is constructive as well as critical. It puts its finger firmly, as did Dr. G. B. Jeffery in an earlier report, on the weaknesses and dangers of the examination system, and it shows very clearly how valuable is the help which the British universities and individual teachers from Great Britain could give in meeting African needs in this field. It is as clear as from the Hansard Society's report already mentioned that, unless such help is forthcoming, and unless the governments concerned face the problems set out here with determination and a sense of urgency, there is little hope that parliamentary institutions will either develop or function in the Colonial territories of Africa. Political progress cannot be isolated from economic, social, cultural and spiritual progress. Even in such a comparatively advanced democracy as Britain, a primary lesson of a satisfying education, namely, that there are no civic rights without civic duties, and that liberty can only be earned, has been imperfectly learned. Educational policy and practice in Africa are of supreme importance, because their adequacy and efficacy determine both the standards of administration and the effectiveness of whatever forms of democratic institutions may be adopted, the functioning of the whole organization of government, the reality of co-operation in the tasks of government at local and at central levels, and equally the pace of economic and social development upon which the welfare of the society depends. The report on African education sounds the right note of urgency and indicates practical steps to be taken. That from the Hansard Society does not merely put the issue in its true perspective; it also indicates substantial reasons for believing that the parliamentary system may yet succeed in the Colonial world, and that the educational effort which Britain as well as the Colonial peoples is summoned to make in Africa may be undertaken with confidence.

# PLASTICITY UNDER PRESSURE

## Studies in Large Plastic Flow and Fracture

With Special Emphasis on the Effects of Hydrostatic Pressure. By Prof. P. W. Bridgman. (Metallurgy and Metallurgical Engineering Series.) Pp. x+362. (London: McGraw-Hill Publishing Co., Ltd., 1952.) 72s. 6d.

DURING the past twelve years or so, Prof. P. W. Bridgman has been making experiments on the plastic flow and fracture of metals, and other solids, when these are subjected to large hydrostatic pressures (for example, 450,000 lb./sq. in.) superposed on the stress system that actually causes flow and failure. The starting-point for the work was his discovery, just before the Second World War, that the ductility of ordinary steels increases enormously in the presence of such high pressures, the reason for this being of course that, while the hydrostatic stress squeezes the atoms together, so that fractures cannot start inside the body, it does not stop the atoms sliding past each other. It appeared likely that this discovery would shed light on the unusual behaviour of armour plate under high-speed penetration, particularly since it was known that the stresses developed around the nose of a projectile during penetration are of a similar magnitude; and these considerations led Prof. Bridgman to begin a systematic investigation of the effect, under the sponsorship of the United States National Defence Research Committee and of the Watertown Arsenal.

* Problems of Parliamentary Government in Colonies: a Report prepared by the Hansard Society on some of the Problems involved in developing Parliamentary Institutions in Colonial Territories. Pp. x+154. (London: Hansard Society, 1953.) 12s. net.

Much of this work was written up during the War in government reports. These have now been declared available to the public, but still remain largely unknown. As for the rest of the work, only a part of it has been recorded and published until now. A result of this poor publicity is that some of the experiments have already been duplicated by other people, unaware of their existence. To remedy this situation, Prof. Bridgman has written the present book, in which he has collected together the work into a coherent and easily accessible form.

It is an unusual book, not only for what it contains but also for how it is written. Presented in a very personal style, in which the first person singular is often used, it amounts almost to a highly polished log-book of the author's researches. In places there are accounts of historical details, not only of the ups and downs of particular experiments, but also of the negotiations surrounding their planning and publication. The general reader may feel that neither of these latter is meant for him, that the experimental details are only for those about to make similar researches, and that the negotiations have been brought in only because the author wished certain facts about them to be placed on record.

To set against the tedium of these passages, the general story of the experiments makes fascinating reading. Chapters are included on the tension of steel under hydrostatic pressure, on similar experiments with other metals and various mineral substances normally considered brittle, and on two-dimensional tension, compression, brinell indentation, punching, wire drawing and extrusion, all under hydrostatic pressure. The effect of external pressure on cavities is studied with several materials, and various other experiments are described dealing with large strains in one-dimensional and two-dimensional compression, and in torsion and shear. Finally, an account is given of the effects of prior deformation under one type of stress system on subsequent behaviour under other types. Theoretical analyses of stress distribution, including that at the neck of a tensile specimen, are made at various places throughout the text, and in these the author's exceptional physical intuition guides him surely over otherwise hair-raising routes to some very reasonable solutions.

Only a few of the many interesting points can be mentioned here. Chapter 4 describes an extremely ingenious method of making tensile tests, under hydrostatic pressure, which dispenses completely with shoulders at the ends of the gauge-length and so avoids their associated stress concentrations; this is essential when making tensile tests on brittle substances. In Chapter 5 it is shown that, under high compressive stresses, single crystals of alumina deform plastically on slip planes; the appearance of the deformed crystal in the photograph of Fig. 62 is strikingly reminiscent of that of a compressed zinc crystal that has been deformed by kinking. The great ductility which can be obtained under high hydrostatic pressures is demonstrated in numerous ways. One of the most interesting of these is in wire-drawing, where reductions in diameter and intensities of work-hardening can be achieved that far surpass ordinary experience; there is surely the basis of an important industrial process here.

To conclude, this is a book which will undoubtedly prove most valuable to those concerned with the mechanical properties of solids under extreme pressure, whether in a laboratory, a forge, a mineshaft or an armoured fighting vehicle. A. H. COTTRELL

# FOURIER SYNTHESIS OF CRYSTAL STRUCTURE

## Fouriersynthese von Kristallen und ihre Anwendung in der Chemie

Von Prof. Werner Nowacki. (Lehrbücher und Monographien aus dem Gebiete der exakten Wissenschaften, Chemische Reihe, Band 6.) Pp. 237. (Basel: Verlag Birkhäuser, 1952.) 34.30 Swiss francs.

THIS book, on the use of Fourier series in crystal structure analysis, is the outcome of lectures given by Prof. W. Nowacki to advanced students during the summer and winter sessions of 1948–49. The author presumes some knowledge of crystal structure analysis on the part of the reader, thus making it an advanced text-book on the subject. Although the information given is not more recent than 1949, there are copious lists of references to each section, which makes it an excellent reference book to the teacher, the research worker and the student in X-ray crystallography.

The book is divided into two parts, each of which might be brought under the more general headings of structure determination and technical aids for computation, respectively. The first seven sections of Chapter 1 are taken up by an introduction to Fourier syntheses and, by using Lonsdale's "Tables", the author derives the structure factors and the electron density expressions for the space groups $P2_1/c$, $P2_12_12_1$ and $Pna$. The accuracy of determining atomic positions is next taken up in relation to errors arising from the termination of series effects with appropriate corrections. The author, however, is not in favour of applying an artificial temperature factor to the observed $F$-values since, as he rightly points out, such corrections tend to introduce more errors than those they were intended to eliminate—namely, the diffraction effects of an abruptly terminated series. A discussion follows on methods of refinement which include Bragg–Lipson structure-factor graphs, molecular transforms, differential synthesis, and methods of least squares and steepest descent. The last two sections of the chapter, which should have appeared earlier, form the basis of structure analysis. Determination of absolute $|F|$-values are discussed, including the use of Wilson's very useful statistical method, and lastly a brief survey is carried out of the more usual methods of phase angle determination—namely, trial and error methods, the use of isomorphous replacements and the heavy atom technique, the use of Harker–Kasper inequalities, Buerger's implication diagrams and the 'fly's eye'.

Part 1 of the book is concluded by a detailed treatment of Patterson syntheses, with sections dealing with its extensions in the form of Harker and Buerger syntheses, respectively. A full description is given of space-group determination using Buerger syntheses, and Table 19, incorporated as a booklet, gives the hundred and twenty extinction groups useful for space-group determination. These two chapters form the basis of this book. It is rather unfortunate that it appeared at a time when some significant advances were being made in the technique of structure determination, three examples of which may be quoted. First, Wilson's statistical methods used as aids in space-group determination are now in general use and possibly supersede the methods suggested by Buerger syntheses. Secondly, $(F_o - F_c)$ syntheses and differential syntheses are likely to be used to a greater extent for the accurate location of atomic centres rather than the method of steepest descents. Thirdly, Lipson and Taylor's development of optical methods for viewing molecular transforms and for the determination of phases has given a new turn to our concepts of structure determination. Nevertheless, these recent developments do not in any way diminish the usefulness of this book.

The second part of the book deals with methods of calculating Fourier series and structure factors. There is a full description of the Beevers–Lipson method, and brief references are made to other electro-mechanical aids, of which the Hollerith punched-card technique has come to be widely used.

The book as a whole is well produced, well indexed and well referenced. It is to be hoped that Prof. Nowacki will bring out a second edition in which are incorporated the more recent advances, thus adding to the merit of an already useful book which can be fully recommended. C. H. Carlisle

# PHYSICS MONOGRAPHS FOR STUDENTS

### Fundamentals of Thermometry

By J. A. Hall. Pp. 48.

### Practical Thermometry

By J. A. Hall. Pp. 51.

### Soft Magnetic Materials used in Industry

By A. E. DeBarr. Pp. 62.

### The Magnetic Circuit

Powder Cores, Ferrites, Permanent Magnet Materials, and Miscellaneous Magnetic Materials. By A. E. DeBarr. Pp. 62. (Monographs for Students.) London: Institute of Physics, 1953. 5s. each.

THE Institute of Physics by its various publications, particularly the Physics in Industry series of monographs and the monthly journal, the *British Journal of Applied Physics*, has greatly advanced the study and development of applied physics and provides the industrial physicist and research worker with up-to-date factual information. The proper training of applied physicists, a matter of paramount importance, has also occupied the attention of the Institute, and it issues National Certificates in applied physics jointly with the Ministry of Education and the Scottish Education Department. However, the usual text-books on physics are not primarily concerned with the practical applications and with instruments, and thus the Institute has started to publish a new series of "Monographs for Students" which have been specially written for general reading by students attending courses for the Higher National Certificate in applied physics; these books constitute a valuable and important contribution to the literature of applied physics, and a stimulus and aid to the student.

The first four volumes in this series are remarkable for their excellence in content and production. The graphs are particularly clear and easy to read, though some diagrams have suffered from over-reduction. "Fundamentals of Thermometry" and "Practical Thermometry" are companion volumes: in the former attention is concentrated on the International Temperature Scale, and in the latter the instruments and techniques described are largely those recommended by, or used at, the National Physical Laboratory, where the author is a senior principal scientific officer and is actively engaged in the testing and development of temperature-measuring instruments. "Soft Magnetic Materials used in Industry" and "The Magnetic Circuit" are also companion volumes, and, in case the reader may be misled by these titles, it is perhaps well to add that the physical basis of, and introduction to, magnetic properties is given in the first of these two monographs, while in the other are details of powder cores, ferrites and other magnet materials. The domain theory of ferromagnetism, antiferromagnetism and ferrimagnetism all receive adequate treatment.

The monographs are short but handy booklets in stiff paper covers; they should have a wide circulation. S. Weintroub

# D.C. ANALOGUE COMPUTERS

### Electronic Analog Computers (D–C Analog Computers)

By Dr. Granino A. Korn and Theresa M. Korn. Pp. xv+378. (London: McGraw-Hill Publishing Co., Ltd., 1952.) 59s. 6d.

THIS book is concerned with electronic analogue computers of one class only, namely, those in which the variables are represented by voltages and in which the circuits are direct-coupled throughout. The authors are primarily concerned with the use of such machines for solving sets of ordinary differential equations in which time can be used for representing the independent variable. There is a section dealing with machines for solving sets of simultaneous algebraic equations, but this subject is not dealt with at length.

The authors are much too concerned with practical details of design to attempt to define the field in which D.C. analogue computers are of use, although they wax enthusiastic on p. 3 about a computer wired up from scrap parts on a 'bread-board' in two hours at negligible cost and ready to furnish needed information with fair accuracy. But it is clear from the book that the authors have been primarily concerned with the use of analogue computers in aircraft design, both for investigating the behaviour of servo systems, non-linear damped oscillators, etc., and also as simulators, for example, in the testing of autopilots when a computer can be used to simulate the behaviour of an aircraft. In these applications the main drawback of analogue computers—poor and uncertain accuracy which falls almost to nothing when the magnitude of the variable considered changes by a large factor—is not greatly in evidence. This is partly because the results are interpreted by engineers who understand the working of the computer and know when the results given are likely to be trustworthy. I am not sure whether the authors would agree that analogue computers are less useful for dealing with differential equations which arise in more mathematical contexts—for example, in theoretical physics.

The greater part of the book is concerned with theoretical and practical aspects of the design of D.C. amplifiers, integrators, differentiators, multipliers, function generators and other computing circuits. This part of the book is admirably practical and should be of use to anyone concerned with the design of electronic devices which include computing elements. The section on the choice of scale factors should similarly be of interest to users of analogue computers. M. V. Wilkes

### Semimicro Qualitative Analysis

By Prof. Paul Arthur and Prof. Otto M. Smith. (International Chemical Series.) Third edition. Pp. xi+285. (London: McGraw-Hill Publishing Co., Ltd., 1952.) 34*s*.

THIS book is intended to provide an elementary course in inorganic qualitative analysis on the semi-micro scale, covering the commoner cations and anions, but excluding separations in presence of phosphate. Ten chapters, roughly half of the text, give an outline of the theory involved, each being followed by a series of questions for the student, and including, where relevant, typical worked examples. The remainder gives a survey of experimental technique, clearly illustrated by diagrams, followed by analytical schemes for cations and anions. Each tabular scheme is preceded by a brief general survey of the reactions of the ions included, and followed by a series of notes on the experimental procedures.

The analytical schemes for the cations follow mainly the classical pattern, but a useful alternative method for the analysis of the iron group, based on a modified Ford–Williams separation of manganese and chromium, is given. This should minimize adsorption errors such as occur in the usual hydroxide–sulphide method for this group. The tabular schemes are clearly set out, and the accompanying notes cover most of the difficulties likely to be met with by students without overloading the text. Confirmatory tests for particular ions are based, as they should be, mainly on the correct carrying out of the separation procedures, but a short section lists alternative special reagents for use in doubtful cases.

The practical section is evidently based on laboratory experience of the methods described in the text, and this, together with the appended notes, makes the book a reliable introduction to the theory and practice of qualitative analysis. J. A. Mair

### Bibliographie des langues aymará et kičua

Par Paul Rivet et Georges de Créqui-Montfort. (Université de Paris: Travaux et Mémoires de l'Institut d'Ethnologie, Tome 51.) Vol. 1 (1540–1875); pp. xlii+500; 3,200 francs. Vol. 2 (1876–1915); pp. v+656; 3,500 francs. (Paris: Institut d'Ethnologie, 1951–52.)

THESE two volumes, which are a product of forty years of work, comprise a list, with short critical notes on each item, of practically everything which was printed in Quichua and Aymara from the Spanish Conquest down to 1915; and, although the authors invite additions and corrections, it is unlikely that they have missed anything of importance. The title pages of a good many of the more important works are reproduced in facsimile, and an index is promised but has not yet appeared, so it will presumably follow in a subsequent volume.

The introductory chapter is brief, and, besides describing the objects and scope of the work, it sets the stage by giving a short account of what the authors conceive to have been the general linguistic situation during the time of the Incas. In the course of this they repeat some statements with which many linguists disagree, but they themselves stress the immature state of linguistic studies of South America, so this need cause no surprise. Most of the material is connected with the evangelization and religious instruction of the Indians, and in the nature of things little can come from native sources, so a relatively large proportion of this chapter is devoted to a discussion of the original MSS. of the native drama Ollantay.

Having heard Prof. P. Rivet introduce and present these volumes to two recent international congresses —the Peruvianists in Lima, and the Americanists in Cambridge—I can testify to the enthusiastic reception which they have already received from many scholars, and have no doubt that they will be equally warmly welcomed by all who are concerned with the historical and linguistic study of South America.

G. H. S. Bushnell

### Automatic and Manual Control

Papers contributed to the Conference at Cranfield, 1951. Pp. xi+584. (London: Butterworths Scientific Publications, Ltd., 1952.) 50*s*. net.

EACH paper in this volume is a contribution to fundamental design technique, and as such would merit scientific publication, in one form or another, in the usual way. In considering a symposium of such papers, however, the questions which arise are: Is the publication of the collection, as a whole, worth while, and does it fulfil the objects which the editorial committee set itself? According to the preface, the volume is intended as a work of reference for those engaged in control equipment design, and also as a book which might valuably assist those possessing a general background knowledge to branch out into more specialist fields. It must suffer, as a work of reference, by its very structure, which makes it impossible to use as a normal referenced text-book; nor can it be particularly comprehensive, as much of the basis of design technique has to be taken for granted. To offset this, one has the advantage of the direct research experience of specialists, much of the material being a model of presentation, logical in sequence, lucid and well illustrated. Although a point has been made of covering specially the mathematical techniques employed in the theory, and though wide in its applied interests, the work must prove a difficult one for students. This does not detract from its inherent value, and in the class of published symposia it must certainly take a very high place. A. J. Kennedy

### King Solomon's Ring

New Light on Animal Ways. By Konrad Z. Lorenz. Translated from the German by Marjorie Kerr Wilson. Pp. xxi+202. (London: Methuen and Co., Ltd., 1952.) 15*s*. net.

WELL known in scientific circles for his elaboration of the 'releaser' and 'imprinting' mechanisms in animals, Dr. Konrad Lorenz is now seeking to interest a bigger audience in his life's work. In "King Solomon's Ring" he tells of insects, fishes, ravens, geese, jackdaws and dogs with rare insight arising out of great creative powers allied to direct observations often carried out in most painful and trying circumstances the like of which few naturalists have experienced. As a result, Lorenz has stories to tell which, because of their very truth, grip the reader in wonder and admiration. The accounts themselves are embellished by a style of writing which, while never less than scientific, is at once lucid and simple, as well as amusing thumb-nail sketches which have been contributed by the author himself. If the book has any blemish, it is that the remarkably fine chapter on jackdaws deserves a volume to itself. In the meantime, one gratefully welcomes this book which, of its kind, has known no peer for many a year. T. H. H.

# STOCK-TAKING ON AFRICAN EDUCATION

DURING the ten years of its existence, the Nuffield Foundation has made a signal contribution to the welfare of the British Commonwealth and Empire. Through its fellowship and scholarship schemes many promising young men and women have been assisted to travel abroad from their own countries, to improve their knowledge and enrich their experience, so that they may return home more capable of serving their peoples. During the Foundation's first five-year period, its main Colonial policy was to provide material and social aids to ensure that selected scholars obtained the qualifications which the Colonial Office deemed necessary for the specific posts in government service to which the scholars aspired. On their side, the Colonial administrations undertook to absorb all successful scholars. They did not always honour this pledge. So, it is particularly gratifying to note the successful co-operation between the Nuffield Foundation and the Colonial Office which has resulted in the document under review*.

The report on African education is in three parts, each representing a milestone in an endeavour which lasted two years. The first section is a record of the discussions and recommendations of the West Africa Study Group which spent the last six months of the year 1951 visiting the territories of Gambia, Sierra Leone, Gold Coast and Nigeria. The second part of the book deals with the deliberations of the team of educational experts which visited East and Central Africa at the same time. The work of these two study-groups culminated in a conference which was held in King's College, Cambridge, last September. The proceedings of that conference are chronicled in the third part.

Not since the Phelps-Stokes Commissions of the early twenties has so much thought been given to the vital matters of Colonial education, or so many illustrious educationists been involved in the process. The East and Central African group consisted of Mr. A. L. Binns (chairman), chief educational officer for the Lancashire County Council; Prof. B. A. Fletcher, director of the University of Bristol Institute of Education; and Miss F. H. Gwilliam, assistant educational adviser to the Secretary of State. The West African group consisted of Dr. G. B. Jeffery (chairman), director of the London University Institute of Education; Mr. F. T. Arnold, H.M. staff inspector for secondary schools; Dr. Josephine Macalister Brew, educational adviser to the National Association of Girls' Clubs and Mixed Clubs; and Mr. E. W. Woodhead, county education officer for the Kent County Council. The meetings at Cambridge were held under the chairmanship of Sir Philip Morris, vice-chancellor of the University of Bristol, who, as Mr. Oliver Lyttelton states in his foreword to this report, must be credited with a large share of the success achieved and the goodwill shared. A large delegation from the Colonial Office attended the Cambridge conference as visitors, and each of the Colonies and Protectorates affected sent official representatives and unofficial observers. Those from West Africa falling in the latter category were mainly politicians holding the newly created portfolios in education, and the value of their contribution must have lain in their immense goodwill and large-hearted co-operation.

An interesting feature of the conference at King's College was the small number of formal lectures delivered; and those that were given came from a strange combination of authoritative sources: Prof. Margaret Read, professor of education and head of the Department of Education in Tropical Areas, University of London, referred to world-wide implications of the African education movement; Prof. B. W. Bigelow, Columbia University, New York, stressed the need for co-operative action in solving the educational problems of Africa; and Sir John Maud, permanent secretary to the Ministry of Education, outlined the value of the British system of separating questions of party politics from those which are purely educational.

The terms of reference of the two teams of educationists which visited Africa in 1951 precluded them from considering in detail not only the political influences at work in the territories under study, but also university work and development. Higher technical education was also not to be emphasized. The points covered included teacher training, elementary and secondary education, the relationship between government and voluntary agencies, financing educational projects, and the curriculum. These aspects were emphasized in the 'working paper' which was drawn up by the Advisory Committee on Education in the Colonies, and dispatched to East, West and Central Africa, prior to the visits of the experts.

The Jeffery and the Binns reports are different in a number of fundamental ways; in one the emphasis is on broad principles, with occasional references to relevant details. The other consists of innumerable tiny dots placed together as in a half-tone reproduction of a photograph. Of course, the issues were not the same and could not possibly have been placed in the same perspective.

The East Africa group was faced with all the complexities of life in a British territory where Anglo-Saxons have made their permanent homes, side by side with Asiatics and Africans. Their hands were further manacled by being told to avoid educational matters appertaining to Europeans and Asiatics. Since Kenya, Uganda, Northern Rhodesia, Tanganyika and Nyasaland are no longer African lands, as such, but have been declared to be places where a life of partnership must be sought, as between members of the different races, any broad study of educational policy must take into consideration the different practices in vogue, and place them in a composite setting which alone can truly reflect the *status quo*. It is the absence of such an approach that makes the Binns report so frustrating to read.

The main thesis of the East Africa Study Group would appear to be that Africa is an agricultural country, and we must do our best to make it remain so. We must educate the Africans for life 'on the land'. So far as possible, the African must be made to pay directly for this education, in fees as well as in taxes. It does not matter if the central government spends several times as much money on European education than on his. It does not matter if European agriculture depends for its productivity on African labour.

If this is accepted as the line of argument, then the recommendations of the Binns report begin to make sense—the first phase of primary education should be curtailed from six years, as it is now, to four years; and the aim should be to give 50 per cent of all children of school-age four years schooling in the local vernacular. Swahili, which is the only indigenous lingua franca, should be discontinued in schools, and its place taken by relatively unknown local tribal languages. It should be the aim of the educational authorities to provide a further four-year course for 10 per cent of the school-age population, and four years secondary schooling for 2 per cent of all the children who should be at school. It is preferable to site African schools not too near the towns. European supervisors should be placed over trained African teachers, for the time being. The prerequisite of a university degree for highly paid European teachers should sometimes be waived to make it easier to recruit men with an agricultural bent, who, by their presence in African schools, would inspire the 'natives' to become good farming folk.

---

* African Education: a Study of Educational Policy and Practice in British Tropical Africa. (Produced on behalf of the Nuffield Foundation and the Colonial Office.) Pp. xii+187. (London: Crown Agents for the Colonies, 1953.) 8s. 6d.

However, the report of Mr. Binns and his colleagues is valuable on account of the stress it lays on (*a*) the importance of research into those aspects, for example, wastage, of African education which now appear baffling; (*b*) founding teacher colleges of 100–200 students, with practising schools attached; (*c*) the encouragement of female education by relieving transport difficulties; (*d*) providing bedsheets, spoons, lavatories, and similar elements of prime necessity in boarding schools; (*e*) making teachers competent to teach Africans English in the intermediate and secondary schools; (*f*) erecting a suitable moral and religious basis to all education. Perhaps the most important—certainly the most wise—utterance in the entire report is the following: "The ideal school, if it were acceptable to parents, would be an interracial school. There are no insurmountable practical difficulties in the way of interracial education at any stage, but there are many difficulties in men's minds. Initiatives in this direction must therefore be the pioneer efforts of individuals who feel a call to experiment in this field . . . and because the task of government is eased as racial tensions are eased, such initiatives should receive moral and financial aid from the Government". One cannot help wondering why this does not appear in the official recommendations of the group.

Dr. Jeffery and his co-workers, who are convinced that "the potentialities of the West African have been demonstrated by actual achievement", had an easier task. The Phelps-Stokes Commission of 1920 had a Gold Coast member, Dr. Aggrey, on it; and the implementation of its recommendations have probably been pursued much farther in West Africa than elsewhere.

But there are still many problems awaiting solution. For example, the group expressed its anxiety over the possibility of the local governments taking over responsibility of recurrent expenditure for education when the Colonial Development and Welfare Funds come to an end. The question of raising capital for the great educational expansion that is called for is another cause of worry for those responsible for educational development in West Africa. About a third of the probable annual expenditure of £3 million by the Nigerian Government will be absorbed by higher education. Is this proportion too high, in view of the great need for extending the frontiers of elementary education in the rural areas? Is it wise, at this critical stage, to build up an extravagant medical school to train only a handful of clinicians annually?

On the perennial question of the relationship between voluntary and governmental agencies, the commission agrees that a functional amicable relationship is gradually being built up in West Africa. The system whereby government grants voluntary bodies financial aid in the running of their schools is commended here, as in East Africa. The group records a consensus of informed African opinion that an entirely secular education is undesirable; but does not insist that the religious basis should be Christian. West Africa has a considerable Moslem population, and there are other religious groups.

Although the Jeffery committee commends the "Accelerated Development Plan for Education in the Gold Coast" on both educational and administrative grounds, the bottleneck may prove to be the recruitment of staff. It is the same problem all over again. African graduates do not take up the teaching profession because the prospects of promotion are not great. Besides, expatriate staff receive much better emoluments, even under the African Governments which are emerging on the West Coast.

The Cambridge conference reconsidered all these questions under the following heads: *A*, Responsibility and Control; *B*, Expansion of the Educational System; *C*, Teaching Profession; *D*, Organization and the Curriculum; *E*, Education and the Adult. The reports of the five study-groups of the conference and the plenary discussions on them are printed in this volume in an edited form. Mr. W. E. Ward, editor of the Colonial Office journal *Overseas Education*, in his private capacity put the material together. On the whole, the conference appears to have favoured the Jeffery approach rather than the Binns; but many a reader will feel regret that the names of the speakers have been omitted from the dialogues.

As Sir Philip Morris states in his epilogue to the conference, its chief purpose was, obviously, in human relations. The whole purpose of education is in human relations; for, in the language of the West African study-group, "education is the complex of actions and reactions between persons by which a nation prepares itself for its future by the dissemination of knowledge and skills and valid ideas of human dignity and fellowship". OLUMBE BASSIR

# NUCLEAR PARTICLE LABORATORY AT QUEEN MARY COLLEGE, LONDON

THE inauguration on June 23 of the Nuclear Particle Laboratory at Queen Mary College, University of London, marks what is probably the first occasion on which applied nuclear physics has been officially instituted in Great Britain as part of the undergraduate engineer's education. The laboratory has, however, a dual function to fulfil. In addition to the provision of practical work for undergraduates in the field best described as nucleonics, it also makes available facilities for research work relating to accelerating machines and gas discharges, where high-voltage electrical engineering, electronics, and nucleonics have a common frontier.

Taking the undergraduate work first, the subject designated 'nuclear energy' is offered to third-year mechanical and electrical engineers as one of a number of options from which part of the final year's work is selected. (This is now usual in schools of engineering in North America.) The course is therefore somewhat superficial compared to the other aspects of engineering, which receive three years study. However, it would be wrong to allow greater specialization at this stage in the new subject, even though it may be expected to develop extensively during the active life of the present undergraduate population. The lectures are based mainly on the recently declassified information on nuclear reactor design, but also on general aspects of nuclear physics related to engineering. To obtain a suitable laboratory course to support such lectures, use is made of artificial radioactive sources, and particularly, antimony–beryllium neutron sources. These enable measuring techniques to be studied, which relate directly to engineering uses of radioisotopes as well as providing substance to some aspects of reactor theory, such as neutron distribution theory and calculations relating to cross-sections. It is hoped that it will eventually be possible to extend these experiments by the use of material enriched in fissile components. The whole subject is of general interest to engineers, as quite apart from the practical uses for which nuclear energy will become available, its development is an outstanding example of the logical and scientific processes by which the formulæ of theoretical physics can eventually be translated into engineering reality.

The research facilities offered by the Nuclear Particle Laboratory centre around the high-voltage equipment, which is not yet complete. A 1-MV. electrostatic generator has been in use, however, for examination of discharges in continuously evacuated systems, and similar work has been carried out at 100–200 kV. using rectifier sets. An impulse generator for 1 MV. shortly to be finished will at first be used on the same programme, though it is planned to develop, from this, a high-intensity electron accelerator. Interest has so far tended to be concentrated on the discharge phenomena at residual gas pressures, because this is often a practical engineering limitation in the design of accelerators, particularly D.C. accelerators of the electrostatic type. It has been found that preliminary discharges are obtained in such systems with characteristics which have not previously been investigated in any detail. Further apparatus in use includes a 5-MV. single impulse air-cored betatron which can be employed to give short X-ray impulses at higher voltages; but the intensity is, of course, much lower. An electron microscope is also in operation, providing both a further weapon for investigation of discharges (in so far as these originate in electrode surfaces) and an example of high-voltage equipment of interest to the biological faculties. Either a further D.C. generator or a radio-frequency accelerator will be installed next year, depending upon development of the present research groups.

The range of engineering activity has now extended over so wide a field that many feel that the undergraduate courses at universities may be in need of quite drastic modification. There is a wide divergence of opinion as to what form such modification should take; but perhaps a majority of critics believe that more emphasis on fundamental principles is needed, with less time spent on design study. The Nuclear Particle Laboratory at Queen Mary College, with an over-riding emphasis on the fundamental theory of matter, is a step in this direction.

# MECHANISM OF PROTOPLASMIC MOVEMENT

By Prof. WILLIAM SEIFRIZ
University of Pennsylvania

THE streaming of protoplasm and the apparently autonomous movement of particles within it have long been problems in biology, and many have been the theories to explain them. Protoplasmic flow has been attributed to every imaginable force, from surface tension to electro-osmosis, without much evidence to support any of the hypotheses.

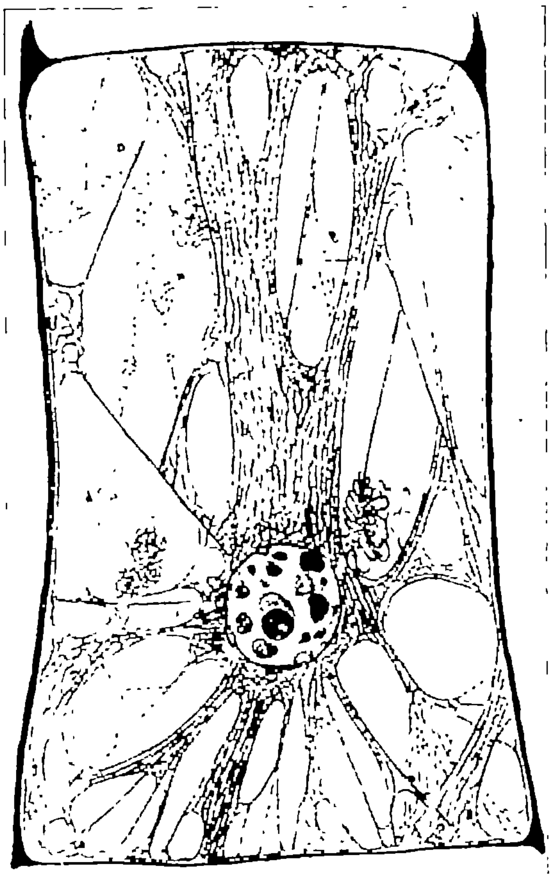
Early in college training, Prof. E. A. Andrews directed my attention to the movement of protoplasmic particles. He referred particularly to a form of activity which was neither cyclosis nor the "vulgar pedesis dance discovered by Brown in dead regions of plants. *These* particles", said Prof. Andrews, "are travelers, going places". In ciliated Protozoa of the closely related families Vorticellidæ and Stentoridæ there are particles less than 1 mμ in diameter which move ten to one hundred times their own length in a second or two. They may pass close to one another, proceeding in opposite directions[1].

In subsequent years my attention was centred on the flow of protoplasm. Recently, I again turned to the particles, hoping to find in their motion a clue to the mechanism of protoplasmic streaming. Isolated cells from cultures of plant 'cancers' served as material—kindly supplied by Dr. R. J. Gautheret.

Some years ago I[2] advanced a theory of protoplasmic flow based on the rhythmic pulsations of a slime mould. The peristaltic waves, when accelerated by time-lapse photography, are readily seen. They much resemble the trains of waves in a stimulated muscle fibre. There is no question of the presence of rhythmic pulsations; but, though synchronized with the fifty-second period in reversal of flow, they are not the cause of cyclosis. One of the weaknesses of the theory was its failure to explain the simultaneous flow of protoplasm in opposite directions in parallel currents. One occasionally sees in Protozoa, but better still in a sheet of protoplasm in some species of slime moulds, as many as nine channels of flow in which adjoining currents flow in opposite directions, 'rubbing shoulders' as it were, without mixing, and without an evident wall between the two (top centre in the accompanying figure).

All the foregoing difficulties were apparently solved by a 'new' theory of cyclosis which appeared several years ago in four articles from the pens of six authors[3-6]. Frey-Wyssling[3] deserves credit for the theory, though Meyer and Mark[6,7] claimed a twenty-year priority, in so far as the theory applies to muscular contraction. The suggestion made by all six authors is that within the protoplasmic stream polypeptide chains fold and unfold, the protein molecules moving forward like an army of caterpillars, carrying the surrounding medium with them.

The curling and uncurling of molecular fibres is an attractive mechanism by which to account for the flow of protoplasm. It is, however, a pure assumption, permissible only if certain conditions are met. Curling may be accounted for; thermic agitation will do it. Stretching, however, is another matter. At every point where folding occurs sufficient energy must be transmitted to stretch, or untwist, the folded chain in opposition to thermic agitation. The



A typical plant cell (after Heidenhain)

proponents of the theory present no evidence to show that this energy is available, and that there is also present the complex mechanism necessary to use the energy and accomplish the untwisting. In addition to this negative evidence, I offer the following observations on the movement of protoplasmic particles in disproof of the caterpillar hypothesis.

The first hint which ultimately led to a clarification of the problem came early in my work when I observed three independent rhythmic pulsations in a plasmodium. Kamiya[9] later increased this number, and referred to the plasmodium as a polyrhythmic system. This means that there are many excitation foci within one protoplast.

Plant cells often form delicate protoplasmic threads along which move particles of numerous kinds. The particles are frequently of greater size than the diameter of the thread which carries them. It is not possible, therefore, that the particles are moved by the feeble stream of endoplasm in the lumen of the protoplasmic thread, for they are embedded in the outer cortical layer. The situation is comparable to a 5-mm. sphere moving within a 5-mm. tube which has a 1-mm. bore and a 2-mm. wall.

Final proof that a synchronized migration of curling and uncurling protein chains within the stream is not the mechanism of protoplasmic flow is to be had in the occasional erratic activity of the particles. The movement of the particles, when they are of fat, cannot possibly be autonomous, and this holds for mitochondria as well. The Belgian school of cytologists is convinced that mitochondria are capable of self-repulsion. The French school, on the contrary, is opposed to such an assumption.

Protoplasmic granules along a strand usually move smoothly and continuously as if carried by the stream, each particle maintaining its position in line. Frequently, however, striking disturbances occur. Several particles will suddenly increase their speed and hurry away from the others. Sometimes one or two particles will reverse their course and proceed in the opposite direction; a collision more than likely resulting. Two or more momentarily quiet particles may suddenly assume activity and move rapidly away from each other. Occasionally, two particles will approach each other, collide, and then proceed in the opposite directions. None of these erratic movements can be accounted for by a protoplasmic stream, and, as I have said, it is quite impossible that fat droplets should have autonomous motility.

Certain of the behaviourisms described above are duplicated by the waves which traverse muscle fibres. Particularly striking is the approach and collision of two waves, precisely as in a protoplasmic thread, except that particle is substituted for wave. One is forced to the conclusion that the mechanisms are identical.

That the foregoing phenomena are not restricted to protoplasmic threads and muscle fibres becomes increasingly evident as one surveys the whole field of cellular activities. I shall refer only to those shown me by my colleagues at the Sorbonne and the Pasteur Institute. Dr. J. Comandon and Dr. P. de Fonbrune[10] demonstrated, in hyphæ of fungi, the three types of motion which I have described, namely, the passive transport of particles by the protoplasmic stream, Brownian movement, and an erratic activity here brought on by artificial irritation. The last of these is the type of motion which I believe to be due to nerve-like impulses emanating from excitation foci in the living cell.

A similar situation exists during mitosis of the *Triton* red blood cell[10]. Here, just prior to cell division, the nucleus commences to rotate, and continues doing so for some minutes. There is no cyclosis to account for it. The nucleus is apparently responding to a stimulus originating in the cytoplasm, that is, it is moved by excitation forces.

Very striking was the sudden assumption of activity by the centrosome, or centrosome area *en masse*, in polymorphonuclear cells from mammalian blood. During mitosis the centrosome oscillates half the length of the cell, with a rhythmic period of thirty seconds. Because of the motion, the surrounding cytoplasm is stretched, indicating high elasticity. There is no cyclosis. I had the pleasure of observing this behaviour of the centrosome in blood cells in the laboratory of Dr. A. Policard and Dr. M. Bessis[11].

With the exception of the passive movement of particles when carried by flowing protoplasm, all the foregoing activities in living cells are the result of stimuli arising at excitation foci.

Somewhat similar is the activity of chondriosomes described by Buvat[12].

Before attempting an analysis of the force responsible for protoplasmic movement, I should like to emphasize its universality by directing attention to the resemblance of the rhythmic phenomena which occur in nerve, muscle and the relatively undifferentiated protoplasm of the slime mould. The Myxomycetes, or Mycetozoa, are a very lowly form of life, yet they pulsate rhythmically and show peristaltic waves just as does the musculature of man. The pulsations in both cases are accompanied by a rhythmic rise and fall in electric potential. Kamiya[14] has measured this potential in the Myxomycete *Physarum*. Any statement on the nature of the force involved in protoplasmic movement must include the similar activities in muscle and nerve.

In explanation of protoplasmic movement one cannot turn to electrical currents such as are conducted along metal wires. Adrian[13] swept away all such analogies in reference to the nervous impulse as long ago as 1912. We must, therefore, seek a force which meets, so far as possible, all biological conditions and has the full recognition of the physical chemist. There are a number of attractive possibilities. Phase phenomena and the forces responsible for the stability of coacervates are active in living systems. In these fields Joly and Dervichian[15] have done much which has a direct and significant biological bearing. Dobry[16] directs attention to some extraordinary analogies between the behaviour of coacervates and protoplasm. Weissenberg[17] has described the flow of coacervates against gravity, which is a protoplasmic quality.

But it is to 'fields' that I wish to turn for an interpretation of the impulses which activate protoplasmic movements. Let me first say that, in rejecting the part which fibres are said to play in the streaming of protoplasm, I do not thereby ignore the obvious part which fibres play in living material where they are needed and can be used. In the cellulose framework of plants, in muscle, tendon and in nerves where the linear form serves well, Nature uses fibres. But a fibre is of no use for doing mechanical work if there is no place to attach it. Our present problem is not one of tensile strength but of propulsion.

Debye[18] has well interpreted fields such as surround polar molecules and colloidal particles. Molecules similar to $H_2O$, $NH_3$ and HCl are surrounded by static electric fields which convert them into dynamic systems, into electrically charged elementary particles. A second molecule coming within close range of such a dipole will acquire a field, or electric moment. Being thus polarized, it will interact with the first molecule. The work of Debye and others, notably London, has led to the now widely accepted fact that polar molecules are enveloped by electric forces which may be derived from pure coulombic interactions between charges. These are essentially short-range forces which do not extend beyond three or four molecular diameters. Long-range forces will accomplish more.

The total force with which a particle, consisting of many molecules, will act on a second particle may be ascertained by integrating over the first sphere and arriving at the reaction between this sphere and a molecule in the second sphere. In a similar manner may one integrate the molecules in the second sphere and thus arrive at the final total reaction. Such a procedure leads to the prediction that in appropriate circumstances short-range molecular forces may build up to appreciably strong long-range forces. Overbeek[19] has recently made direct measurements of the molecular attraction between parallel glass plates at distances of the order of the wave-length of visible light (5000 A.).

If we turn to the still larger particles of lyophobic colloidal suspensions, then we have additional forces, namely, the familiar electric charge on the surface, due to preferential adsorption or to dissociation at the surface of the particle. The range of the coulombic interaction of these colloidal charges is determined by the depth of the ionic cloud surrounding the particle.

If, now, we determine the total interaction energy between two colloidal particles, we find that under suitable conditions it shows a pronounced maximum at an appreciable distance. It is for this reason that some colloidal suspensions are so stable and their coagulation time so great.

With the foregoing background we can apply Szent-Györgyi's[20,21] hypothesis of muscular contraction. The double layer of ions which surrounds a muscle fibre will set up an electric field. If a wave of depolarization travels along the surface, this will have the same effect as if we had pulled electrodes along the axis. The precise mechanism is not known; but it is only necessary to assume that a local depolarization is generated which runs parallel to the fibre axis. If, instead of a muscle fibre, we have a thread of protoplasm within a cell, then a wave of depolarization giving rise to a field parallel to the axis would carry particles and fluids with it.

Whether we are dealing with a single isolated fibre (lower left in figure), or with 'fibres' separated by cortical layers of oriented molecules lying parallel to each other so as to form a sheet of protoplasm (upper centre in figure), is the same in the end. Impulses travel back and forth, rhythmically or spasmodically, moving the cytoplasmic fluid and the particles in it.

Whatever our assumptions and hypotheses may be, a few facts remain clear: that the folding and unfolding of protein fibres is an assumption without the support of an adequate energy; that there is no evidence that fibres can function mechanically in a free droplet of protoplasm; that the mechanism of protoplasmic streaming is situated in the cortical layer, not in the endoplasm; and that rhythmic impulses traverse fibres of muscle, nerve and elementary protoplasm alike, measurable as differences in potential and visible in muscle and protoplasmic threads as trains of waves; and that it is these impulses which carry nerve transmissions and move protoplasm.

I wish to express my thanks to Dr. R. J. Gautheret and Dean Albert Chatelet, of the Sorbonne, for the hospitality which made this research possible.

# OBITUARIES

## H. A. P. Jensen

I FIRST met Hereward Jensen at the British Association meeting in Newcastle in 1949. We fell into conversation, and among other subjects we discussed the Nature Conservancy. Since he was clearly so interested in its work, I suggested to him that he might offer his services to the Conservancy as physiographer and naturalist. It was not for some considerable time after this talk that I realized that the then director-general of the Conservancy, Captain Diver, had a few weeks before asked me if I knew Jensen. Although he was only on the Conservancy staff for three years, he had made a name in that time and set a high standard of research and administration which will not easily be forgotten. His death at the age of thirty-two, the result of an accident in the train on his way home from a meeting of the Royal Geographical Society on May 11, was a tragedy. He leaves a widow and two small children.

Jensen was at school at Oldershaw (Wallasey), and took a degree under Prof. P. M. Roxby in the Department of Geography at Liverpool. On account of disability, he was not called up for active service in the War, but for nearly three years was a (temporary) civilian officer with the Intelligence Division of the Naval Staff at the Polar Research Institute, Cambridge, where he contributed to a number of the Admiralty geographical handbooks. In 1944 he was appointed to an assistant lectureship in geography at Manchester, and for the four years previous to his joining the Nature Conservancy he was a research officer at the Joint Intelligence Bureau, Ministry of Defence.

He was particularly interested in coastal studies, and had made intensive investigations in the Dee estuary. As a member of the Conservancy he extended his view, and had a remarkably good knowledge of much of the coast of Great Britain. Because of our common interest in the coast and our connexion with the Conservancy, we visited many parts of the coast together, and I soon realized how sound was his judgment and how reliable his mapping and investigations. Last year we worked together on Winterton Ness, and this year we visited part of the flooded areas together, and had made plans for a full investigation of the effects of the floods on the north Norfolk coast. He had also travelled in the Netherlands and Sweden, and had prepared the manuscript of a book on Sweden. Last year he was one of the delegates from the Nature Conservancy at the International Geographical Congress at Washington, and in America he was able to visit the south-eastern States and also make a tour of the eastern Nature reserves.

Hereward Jensen's death has been a grievous shock to his many friends, who will miss his cheerfulness and kindness of heart. Geographers and naturalists, whether they knew him personally or by reputation, will know that Nature conservation in its widest and best sense has lost a most able exponent. The members and staff of the Nature Conservancy mourn the loss of a valued friend and colleague.

J. A. STEERS

---

WE regret to announce the following deaths:

Prof. Alexandre Bigot, formerly professor of geology in the University of Caen and *correspondant* for the Mineralogical Section of the Paris Academy of Sciences, on April 20, aged eighty-nine.

Prof. D. Hanson, professor of metallurgy and director of the Department of Metallurgy, University of Birmingham, on June 12.

Mrs. Cora Brooking Hodson, formerly secretary of the Eugenics Society, and later honorary secretary of the International Federation of Eugenics Organizations, on May 21.

Prof. H. Rein, a director of the Max-Planck Institute for Medical Research, Heidelberg, aged fifty-five.

Dr. C. E. Walker, formerly lecturer in histology in the University of Liverpool, on June 6, aged eighty-two.

# NEWS and VIEWS

### Physics in the University of the Witwatersrand : Prof. F. R. N. Nabarro, M.B.E.

DR. F. R. N. NABARRO, who has been appointed to the chair of physics in the University of the Witwatersrand, was educated at Nottingham High School and New College, Oxford. He took a first-class honours degree in physics in 1937, and a year later obtained the same degree with first-class honours in mathematics, with distinction. During 1938–39 he was senior scholar of New College. In 1939 he became research assistant to Prof. N. F. Mott at the University of Bristol, and later joined the Army Operational Research Group of the Ministry of Supply. During 1945–49 he was Royal Society Warren Research Fellow, working in the University of Bristol, and in 1949 he was appointed lecturer in metallurgy in the University of Birmingham, which post he now holds. He was awarded the M.B.E. in 1946, a Beilby Memorial Award in 1950, and the D.Sc. degree of the University of Birmingham in 1952. During the War, Dr. Nabarro worked first on the theory of radar aerials and then on the accuracy of radar and the effectiveness of anti-aircraft fire and searchlights. His studies of anti-aircraft shell fragmentation led to similar work on ground targets, and he organized the calculation of the theoretical effectiveness of shell-fire and bombing, and compared this with the observed correlations between fire support and British casualties in Army operations. Apart from his work during the War, he has concerned himself largely with problems in the physics of metals. He has been particularly interested in the dislocation theory of slip in metals, and has contributed a number of important papers to this subject in recent years. He is now engaged on a book summarizing the mathematical problems arising in this theory. He is the author of some twenty-five papers of high scientific quality, and he has made notable contributions to the modern theory of metals.

### American Geophysical Union : Award of the William Bowie Medal

DR. BENO GUTENBERG, director of the Seismological Laboratory, California Institute of Technology, Pasadena, California, has been awarded the William Bowie Medal by the American Geophysical Union (Committee on Geophysics of the National Research Council). Dr. Gutenberg, who was born in Darmstadt, Germany, is known for his many contributions in the broad field of geophysics and related fields. He studied at the Technische Hochschule of Darmstadt and the University of Göttingen, where he obtained the degree of doctor of philosophy in 1911. He went to the United States in 1930, and became an American citizen in 1936. He has been professor of geophysics at the California Institute of Technology since 1930, and director of the Seismological Laboratory since 1947. He is author or co-author of many outstanding work in geophysics, including "Grundlagen der Erdbebenkunde", "Seismicity of the Earth", and extensive contributions in "Internal Constitution of the Earth", of which he was also the editor. He is president of the International Association of Seismology and the Physics of the Earth's Interior, of the International Union of Geodesy and Geophysics.

## The Greenwich Meridian

WHEN the Octagon Room of the Royal Greenwich Observatory was taken over by the National Maritime Museum, it was felt that the old meridian marked on the pavement was too inconspicuous; the Ministry of Works has accordingly installed a new line consisting of a brass strip let into a band of white stonework laid across the pathway outside the Observatory. The Greenwich Meridian was adopted as the Prime Meridian by the world in 1884 at the suggestion of the United States Government, which had called an international conference to consider the matter. It was defined as the north–south line running through the Airy transit circle in the Observatory. In the past, many prime meridians have been used. Eratosthenes naturally used the meridian of Alexandria, of whose great library he had been appointed librarian in 240 B.C.; Ptolemy, to avoid the difficulty of having both east and west longitude, used that of the Fortunate (Canary) Islands, the most westerly land known, so that all longitude should be measured eastwards. At one time there was an attempt to mate the prime meridian with the line of no magnetic variation; but the impossibility of unifying two lines which were inclined to each other at an angle and the impracticability of tying down hypothetical meridians running through the Canary Islands or the Azores had by the nineteenth century led many countries to adopt the meridians of their principal observatories. At one time England commonly used the meridian of St. Paul's.

## Expedition to Mt. Wrangell, Alaska

A JOINT expedition is being made this summer by members of New York University and the University of Alaska with the purpose of establishing a scientific observing station, principally for cosmic rays, on Mt. Wrangell in Alaska. The expedition will be led by Prof. Serge A. Korff, professor of physics in the College of Engineering, New York University, who will be the scientific director and principal scientist, and by Dr. Terris Moore, president of the University of Alaska, who will act as administrative director and be responsible for establishing the station. Although Mt. Wrangell (14,006 ft.) is not the highest mountain in Alaska, being topped by a number of peaks, of which the highest is Mt. McKinley (20,269 ft.), it has been chosen because its unusually flat top makes it an excellent landing-place for aeroplanes fitted with skis. Incidentally, it is the only 'live' volcano in Alaska, and it may be possible to utilize the steam that issues at the north-west end of its summit. A preliminary party is at present climbing the mountain, and experimental landings will be made by Dr. Moore in his special Piper Super-Cub aeroplane at convenient spots as they are discovered by the climbing party. By this means it is hoped to build up a series of landing places at various heights, and eventually to establish a safe landing field on the summit by which the station can be supplied with huts and other stores and permanent equipment. The proposed station, which will be the most northernmost cosmic-ray station in the world, will be operated on an inter-university basis, whereby interested organizations, by contributing *pro rata* to its maintenance, may send observing personnel and equipment there.

## Royal Society's Depository of Unpublished Mathematical Tables

SINCE the publication of the first list (see *Nature*, 169, 526; 1952) the following tables have been accepted into the Royal Society's depository of unpublished mathematical tables: Table de factorisation des nombres $N^4 + 1$ dans l'intervalle $3000 < N < 6000$ (A. Gloden); solution of the equation $(y'')^2 = yy'$ and two other equations (Admiralty Research Laboratory); dictionary of Laplace transforms (J. Cossar and A. Erdélyi); tables of Fresnel's integrals (D. H. Shinn); tables of the error integral of a complex variable (J. K. Skwirzynski); table des solutions de la congruence $x^4 + 1 \equiv 0 \pmod{p}$, $600000 < p < 800000$ (A. Gloden); tables of the complex Jacobian zeta function (National Physical Laboratory); tables of binomial coefficients (National Physical Laboratory); tables of Multhopp's influence functions (National Physical Laboratory); integrals of Bessel functions ($J_0$ and $Y_0$) (National Physical Laboratory); table of $\int_0^{2\pi} J_1^2\left(2k\sin\frac{\theta}{2}\right)\cos^2\frac{\theta}{2}\,d\theta$ (National Physical Laboratory); tables of two functions occurring in the theory of the reflexion of electromagnetic waves from infinite cylinders (National Physical Laboratory); table of an integral used in calculating profiles of water waves (National Physical Laboratory); tables of the Langevin function and its inverse (A. Young and T. Murphy). Further information about these tables can be obtained on application to the Assistant Secretary, Royal Society, Burlington House, London, W.1.

## Political Activities of Civil Servants

FOLLOWING the announcement on November 1, 1949, that the Government would give immediate effect to those recommendations of the Masterman Committee in its report on the political activities of Civil servants which would free some 450,000 Civil servants from existing regulations, the Government indicated that, before taking final decisions on the general principles of the report, joint discussions through the machinery of the National Whitley Council were desirable. The report of the joint committee afterwards appointed has now been published as an appendix to a White Paper in which the Government's proposals are detailed ("Political Activities of Civil Servants" (Cmd. 8783). Pp. 16; London: H.M.S.O., 1953; 6*d*. net). The statement points out that the extent to which Civil servants should be free to take part in political activities must be considered in the light of two conflicting principles. The desirability, in a democratic society, of all citizens having a voice in the affairs of the State and of as many as possible of them playing an active part in public life has to be set against the imperative demand of the public interest for the maintenance of political impartiality in the Civil Service and for confidence in that impartiality. In other words, it is an essential part of the structure of government in Britain that the Civil Service should not only be impartial but also be seen to be impartial.

The Whitley Committee suggested that between the two classes proposed by the Masterman Committee an intermediate class should be created, and the Government has agreed that this could be done without detriment to the interests of the State or the reputation of the Civil Service for political impartiality. The problem is where to draw the line, and the members of the Whitley Committee are themselves unable to reach agreement. The Government proposes to draw the line so as to include the five groups which both sides of the Committee proposed to include, but excluding junior executive officers and analogous grades, and to bar canvassing to Civil servants restricted in their political activities while allowing it by permission only to those in the intermediate group. The decision, which will give substantial political freedom to a further two hundred thousand Civil servants, appears to be reasonably circumspect, while experience demonstrates that the increased freedom will be used with good sense and discretion. Some 62 per cent of the Civil Service is now completely free of restrictions, and only 16 per cent is barred from participation in national political activities; and to many of those who seek it, permission to participate in local government may be given.

## Standard Solutions of Phosphorus-32

It has been found by the Isotope Division, Atomic Energy Research Establishment, Harwell, that phosphorus-metabolizing moulds grow readily in solutions containing phosphorus-32 used as radioactive standards and may cause losses of specific activity in the solution of up to 50 per cent in one week. To inhibit their growth, an addition of 1 per cent formaldehyde is therefore made to such solutions before dispensing and measurement. All solutions thus treated are clearly marked and carry a poison label.

## Congress of the Universities of the British Commonwealth

The Seventh Quinquennial Congress of Universities of the Commonwealth will be held in Cambridge during July 13–17 under the presidency of Marshal of the Royal Air Force Lord Tedder, chancellor of the University of Cambridge. Practically every university and university college in the British Commonwealth will be represented by a delegation of teaching and executive officers led by its vice-chancellor or principal, making a total of more than four hundred persons, and in addition there will be observers from many learned bodies and a party of ten university presidents nominated by the Association of American Universities. The present Congress is the seventh of the series organized (except for interruptions caused by the two wars) at five-yearly intervals since 1912 by the Association of Universities of the British Commonwealth (formerly the Universities Bureau of the British Empire), the previous meeting having taken place at Oxford in 1948. The chairman of the organizing committee is Sir Philip Morris, vice-chancellor of the University of Bristol and chairman of the Association. The Congress provides an opportunity for the free exchange of views on matters of current importance to the universities of the British Commonwealth, and the following subjects will be discussed at the sessions: government and universities, administration and academic duties, academic mobility in the Commonwealth, higher-technological education, and admission and selection of students. A general symposium will also be held on the question: What subject or subjects to-day are best fitted to fulfil the role played previously in the university curriculum by the classics? By invitation of Sir James Duff, warden of the Durham Colleges in the University of Durham, there will be a meeting of vice-chancellors, presidents and principals of member universities of the Association of Universities of the British Commonwealth at St. Mary's College, Durham, during the week beginning July 6. This conference will be devoted to private discussion of inter-university relationships and problems of administrative and educational policy common to the various universities of the Commonwealth. Both the above meetings will be private; but further information can be obtained from the Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1.

## University of Birmingham

The following have been appointed lecturers in the University of Birmingham: Dr. G. W. Greenlees (physics), R. W. Murray (zoology), Dr. W. T. Pell-Walpole and S. G. Glover (metallurgy) and P. S. Gelling (ancient history and archæology). The title of reader in systematic bacteriology has been conferred on Dr. K. A. Bisset, lecturer in bacteriology in the University.

The University Department of Engineering Production has received a further gift of £57,400 (under seven-year covenant) from Joseph Lucas and Co., Ltd., the firm which originally endowed the Department, and it is intended that this sum be used for the establishment of a centre for continued studies in engineering production and management. The University has acquired a house at 16 Norfolk Road which is being altered and refurnished and which will shortly be opened as the University of Birmingham Institute for Engineering Production. The aim of the Institute, which will be directed by Prof. T. U. Matthew, Lucas professor of engineering production, is to develop a series of short residential courses in engineering production and management subjects for executives in responsible posts in manufacturing industries. The work of the Institute will be reviewed and liaison with industry maintained through an advisory board, on which a number of industrial leaders will sit with the vice-chancellor and members of the Faculty of Science. It is hoped that the Institute will be opened on July 16 with a fortnight's course on "The Application of Work Study".

## University of Leeds: Appointments

The following appointments have been made in the University of Leeds: Prof. T. L. Bywater, at present Strathcona Fordyce professor of agriculture in the University of Aberdeen, to be professor of agriculture and head of the Department of Agriculture; Prof. R. F. E. W. Peel, professor of geography in the University, to be head of the Department of Geography in succession to Prof. A. V. Williamson (see *Nature*, June 6, p. 1002). The title and status of reader have been conferred on the following members of the University: Dr. A. D.

Walsh (physical chemistry) and Dr. A. S. Leah (applied thermodynamics). E. W. F. Seymour has been appointed lecturer in the Department of Physics.

## Geological Society : Officers and Council

THE officers and council of the Geological Society have been elected for the ensuing year, as follows : *President*, Prof. W. B. R. King ; *Vice-Presidents*, Dr. O. M. B. Bulman, Dr. L. R. Cox, Prof. L. Hawkes and Dr. G. M. Lees ; *Secretaries*, Prof. S. E. Hollingworth and Mr. A. J. Butler ; *Foreign Secretary*, Prof. O. T. Jones ; *Treasurer*, Mr. P. Evans ; *Council*, Dr. S. Buchan, Dr. O. M. B. Bulman, Mr. A. J. Butler, Dr. G. F. Claringbull, Dr. L. R. Cox, Mr. H. G. Dines, Mr. P. Evans, Dr. W. F. Fleet, Prof. L. Hawkes, Prof. S. E. Hollingworth, Dr. R. G. S. Hudson, Prof. O. T. Jones, Prof. W. Q. Kennedy, Prof. W. B. R. King, Dr. J. F. Kirkaldy, Dr. G. M. Lees, Dr. W. A. Macfadyen, Prof. L. R. Moore, Miss H. M. Muir-Wood, Dr. J. S. Sandford, Prof. J. H. Taylor, Dr. H. D. Thomas and Dr. A. K. Wells.

## The Night Sky in July

NEW moon occurs on July 11d. 02h. 28m., U.T., and full moon on July 26d. 12h. 20m. The following conjunctions with the moon take place : July 7d. 13h., Venus 8° S. ; July 8d. 11h., Jupiter 5° S. ; July 12d. 15h., Mercury 3° S. ; July 19d. 01h., Saturn 8° N. At the beginning of the month Mercury sets at 21h. 30m. ; but it approaches the sun too closely to be seen for the greater part of the month and is in inferior conjunction on July 25. Venus is a morning star, rising at 1h. 30m. on July 1 and about 1h. 10m. at the middle and end of the month ; the visible portion of the illuminated disk varies from 0·54 to 0·67, and its stellar magnitude averages – 3·7 during the month. Mars is too close to the sun to be favourably observed. Jupiter is a morning star, rising at 2h. 05m., 1h. 20m. and 0h. 30m. on July 1, 15 and 31, respectively, and is moving eastward in the constellation Taurus. Saturn sets at 0h. 15m., 23h. 20m. and 22h. 20m. at the beginning, middle and end of the month, respectively, and is moving eastward in the constellation Virgo, stellar magnitude about 1. On July 11 there will be a partial eclipse of the sun, of greatest magnitude 0·201, but it is invisible at Greenwich. On July 26 there will be a total eclipse of the moon, also invisible at Greenwich ; the beginning will be visible generally in North America, South America, Antarctica, the Pacific Ocean, Australasia and the extreme north-eastern parts of Asia, and the end generally visible in the Pacific Ocean, the north-western tip of North America, Australia, Antarctica, the Indian Ocean, and eastern and central Asia. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich : July 3d. 0h. 10·8m., 22 Pisc. (*R*), and July 30d. 3h. 12·1m., λ Pisc. (*R*) ; *R* refers to reappearance.

## Announcements

H.R.H. THE DUKE OF EDINBURGH has been pleased to accept honorary fellowship of the Institute of Welding.

THE Minister of Fuel and Power has appointed Sir George Thomson to be chairman of his Scientific Advisory Council in succession to Sir Alfred Egerton, who retires at the end of June when his term of office expires. He has also appointed Mr. Kenneth Gordon, director-general of ordnance factories, Ministry of Supply, to be a member of the Council.

DR. B. P. UVAROV, director of the Anti-Locust Research Centre, London, has been elected an honorary member of the Nederlandsche Entomologische Vereeniging, in recognition of his services to entomological science and for his contributions to the study of the Orthoptera in particular.

THE following have been appointed to lectureships in the University College of North Staffordshire : Dr. D. E. Davies (physics) and Dr. A. H. Wallace (mathematics).

THE annual Machinery and Implement Exhibition of the Sports Turf Research Institute (Bingley, Yorks) will be held on the sports grounds of Lever Bros., Port Sunlight, Wirrall, Cheshire, during July 1–2. A wide range of modern turf machinery, implements and ancillary equipment will be shown, as well as a display illustrating the scientific and educational work of the Institute. The Exhibition is only open to affiliated clubs and subscribers to the Institute.

THE thirtieth meeting of the Australian and New Zealand Association for the Advancement of Science is to be held in Canberra, during January 13–20, 1954. Further information can be obtained from the Association, Science House, 157 Gloucester Street, Sydney, New South Wales, or from Dr. C. Barnard, honorary local secretary of the Association, Box 109, City, Canberra, A.C.T., Australia.

THE Society for Experimental Biology is holding a symposium on "Active Transport" at Bangor, Caernarvonshire, during July 13–17. The speakers will include : Th. Rosenberg, H. Davson, J. A. Ramsay, J. R. Robinson, J. A. Kitching, D. C. Spanner, J. W. L. Beament, E. F. Gale, W. Wilbrandt, P. G. LeFevre, A. Rothstein, A. C. Frazer, F. W. R. Brambell, W. A. Hemmings, M. Maizels, E. J. Harris, J. F. Sutcliffe, H. Lundegårdh, R. Scott Russell, F. C. Steward, H. H. Ussing, R. D. Keynes, A. L. Hodgkin, E. J. Conway, R. E. Davies, H. B. Steinbach, J. F. Danielli. Those wishing to attend should write to Dr. D. J. Crisp, Marine Biological Station, University College of North Wales, Bangor, Caerns.

THE following conferences in physics have been arranged in England in the week following the meeting in London during July 8–9, 1954, of the General Assembly of the International Union of Physics : a conference on experimental and theoretical nuclear physics during July 13–17, 1954, in the University of Glasgow ; a conference on the physics of the solid state, with special reference to defects in solids, during July 13–17, 1954, in the University of Bristol. Both conferences are arranged in co-operation with the International Union of Physics. Further information will be published in due course.

THE Textile Institute is offering a bursary, of value £450, tenable at the Massachusetts Institute of Technology, for nine months from September next until May 1954. The bursary, offered under the terms of the Frank Wright Memorial Fund, is open to associates of the Institute of British nationality, and is intended to enable the successful candidate to undertake a broad programme of study and research into problems concerning cotton spinning, doubling and twisting. Particulars can be obtained from the General Secretary, Textile Institute, 10 Blackfriars Street, Manchester 3 ; completed applications must be received by July 9.

# PHOTOGRAPHIC SCIENCE AND TECHNIQUE

A CONFERENCE on photographic science and technique was held by the Scientific and Technical Group of the Royal Photographic Society on May 16 in the Arthur Worthington Hall of the University of Manchester. Dr. G. N. Burkhardt (Department of Chemistry, University of Manchester) opened the proceedings, and the chairmen of the morning and afternoon sessions were Mr. V. Gallafent (Scientific and Technical Group of the Royal Photographic Society) and Mr. C. W. Bradley (British Cotton Industry Research Association). The success of the conference was attributable in a large measure to the contributions from the Manchester area, and the self-restraint of speakers in keeping to their allotted times.

The first paper was not directly related to photography, but dealt with the legibility of print when projected from 3¼-in. square lantern slides. This clearly is a matter of importance to audiences, particularly at scientific meetings, for as Dr. R. Ollerenshaw (Manchester Royal Infirmary) pointed out there is evidence that the average eyesight of undergraduates is inferior to that of the eighteen-year-old National Service entrants and deteriorates during university residence. Whatever the form of the lettering, the illumination of the screen should be high, the contrast between the lettering and background strong, and preferably with the letters white on black. The greatest distance at which members of the audience should be seated should be six times the width of the screen (owing to the limited acuity of the eye) and the nearest distance twice the width of the screen (otherwise a tiresome rotation of the head itself must supplement the normal movement of the eyes). The seats should be grouped within a triangle of 60° angle with its apex at the centre of the screen.

A study of type faces shows that upper-case Gill Sans Bold is best for acuity, readability and speed of reading. The italic form is useful for ordinate legends to graphs. The individual characters should be not less than 2 mm. high on the slide, and lower-case type should be used only when this condition can be met. It has been found best to do all lettering with a small printing-press, a process which is at least as quick as good stencilling. The gap between lines of type should be equal to the body height of the type, and, as far as possible, each line should carry one item of the message. Diagrams and lettering in journals and books cannot well be used for lantern slides, or vice versa.

P. C. Smethurst (Smethurst High-Light, Ltd., Bolton) discussed the use of supplementary lenses with a telecentric stop. If a positive supplementary lens is arranged so that its rear principal focus is at the front nodal point of the camera lens, all the principal rays in the object space are parallel to the axis. The photograph then displays perspective such as would be obtained if the objects photographed were at infinity, and all measures of size on it are relatively correct, whatever the distances of the objects. The same device thus avoids the necessity for exact location of objects along the axis when it is important to measure sizes. Variations in perspective are obtained by placing the supplementary lens at other positions along the axis, so that the pencil of principal rays in the object space is divergent or convergent. A double system, sometimes useful, is obtained when a supplementary lens (a telescope objective) is used in the same way on each side of a camera objective.

The illumination of deep and narrow cavities by means of a concave mirror reflecting light from a lamp set to one side was then described by F. Wardlaw (Christie Hospital, Manchester). Photographs are taken through a central aperture in the mirror, the subject being observed by means of a two-mirror periscope of which the first mirror is a thin sheet of unsilvered glass. The aberrations of a concave mirror used at an angle help to smooth out the image of the lamp filament, and for the same reason high optical quality is not necessary, but care should be taken to keep light off the front edges of the cavity by suitable focusing.

Dr. H. J. J. Braddick (Department of Physics, University of Manchester) pointed out that the photography of tracks in cloud chambers involves contradictory requirements. For example, the minimum delay between the arrival of a particle and the expansion is 10 msec. Then a period up to 250 msec. is required for the water drops to grow. The shorter this period can be, the more nearly will the water drops represent the particle track; but the longer they are allowed to grow, the brighter will the track be. It is, of course, difficult to get adequate illumination because the camera lens must be stopped down to get a fair depth of the chamber sharp in the photograph. In order to get adequate illumination, high-power flash tubes or heavily over-run tungsten lamps are used. Practical trial indicates that prolonged development increases the effective speed of the photographic material—a result which, from the discussion following the paper, was not unexpected by the photographic experts. If the inevitable delay between the arrival of a particle and the expansion is increased, and an electric field is established across the chamber, the positive and negative ions separate, forming two parallel tracks from the intensities of which the relative concentrations of ions of the two signs may be estimated. This technique is not possible with nuclear track plates.

In discussing the distortion of tracks in plates for recording nuclear particles, J. V. Major (University of Manchester) said that measurements indicate that there are two components, one centrally symmetrical and the other like a shear across the plate. Uneven drying (from the edges inwards) can account for part of the distortion, but the origin of the remainder is not clear. Temperature gradients during development may be responsible.

E. W. H. Selwyn (Kodak, Ltd.) considered progress in the physics of the developed image. Our qualitative knowledge of the make-up of the characteristic curve, of granularity, graininess, resolving power and sharpness, is fairly good, though there are still outstanding problems, and little quantitative information is available. Fuller details are available in the *Journal of Photographic Science*, 1, 60 (1953).

Methods of high-speed photography, based on dissection of the image, were then described by Dr. J. S. Courtney-Pratt (University of Cambridge). If a plate embossed with a large number of lenses is placed near the focal plane of a camera, a series of images of the camera lens will be formed on the sensitive material, and these taken all together form a picture of what is in front of the camera, rather like a half-tone illustration. When a small aperture is moved across the camera lens, a continuous line of overlapping small images is formed behind each element of the lenticular screen, thus recording any movement in the objects in front of the camera. In practice, a series of apertures is used, like the original Baird scanning disk for television, and each lenticular element produces a 'raster'. The fundamental advantage of this system is that the speed of the scanning disk, being simple rotation, may be made very high, and with bright enough (for example, self-luminous) subjects records may be obtained at the rate of 4 million/sec. The same system reversed may be used for 'unscrambling' in slow motion or statically. A complete description, including variations on the above principle, is given in the *Journal of Photographic Science*, 1, 21 (1953).

C. Burns (British Iron and Steel Research Association) described how the problem of recording the very fast motion of lumps of material swirling round in the hollow just beyond the tuyères in blast-furnaces was dealt with. Stereoscopic motion pictures were made using two ports into a tuyère and a mirror system to produce the necessary pairs of pictures side by side on each frame of a 16-mm. film. When the pictures are projected, individual lumps of material can be recognized, against the very heterogeneous background. The location (along the axis of the tuyère) is measured by a quadruple projector arrangement of which the movements are linked. First, the two beams of a pair are made to coincide on some fixed detail in the tuyère, one on each of the projected pictures. The other two beams are then made to cross in space at the distance of the fixed detail in question, and the second pair of beams locked to the first pair. If the first pair of beams is now made to coincide with some other detail, the second pair follows its movements and intersects in space at the original distance of the new detail.

A. J. Insall (Shell Petroleum Co., Thornton le Moors) described the functions and some of the equipment of an industrial photographic section of a laboratory. One of the most important duties of such a section is to be able to repeat record photographs exactly; for this purpose arrangements must be made to locate any object precisely, to be able to duplicate the lighting arrangements and to be able to set the camera to given conditions. Records of all these settings must be kept, for it is commonly the case that photographs (for example, of pistons) require to be repeated, for comparison to be made to detect changes, sometimes at long intervals. Artistic quality (but not the technical quality) is usually unimportant, so that for recording deposits on elements of mechanisms, for example, use may be made of completely diffused lighting. Colour photography is very useful in such cases, since the additional information (on the colour) is valuable.

# LIBRARY CO-OPERATION IN GREAT BRITAIN

UNDER the title "Library Co-operation in Great Britain", the report of a critical survey of the working of the National Central Library, London, and the Regional Library Bureaux, made by Mr. R. F. Vollans, deputy city librarian of Westminster, for the joint working party of the executive committee of the National Central Library and the National Committee on Regional Library Co-operation has been published*. The working party's original terms of reference were to consider methods of dealing with areas of union cataloguing at the Regional Bureaux and at the National Central Library; means of improving the efficiency of the system and its comprehensiveness; the financial requirements for coping with the present system and sources from which money can be obtained; what would be reasonable current budgets for the bureaux if this re-organization were effected; and the relationship of the union catalogues of the bureaux and the national union catalogue of the National Central Library. In deciding that the survey should be undertaken by a single individual on its behalf, the working party extended these terms of reference and instructed Mr. Vollans to deal with the coverage by each system of the libraries within its own area, co-operation within each region, the national inter-lending system, union catalogues, the recruitment, qualifications and superannuation of bureau staff, the financing of the regions, and adult education.

In accordance with these instructions, which were further detailed, Mr. Vollans, following an admirable historical survey, reviews in successive chapters the working of the regional library systems, inter-library loan procedure, the scope of service and reasons for non-availability of books, the provision of books to adult classes, union catalogues, subject specialization, bibliographical information, staff and finance. His generous tribute to the efficiency and enthusiasm of the staffs concerned in inter-library loans and his conviction as to the importance of such work do not prevent Mr. Vollans from frank criticisms of the weaknesses or defects he has detected, whether of abuse of procedure, of inappropriate rules or woodenness or unimaginative interpretation of either rules or procedure. To the man of science the report is of interest mainly as an account of the background against which the evolution and organization of a national or regional lending library in science and technology must be considered; but the scientist who reads it may well be led also to a keener appreciation of the difficulties and waste of time which may be caused by inaccuracy or carelessness in making requests for books or periodicals.

The survey shows that all libraries appear to be playing their part in this national inter-lending service, and the small libraries appear to contribute just as much as the larger libraries; nor is it always the unduly large library system which provides the more expensive and more out-of-the-way books. Twenty-one university libraries and seventy-eight special libraries participate in the regional schemes, and these libraries lend more than they borrow, in that they have more specialized resources which would not find a place on the shelves of the ordinary public library. The present regions are based on geographical considerations, and are regarded as acceptable and workable units, with the exception of the regional library bureaux of Aberystwyth and Cardiff, which, it is recommended, should be merged to form a Regional Library Bureau of Wales. Except in the London area, the report recommends that all university and special libraries located within the area of a regional library bureau should become participant members of that bureau, and the bureau should be the agency, when necessary, for forwarding applications to the National Central Library. Within the London and Home Counties area, however, university libraries should make application direct to the National Central Library in respect of inter-library loans, and special libraries remain, as at present, outlier libraries of the National Central Library, membership of the London and South-Eastern Library systems remaining restricted to the public-library authorities of the area.

---

* Library Co-operation in Great Britain: Report of the National Central Library and the Regional Library Bureaux. By Robert F. Vollans. Pp. xii+189. (London: National Central Library, 1952.) 5s.

As regards the suggestion that the Science Library, London, might be in a position to screen scientific and technical applications before passing them to the National Central Library, Mr. Vollans recommends no deviation from the present practice. He points out that three distinct aspects of the Science Library service should be considered here: first, the Science Library is a reference library serving some twenty-two thousand readers; second, it operates a loans requisition service for books and periodicals to firms, institutions and libraries (through the medium of the National Central Library), satisfying in 1950 more than forty thousand of 72,295 requests*; and thirdly, it operates a photocopying department which last year satisfied 20,348 out of 29,660 requests. In addition, some 230 of the 1,300 corporate bodies, mostly business firms, on the loans list provide details of their own holdings for incorporation in a supplementary union catalogue at the Science Library, and through this supplementary scheme 4,799 requests were satisfied last year. At present, however, the Science Library is not in a position to supply all the books required, and, though its periodical holdings are extensive, Mr. Vollans suggests that it would be wiser in the interests of consistency if the National Central Library continued to act as the clearing-house for all national and international loans. Ultimately, however, he visualizes the National Central Library as ceasing to concern itself with British publications; and, though he gives no clear indication of his views as to the future of the Science Library or its place in the new regional system, it seems possible that the new scheme whereby the Treasury gives a grant for the purchase of extra copies of special types of books and periodicals, which could be held originally but which would be available for loan, in extension of the idea of regional reference libraries for commerce and technology, would apply to the Science Library also.

Besides current periodicals, fiction and some other categories, Mr. Vollans would exclude from inter-library lending books in print costing 25*s.* or less, so far as the National Central Library is concerned, and those costing 12*s.* 6*d.* or less from the scope of the regional bureaux. He also recommends that the National Central Library should cease to purchase books for use in the system of inter-library loans, and that it should transfer to the various local education authorities the provision of books to adult classes. Both these steps would liberate staff which could be used on other activities, particularly in bringing the present national catalogues up to date and in compiling the new foreign union catalogues which, he suggests, should be the main responsibility of the National Central Library in this field.

The survey proves that the Union Catalogue is a necessary adjunct in the nation-wide service of inter-library loans, and the duplication of entries is not as heavy as might have been expected. Mr. Vollans recommends that the existing regional and national union catalogues, as at present compiled, should only continue until an agreed specified date; after this, the regional union catalogues should contain entries for British books as they appear in the British National Bibliography notified by libraries to the Bureau, using the British National Bibliography numbers, and entries for all other books should be reported either directly on sheaves or by slips, only the latter entries being sent also to the National Central Library. The practice of producing the catalogues in sheaf form will no longer be necessary, and Mr. Vollans makes other proposals for achieving economies in procedure. Much stress is laid on the question of staff, which he regards as a decisive factor in increasing administrative efficiency and reducing the present excessive costs of the inter-library loan service. Apart from the question of qualifications and adequate salaries, he points out that seconding or the adoption of a superannuation scheme which allows interchange of staff between libraries of all kinds is essential for providing the security of tenure and overcoming the difficulty of pension rights which will otherwise hinder the recruitment of staff of the requisite experience.

As regards finance, he recommends an approach to the Treasury with the view of obtaining a grant, to be spread over three years, for the purpose of bringing the regional union catalogues up to date. If this grant is not forthcoming, it is suggested that the National Central Library should direct to the bureaux some of the money saved by discontinuing the purchase of books for its own stock and for adult classes, for the same purpose of bringing the catalogues up to date and thus enabling the National Central Library's own catalogue to be brought up to date.

In an introduction to Mr. Vollans's report, Mr. W. A. Mumford indicates that the report of the joint working party, of which he is chairman, will owe much to Mr. Vollans, although the working party is not in agreement with all the latter's findings.

# BRITISH ELECTRICAL AND ALLIED INDUSTRIES RESEARCH ASSOCIATION

## REPORT FOR 1952

THE thirty-second annual report of the British Electrical and Allied Industries Research Association (usually referred to as the Electrical Research Association) records the maintenance of the activities of the Association at a high level and their expansion in certain directions*.

At the outset, it is noted that the Association has operated this year under new terms of grant from the Department of Scientific and Industrial Research, and it was in relation to these new grant conditions and to the projected building of new laboratories at Leatherhead that the council of the Association last year launched an appeal for an increase in members' subscriptions and for capital contributions. The response to the appeal has been very gratifying, and as a result the Department grant has not only been maintained but slightly increased. Capital contributions amounting to nearly £200,000 have already been promised, subject to the institution of building operations, and part has already been paid.

---

* Thirty-second Annual Report of the E.R.A. for the Period ended 31st December 1952. Pp. 102. (Leatherhead: British Electrical and Allied Industries Research Association, 1953.)

The whole range of the research activities of the Association is summarized in nineteen separate sections in the report. It is, however, a little difficult to form from the report an adequate picture of the relative scale of effort devoted to the various branches of work. Much emphasis is evidently placed, as in previous years, on the work on dielectrics; part of this work being carried on at the Association's laboratories at Perivale, and part under the extra-mural programme at the National Physical Laboratory and in the Universities of Oxford, Durham, Bristol, Liverpool and London. This research ranges from fundamental theoretical work on the physics of insulating materials to directly applicable investigations concerned with the production of stabilized capacitors. On magnetic materials, fundamental work on the production and properties of electrical sheet-steel is in progress in the laboratories of the British Iron and Steel Research Association, this work being under the control of a joint committee of this Association and the Electrical Research Association. Measurements on magnetic sheet-steel and work on permanent magnet materials are being pursued largely as extra-mural researches.

Work on circuit breakers and circuit-breaking phenomena continues at a high level, and progress is reported in multiple break switches for high voltages. The report mentions, in passing, that "This year is the 25th anniversary of the gas-blast and the 21st anniversary of the baffle side-blast switchgear inventions of Dr. Whitney and Mr. Wedmore. The vital arc-control element in most modern high-power switchgear throughout the world, embodies in whole or some essential part their ideas and inventions". A model D.C. transmission link simulating high-voltage operation is now practically complete, and it is mentioned that "On the full-scale trial scheme a specific proposal has emerged relating to the cross-Channel power link and is being considered".

The network analyser, which has been under construction for some time, has been in operation on a limited basis, and additional sections of network elements are being incorporated as components are delivered. The analyser has already proved its value in a number of researches, particularly that of re-striking transients on the 132-kV. system of the British Electricity Authority. In the field of power generation, the most important problem is to raise the working temperatures of steam turbines. Extra-mural work at the Imperial College of Science and Technology, London, includes a programme for the measurement of the properties of steam up to 6,000 lb./sq. in. and 1,400° F. Work is also in progress at the National Physical Laboratory on steels suitable for components operating at 1,100° F.

During the past few years, the Electrical Research Association has been investigating the potentialities of wind-power in the British Isles. The experimental station in Orkney has been operated but is not yet in full commission, and arrangements are in hand with the College of Aeronautics for the testing of prototype equipment. Efforts are also being directed towards the development of the fuel cell, and a new research team for work on the gas cell has been established.

In the agricultural field, the Association has met with considerable success in the development of grain-drying equipment, and further work is in hand on soil warming in open ground and on soil sterilization by *in situ* electrodes. The experimental heat pump has been in use for some time, and a direct comparison has been made between the performance of the heat pump and that of a gas boiler installation.

Mention is made of the close liaison which the Electrical Research Association maintains with the professional institutions concerned with its spheres of work. A new departure has been made in the establishment of a programme of colloquia which are held at the Association's laboratories and to which guest speakers are invited from time to time. This year, the Association has issued ninety-four reports to members. Twenty reports have been published as papers in the technical press, together with a number of articles written by members of the staff and extra-mural research workers.

---

# SCIENCE IN GOVERNMENT SERVICES

IN a recent address to the American Chemical Society (see *Nature*, June 13, p. 1055) Dr. L. A. DuBridge, president of the California Institute of Technology, was somewhat critical of the United States Government's organization for research, and, apart from the Los Alamos Scientific Laboratory, which is operated for the Atomic Energy Commission by the University of California, expressed the opinion that the Government is not getting full value from its many existing military laboratories. Dr. O. H. Wansbrough-Jones's review of the situation in Great Britain in his William Jackson Pope Memorial Lecture, "The Scientist's Place in the Services", before the Royal Society of Arts on April 29, struck a much more confident note. He gave substantial reasons for believing that in Britain we have found means of ensuring that science, especially when devoted to defence topics, can really flourish in peace-time under government control. The position which scientists gained in the stress of war has been retained, and the scientist has now a favoured and honourable place in the Services, including the Ministry of Supply, in which he no longer has to fight for opportunities to collaborate closely with the Services in such of their problems as the scientific approach might further. He has become conscious rather of the responsibilities being imposed upon him and is wondering how far they can be discharged.

Dr. Wansbrough-Jones began by reviewing the way in which the attitude of the Services to scientific men has changed, so that in the Second World War they were no longer limited to giving the Services what they wanted rather than what the Services needed, which, as Sir Henry Tizard pointed out, is not necessarily the same thing. Apart from the influence of scientists like Tizard, Fowler and others, who had been brought intimately into the defence picture before the War, the preparation of the Technical Register and the urge to help the war effort from every scientific laboratory in the country, Dr. Wansbrough-Jones thought that there were three main factors responsible for scientific men achieving a position in which their powers are being fully exercised. The first is the dominant position in fields of defence science that the Government Establishments have achieved. The real knowledge of radar, service communication problems, explosives and propellants and chemical warfare is to be found in the Service Establishments, and at first even the most eminent outside scientists would be able to contribute relatively few ideas. The second factor is the increasing realization that a major scientific profession exists which might have its own contribution to make in its own terms. The third and most compelling factor of all is the practical and experimental proof, well exemplified in radar, that the scientist can contribute so much in non-technical and semi-technical fields. By the end of the War, all three Services had their own operational research teams at work in the field and at various headquarters, and in the Service Ministries and at many major commands there were senior scientists, of such rank and status that they could discuss, on equal terms with senior serving officers, the Services' problems from a scientific point of view. The general programme for research and development was evolved by such joint discussions, later to be carried out by the Ministry of Supply or of Aircraft Production, and by the Royal Naval Scientific Service. The arrangement really worked very well: the great step forward was the integration of the two disciplines, service and scientific, at a high level, so that the real problems were isolated, studied by the best scientific means available, and the results checked in the field by the method of operational research.

Generous tribute was paid by Dr. Wansbrough-Jones to the contribution of the Services themselves to science: progress would not have been possible had not the technical and scientific knowledge and appreciation within the Services been greater than is commonly admitted. Moreover, since the War, the Services have also made advances in their own technical education. The old scientific isolation of the Government scientist has gone, and there is a good interchange both of people and results. Nor does Dr. Wansbrough-Jones think that a turnover of young scientific men, due to the attraction of higher salaries in industry, is a bad thing, provided it is not overdone. Many men who could command far higher salaries outside the Government service remain within it on account of the excellent facilities provided. Equipment in the Government Research Establishments is first-class, and he thought that much of the research and development carried out on behalf of the Services are also of great value to British industry as a whole and to science itself. Provided recruitment of scientific men of the right quality and the scientific education of the Services continue, he believes that the harmonious working of the Service and scientific staffs will continue, and that the best use will be made of weapons, and the very difficult task of selecting the right problems to attack will be well done. Research in these fields is admittedly expensive, and though Dr. Wansbrough-Jones agreed that the scientist working for the Services has no easy task in seeing that costs are kept down without lowering the standard of the work, he appeared to be satisfied that Great Britain is getting good value from the average cost for fully-trained research worker, scientist or engineer—an average cost materially smaller than the latest American figures.

# THE CONCEPT OF PHOSPHATE BOND-ENERGY

By Dr. R. J. GILLESPIE, Dr. G. A. MAW and C. A. VERNON

William Ramsay and Ralph Forster Laboratories, University College, London

Department of Biochemistry, St. Thomas's Hospital Medical School

DURING the past twenty years, it has become apparent that phosphorylation is one of the most fundamental processes occurring in living tissue. The role in metabolism of substances which bring about phosphorylation, such as adenosine triphosphate (ATP), is currently interpreted in terms of concepts first elaborated by Lipmann[1], who divided biologically important phosphoric acid derivatives into two groups depending on whether their standard free energy of hydrolysis is large ($c.$ $-$ 12,000 cal. mol.$^{-1}$) or small ($c.$ $-$ 2,000 cal. mol.$^{-1}$). Compounds in the first group are said to contain an 'energy-rich' or 'high-energy' O—P or N—P bond; those in the second group an 'energy-poor' or 'low-energy' O—P or N—P bond. Cleavage of 'high-energy' bonds is imagined to liberate large amounts of free energy which may be used by the organism either to carry forward energetically unfavourable reactions or for the production of work. Catabolic processes are said to be so organized as to lead to the production of 'energy-rich' compounds (for example, phosphocreatine and phosphoarginine), which function as stores of readily available energy. Anabolic processes then proceed by utilizing this energy through the mediation of adenosine tri- and di-phosphates.

This concept of 'energy-rich' phosphate bonds (which is frequently used in its literal sense) is irreconcilable with physicochemical principles. Furthermore, since the theory is actually based on free energies of hydrolysis, the relevance of classical thermodynamics to the interpretation of the detailed mechanisms of biological systems requires scrutiny.

When separate atoms combine to form molecules, that is, when chemical bonds are formed, the total energy of the system *decreases*. The reverse process, the dissociation of a molecule into its constituent atoms, therefore requires an expenditure of energy which is referred to as the heat of atomization. For a diatomic molecule, the bond-energy of the only bond present is defined as being equal to the heat of atomization, that is,

$$\Delta H \text{ for the process } X_2 \rightarrow 2X.$$

A high bond-energy, that is, a large value for $\Delta H$, indicates a strong bond and, conversely, a low bond-energy indicates a weak bond.

In a polyatomic molecule it is usually assumed that the bond-energy of a given bond is independent of its molecular environment[2], and that individual bond-energies are strictly additive. Bond-energies defined in this way, however, are no more than a convenient, although arbitrary, method of dividing up the total heat of atomization. A more useful quantity is the bond-dissociation energy, which is equal to the heat content change $\Delta H$ for the reaction $R:S \rightarrow R\cdot + S\cdot$, where $R\cdot$ and $S\cdot$ are free radicals or atoms. This quantity, unlike the bond-energy, depends on the molecular environment (cf. the O—H bond in HO, $H_2O$ and $H_2O_2$)[3], but can be measured for bonds in polyatomic molecules only in a few special cases and under special conditions.

However, the important point for our present discussion is that bond-energies are always *positive*, that is, energy is always required to break a chemical bond. It is impossible for any simple bond-dissociation process to be energy-producing, and the concepts of 'energy-rich' bonds and the storage of energy in bonds are physically meaningless. It must also be pointed out that even if the correctly defined bond-dissociation energies of different O—P and N—P bonds could be measured, which at present is not the case, they would not, in general, bear any simple relationship to the free energies of hydrolysis, since other quantities such as the energies of formation of new bonds, the heat of ionization and solvation of all the reactants and products and the total entropy change accompanying the reaction, are also involved.

As an example of the current literal use of the term 'phosphate bond-energy' we may quote the following extract: "The removal of the elements of water from phosphoglyceric acid results in structural alterations within the molecule. These are attended by a redistribution of the intrinsic free energy of the system leading to a 'concentration' of free energy in the neighbourhood of the phosphate radical; in other words, to the generation of a new energy-rich bond. The free energy of this new bond has been estimated at about 16,000 cal., i.e., rather more than is required to form a new bond in ATP. This new bond energy, together with the phosphate radical, is then transferred to ADP and a new molecule of ATP is thereby produced"[4]. It is clear, however, that it is impossible for energy to be stored in a bond in this way, since what is meant by a chemical bond is inseparable from the idea of energy release on its formation. Clearly it would be less misleading and more correct to avoid the terms 'energy-rich' and 'energy-poor' bonds and refer simply to high and low free energies of hydrolysis.

In discussing the real significance of the free energies of hydrolysis of biologically important phosphoric acid derivatives, it must first be emphasized that there seems to be little justification for the customary division of these free energies of hydrolysis into two sharply defined groups. Not only is there a wide scatter in the quoted values[5], but also many of them have been obtained by indirect calculations[1] the reliability of which is difficult to assess.

Considerable confusion seems to have arisen in the biochemical literature from a misunderstanding of the significance of the thermodynamic functions, heat content $H$ and free energy $G$, and much of this is directly due to the use of the 'energy-rich phosphate bond' nomenclature. We shall consider some typical examples. The first concerns certain experiments by Lipmann[6], who observed that under particular conditions the condensation of amino-acids to give peptides is accompanied by the hydrolysis of adenosine triphosphate. Citing this as an example of the energy from an energy-rich bond promoting biologically important synthesis, Lipmann concludes that, since only one peptide linkage (free energy of hydrolysis c. − 3,000 cal.) is formed for every molecule of adenosine triphosphate hydrolysed (free energy of hydrolysis c. − 12,000 cal.), the utilization of the phosphate bond-energy is only 25 per cent, the remainder (that is, −9,000 cal.) being 'spilled over' and dissipated as heat. Let us examine the real significance of these figures. The two free energies of hydrolysis quoted are, in fact, standard free energy changes, and from these, assuming for the purposes of this discussion that they are correct, can be calculated the standard free energy change associated with the overall reaction (c. − 9,000 cal.). This will not in general be equal to the actual free energy change $\Delta G$ associated with the reaction as it occurs in an organism, because this quantity is dependent on the concentrations or, more correctly, on the activities of the reactants and products, and is related to the standard free energy change $\Delta G^0$ (reactants and products in their standard states) by the relation

$$\Delta G = \Delta G^0 + RT \log J,$$

where $$J = \frac{(a_M)^M (a_N)^N \ldots}{(a_B)^b (a_C)^c \ldots}$$

for the general reaction

$$bB + cC + \ldots = mM + nN + \ldots$$

where $a_b$ is the activity of $B$, etc.

In any event, even if the actual free energy change were − 9,000 cal., the heat of reaction would in general have a different value. If the reaction occurs under such conditions that the only work done is work of expansion against a constant pressure, then the heat absorbed will be given by the heat content change $\Delta H$, but not by the free energy change $\Delta G$. Unless the entropy change $\Delta S$ is zero, these two quantities will have different magnitudes and may even be of opposite sign. In the more general case where other forms of work than expansion against a constant pressure are done, the heat absorbed will not be given by the heat content change but will depend on the reaction path. Clearly it is incorrect to conclude that the standard free energy change of − 9,000 cal. for this reaction corresponds to the heat liberated, or that it is the actual free energy change associated with the reaction as it occurs in a biological environment. It is difficult to attach any meaning to the statement that the efficiency of utilization of phosphate bond-energy is only 25 per cent. This implies that the reaction might in principle be carried out with a much smaller free energy decrease. However, a different free energy change will only be possible if the reaction has a different stoichiometry and therefore a different mechanism. Whether or not such an alternative process would be possible under any given conditions can only be decided by kinetic and not by thermodynamic considerations.

Some of the confusion in the use of the thermodynamic function $G$ can undoubtedly be attributed to its rather misleading name, free energy, which has led to it being erroneously identified with the energy function $E$. For example, some authors appear to think, possibly because free energy changes are usually expressed in calorie units, that the free energy change associated with a chemical reaction must in some way 'appear' either as work or as heat liberated or as both. The standard free energy change of a chemical reaction $\Delta G^0$ is probably best thought of as a disguised equilibrium constant, the two quantities being related by the expression:

$$- \Delta G^0 = RT \log_e K.$$

Since, in the case we are considering, the standard free energy change for the overall reaction is − 9,000 cal., we may conclude that the position of equilibrium lies well over on the side of the products. However, in deciding whether or not a reaction will, in fact, proceed under any given conditions, thermodynamic considerations are largely irrelevant. Thus, although the position of equilibrium of a reaction may be very favourable, it will only proceed if it has a sufficiently low activation energy; this is not related to the free energy change and will, for example, be considerably influenced by the presence of catalysts. If a reaction has a positive standard free energy change, that is, if the position of the equilibrium is unfavourable, it may still proceed readily if the concentrations (or activities) of the products are kept very small[7]. This may occur, for example, if the reaction is followed by another very fast reaction which removes the products as soon as they are formed, or if they are removed by diffusion through a membrane, or in any of many other possible ways.

It is difficult to understand why it should be considered on the basis of thermodynamic considerations alone that a substance such as adenosine triphosphate, which is said to contain an 'energy-rich' phosphate bond, is necessary to promote the synthesis of a peptide linkage when it is evident that any phosphate with a free energy of hydrolysis more negative than − 3,000 cal. would give an overall reaction with a negative free energy change, that is, with a favourable position of equilibrium. Although thermodynamics shows that the position of equilibrium in the supposed synthesis of a peptide linkage by adenosine triphosphate lies well over on the side of the products, it does not, and in fact cannot, tell us why adenosine triphosphate is particularly effective in this reaction. The reason for this must be sought in terms of kinetic rather than thermodynamic considerations.

Among other types of reactions which should be considered in kinetic rather than in thermodynamic terms is, for example, the enzyme-catalysed transphosphorylation of glycerol by glucose-1-phosphate. In this system, in the absence of the acceptor molecule, the enzyme causes rapid hydrolysis of the glucose-1-phosphate. To quote: "It might have been anticipated, therefore, that hydrolysis rather than transfer, would always occur in the presence of a transferring phosphatase. Apparently, however, the available free energy is not lost all at once; rather does it seem that free energy tends when possible to escape in stages"[8]. Presumably the true explanation here is that the rate of phosphorylation of glycerol by glucose-1-phosphate is greater than the rate of hydrolysis of the latter. To explain the phenomena in terms of a hypothetical desire of free energy to escape in small amounts is a necessarily sterile approach and can contribute nothing to a real understanding of the reaction.

It is often stated that the synthesis of adenosine triphosphate from adenosine diphosphate, which is associated with a standard free energy change of approximately − 12,000 cal., must be coupled with another reaction, which is said to drive the adenosine triphosphate synthesis, for which the standard free energy change is negative and numerically equal to or greater than 12,000 cal. Any difference between the two values is said to be dissipated as heat. It should be clear from the preceding discussion that the synthesis of adenosine triphosphate from the diphosphate does not require immediate coupling of this reaction with another having a greater negative standard free energy change; but rather must the activities of all the reactants and products be such that the movement of the system towards equilibrium will cause the reaction to occur, and that suitable catalysts must also be present so that paths are open by which the reaction can proceed sufficiently rapidly. It will obviously lead to incorrect conclusions if one attempts, as is often done, to link the synthesis of adenosine triphosphate with only those reactions which have a sufficiently large negative free energy change. For example, it has been concluded that, since the standard free energy change accompanying the oxidation of β-hydroxybutyrate by diphosphopyridine nucleotide is of the order of 1,000 cal., phosphorylation of adenosine diphosphate to the triphosphate cannot occur simultaneously with the former reaction. In fact, this may not be the case. The standard free energy change, and indeed thermodynamics in general, gives little information on this point.

In conclusion, we should like to stress the present need for a kinetic approach to the whole problem of phosphorylation reactions. It is clear that substances such as adenosine triphosphate are able to induce phosphorylation rapidly and selectively under a wide variety of conditions. The mechanisms by which these processes occur appear to be largely unknown. It is, however, by the study of these mechanisms, particularly in relation to the enzymes involved, and not by the invention of fictitious kinds of bond-energy, that the role of adenosine triphosphate in phosphorylation reactions will be understood.

We wish to thank Profs. E. D. Hughes and C. K. Ingold for their help and encouragement, Prof. R. A. Morton and Dr. J. Glover for helpful criticism of the manuscript, and Drs. C. A. Bunton, E. M. Crook, P. B. D. de la Mare, Allan Maccoll and P. J. Syrett for many valuable discussions. [Feb. 13.

# β-FORMS OF FIBROUS PROTEINS AND SYNTHETIC POLYPEPTIDES

By Dr. C. H. BAMFORD, L. BROWN, Dr. A. ELLIOTT, W. E. HANBY and I. F. TROTTER

Research Laboratories, Courtaulds, Ltd., Maidenhead and Coventry

We have recently examined the X-ray reflexions from the shorter spacings in some synthetic polypeptides and fibrous proteins, with the view of determining as accurately as possible the axial repeat distance, particularly for the extended polypeptide configuration.

Silk suture or a bunch of fibres from *Bombyx mori* photographed with a cylindrical camera with the fibres horizontal and tilted at about 42° to the X-ray beam gives a diagram in which there is an exceedingly strong arc corresponding to a spacing of 1·156 A. in the direction of the fibre axis. This is probably similar in origin to the 1·2 A. reflexion which Bunn and Garner[1] found by the same technique in oriented fibres of nylon 66, and owes its intensity to the approximately constant succession of scattering atoms along the extended chain. It is the sixth order of the axial repeat in silk (7·04 A. according to McNicholas[2]). On this basis, a more accurate value of the axial repeat is obtained from the 1·156 A. spacing than from other reflexions on layer lines. We consider, therefore, that the best value for the c-axis in our specimens is 6 × 1·156 = 6·94 A. For tussah silk the corresponding reflexion is at 1·153 A., which gives a c-axis repeat of 6·92 A.

The 1·156 A. reflexion should be characteristic of all extended or nearly extended polypeptide chains, and we accordingly looked for it in swan quill and in steam-stretched bristle and hair and in several synthetic polypeptides in the β-configuration. The expected reflexion, weaker relatively than in silk, was found in stretched pig bristle at 1·104 A., giving an axial repeat of 6·62 A. in agreement with Astbury and Street's value for stretched hair[3]. A somewhat diffuse reflexion was observed in stretched horse hair, corresponding to the same spacing. However, no indication whatever of the 1·1 A. reflexion in swan quill (or of one at 1·5 A.) was found on heavily exposed photographs taken under similar conditions to those which showed these reflexions in other polypeptides and proteins.

The synthetic polypeptides, polyglycine, poly-L-alanine and poly-γ-methyl-L-glutamate, have given results of great interest. In poly-L-alanine (β-form) the orientation was good, and a strong meridional reflexion appeared corresponding to 1·147 A. The c-axis repeat for poly-L-alanine is therefore 6·88 A. In polyglycine the orientation was insufficient to show whether the reflexion at 1·16 A. was on or near the meridian, but we consider this very likely in view of the almost identical meridional 1·156 A. spacing in silk. In the β-form of poly-γ-methyl-L-glutamate a meridional reflexion at 1·138 A. was found, giving a c-axis repeat of 6·83 A. The values of the c-axis repeats for the various polypeptides and proteins are collected in the accompanying table, which also gives the mean residue weights.

| Material | c-Axis (A.) | Mean residue weight |
|---|---|---|
| Polyglycine | 6·96–7 05 | 57 |
| Poly-L-alanine (β-form) | 6·88 | 71 |
| Poly-γ-methyl-L-glutamate (β-form) | 6·83 | 143 |
| Silk (*Bombyx*) | 6·94 | 77 |
| Silk (tussah) | 6 92 | * |
| Pig-bristle (stretched) | 6 62 | 107–116 |
| Swan quill | 6·2 (?) | * |

* The mean residue weights do not appear to be known accurately; that of tussah silk is probably not very different from that of *Bombyx*, while that of swan quill is probably similar to that of wool (c. 110)

Calculations show that for a fully extended polyglycine chain the (006) reflexion has a large structure factor; consequently a strong reflexion on or near the meridian at about 1·2 A. should appear. The 1·16 A. reflexion is the only one in this region which we have observed. If the 1·16 A. reflexion in polyglycine is near the meridian, consideration of possible unit-cell structures strongly suggests that the c-axis has a length between 6·96 A. and 7·05 A. The latter figure corresponds to the maximum stagger between neighbouring chains, leading to a triclinic cell, and the lower figure is for a cell the base of which is normal to the chain axis (this appears to be the case in silk and in poly-L-alanine). If we assume that the chain of polyglycine is fully extended (and hitherto no reasons have been advanced against this assumption), it follows that a fully extended polypeptide chain should have an axial repeat of 6·96–7·05 A., about 4 per cent less than the value 7·23 A. based on measurements on small peptides[4]. An alternative explanation of our results is that the crystallites of polyglycine are composed of *parallel* rather than the conventional anti-parallel, polypeptide chains. In order to form satisfactory hydrogen bonds the chains (assumed in this explanation to have a repeat of 7·23 A. when fully extended) may have to contract so that their identity period becomes about 7 A. or less. We might expect, however, that this arrangement is less stable than the fully extended anti-parallel one, since the full contribution from the 'staggering' of single bonds around Cα is not obtained. A partially collapsed anti-parallel chain configuration is also a possibility, but seems open to the same objection.

Pauling and Corey[5] have stated their view that polypeptide chains will take up specific configurations corresponding to minimum energy of the chain. The fully extended chain is one such configuration; if this has a repeat length of 7·23 A. the next stable configuration (the pleated sheet) has a repeat of 6·68 A., and configurations of intermediate repeat length should be unstable. This point of view, however, does not take any account of energy from interchain forces other than those involved in hydrogen bonds.

If a fully extended polypeptide has a repeat of about 7 A., the next stable configuration should have a repeat about 6·4 A. It is quite certain that poly-L-alanine (which according to Pauling and Corey should form a pleated sheet by reason of steric hindrance of the methyl groups) has a c-axis repeat of 6·88 A. (or a multiple of this), and cannot therefore take up the pleated-sheet configuration. The small contraction compared with polyglycine suggests that steric hindrance is accommodated, but that no contraction to a specific configuration (involving staggering of single bonds around the Cα atoms) takes place. This may mean that the effect of methyl-group steric hindrance has been over-estimated by Pauling and Corey, and also that the energy of the whole crystalline system may be at a minimum even though the individual chains are not in the position of lowest energy. The alanine content of tussah silk is reported to be higher than that of *Bombyx mori*, and it is therefore interesting to note that the c-axis repeat in tussah is intermediate between that of poly-L-alanine and *Bombyx*.

The result obtained with swan quill is surprising. This material shows infra-red dichroism of the type associated with a β polypeptide[6], but very much less marked than in silk. It might be thought that part of the structure consisted of α-chains at right angles to the fibre axis, but we have been unable to detect a 1·5 A. reflexion either on the meridian or the equator. The large number of sharp reflexions in the centre of the diagram (similar to sea-gull quill[7]) shows that parts of the structure are highly oriented. If the 3·1 A. meridional reflexion in swan quill indicates a unit cell with c = 6·2 A., then calculation shows that the 1·03 A. reflexion in such a contracted structure would be weak. This may perhaps explain our failure to observe such a reflexion. If this explanation be correct, it furnishes some evidence for planar or nearly planar amide groups in feather keratin, for the low calculated intensity of the 1·1 A. reflexion for a slightly contracted chain is a result of rotation assumed to be around the Cα single bonds only. The effect of this rotation is to destroy the approximately equal succession along the chain axis of atoms in the backbone.

The table shows that the fibre repeat-distances in the β-forms of the synthetic polypeptides and in the silks are surprisingly similar considering the wide variations in the size of the side chains. Such variations as are found may be attributed to the presence or absence of a β-carbon atom, rather than to the total bulk of the side chains. It is therefore surprising that the *c*-axis repeats of the β-keratins are so much smaller, and we conclude that the character of the side chains is more important in this respect than their mere size.

In conclusion, we consider that the observations briefly set out above suggest that we are not yet in a position to calculate with precision the arrangement of the polypeptide backbone of these large molecules. If this is the case when we are concerned with regions of high crystallinity, it is still more true of the amorphous parts which make up by far the greater part of many fibrous proteins, and of all proteins in solution. # NATURAL CONFIGURATION OF THE PURINE NUCLEOTIDES IN RIBONUCLEIC ACIDS

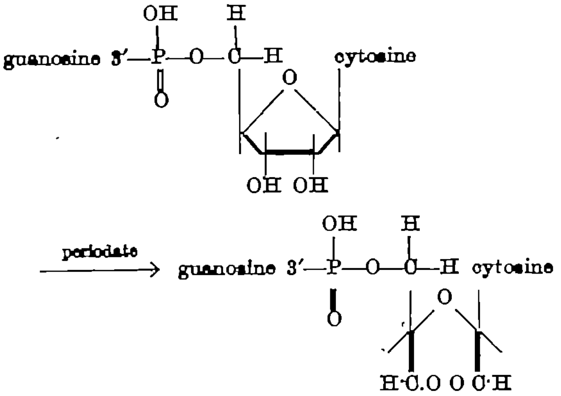
## Chemical Hydrolysis of the Dinucleoside Phosphates

WHEN hydrolysed by means of cold alkali or acid, the ribonucleic acids give rise to mixtures of isomeric nucleotides, the *a* and *b* nucleotides of Carter[1] and Cohn[2], which are the 2′- and 3′-phosphates of the four nucleosides, probably in that order which we shall assume for convenience. In the intact nucleic acids, these substances are linked to each other largely or possibly entirely by phosphate diester bridges also involving the 5′ OH group in the nucleosides. It is known, however, that acid or alkaline hydrolysis effects the degradation of ribonucleic acid through intermediate cyclic phosphate compounds involving both the 2′- and 3′-positions in the nucleoside residues[3,4], so that the final position of the phosphate residue in the nucleotide liberated is no certain guide to its position in the intact nucleic acid. Similarly, in ribonuclease digestion, the fact that the pyrimidine nucleotides liberated are all of the *b* (3′)-type[5] is not definite proof that the 3′-link is involved in the intact nucleic acid, because the enzymic degradation also goes through a cyclic step and so phosphate migration may also take place in this case.

The original object of this work was to degrade relatively simple compounds derived from ribonucleic acid in order to determine the actual configuration in the internucleotide link, and the dinucleotides resulting from exhaustive ribonuclease digestion[6] seemed to be the most profitable substances to investigate. These are composed of a purine nucleoside joined at C 2′ or 3′ by a phosphate diester bridge to the 5′-group of a pyrimidine nucleoside 3′-phosphate. This type of compound is resistant to snake venom phosphodiesterase, but if the pyrimidine nucleotide residue is dephosphorylated at C 3′, this enzyme then breaks the resulting dinucleoside monophosphate to give a pyrimidine nucleoside 5′-phosphate and a purine nucleoside. Our aim was to attempt to induce the enzyme to break the other end of the phosphate bridge, so as to leave the phosphoric acid joined either at C 2′ or C 3′ without the intervention of a cyclic intermediate. At this point we should state that we did not succeed in this object, but instead we discovered a chemical method for accomplishing this degradation.

As an example of this degradation we shall take the case of the dinucleotide of guanine and cytosine. This was dephosphorylated by prostate phosphomonoesterase to give a dinucleoside monophosphate.



On treatment with sodium periodate, the cytidine residue was split between C 2′ and C 3′ to give a dialdehyde derivative. This substance may be isolated from excess periodate and iodate by chromatography in *iso*propanol – ammonia[4].

When treated at *p*H 10 with Russell viper venom for 6 hr. at 37° C. and rechromatographed in the same solvent, two substances were detected. The one with the higher $R_F$ value was eluted and found to have an absorption spectrum similar to, but not identical with, that of cytosine. The slower-moving compound, which had the same $R_F$ as guanylic acid, was eluted, and on chromatographing in an ammonium sulphate – sodium acetate – *iso*propanol – water solvent[4] was found to be guanylic acid *b* exclusively, and its identity was confirmed by an examination of its absorption spectrum.

Control experiments, however, gave the same result; that is, it was possible to obtain guanylic acid *b*, together with the cytosine-containing compound (which, incidentally, does not seem to be identical with the substance obtained by the action of periodate on cytidine), from the dialdehyde derivative of the dinucleoside monophosphate of guanine and cytosine without the addition of snake venom, but simply by incubation at *p*H 10. Further experiments confirmed that this action was independent of a diesterase and occurred under conditions in which cyclic nucleotides are completely stable. Apparently the dialdehyde derivative of a dinucleoside monophosphate is unusually unstable to alkali, and we find that a certain amount of splitting actually takes place even on chromatographing in *iso*propanol – ammonia.

This method has also been applied to the degradation of the dinucleoside monophosphates obtained from guanylyl uridylic acid, adenylyl cytidylic acid and adenylyl uridylic acid, and in each case the dialdehyde derivative yielded, on mild alkaline treatment, either guanylic acid *b* or adenylic acid *b*. Thus both purine nucleotides occur in the dinucleotides (and presumably in ribonucleic acid) as the *b* isomers, which are probably the nucleoside 3′-phosphates.

The possibilities of this procedure, by means of which the phosphate terminal nucleotide of a dinucleotide may be removed, are at once apparent. The conditions under which the experiment is carried out are so mild that any polynucleotide would be quite stable, and by a repetition of the procedure it should be possible to determine the nucleotide sequence in a polynucleotide chain. As the next step we intend to apply the method to the investigation of trinucleotides.

## Enzymatic Splitting of Purine Internucleotide Linkages

THE nature of the phospho diester internucleotide linkages involving purine residues of ribonucleic acid has not been previously demonstrated. In the preceding communication, it was decided that purine nucleotides occur in ribonucleic acid as the *b* isomers. We have reached the same conclusion from enzymatic studies with a spleen fraction. Volkin and Cohn[1] had already isolated *b* nucleotides of all the bases after digestion of ribonucleic acid with a crude spleen extract[2]. However, this did not establish the position of the phosphoryl group (2′- or 3′-) in the original diester, since the occurrence of nucleoside 2′ : 3′-phosphates as intermediates was not ruled out. These cyclic compounds, if formed in the course of hydrolysis, would allow the possibility of phosphoryl migration. In the present investigation, we have found that guanylic acid *b* and adenylic acid *b* resulted from the digestion of the ribonuclease-resistant 'core' with a fraction from spleen, and no cyclic compounds were observed at any time. Furthermore, it has been shown that the cyclic mononucleotides were quite slowly attacked by the enzyme and therefore would have accumulated, had they been intermediates.

The enzyme preparation was one of several fractions previously separated from calf spleen[3]. Fresh tissue was homogenized in cold 8·5 per cent sucrose, adjusted to *p*H 5 and centrifuged. The precipitate was washed with 8·5 per cent sucrose and then with acetone (— 10°). From the dry acetone powder it was possible to extract the enzyme activity in soluble form with 0·2 *N* acetate buffer, *p*H 6. The extract was fractionated with ammonium sulphate at *p*H 5 and again at *p*H 8.

This fraction was incubated with 'core' prepared from ribonucleic acid by exhaustive digestion with ribonuclease followed by dialysis against tap water. Both yeast and turnip yellow mosaic virus were used as sources of ribonucleic acid. At least 90 per cent of the purine residues of 'core' were liberated as *b* nucleotides, as determined by paper chromatography[4]. No cyclic intermediates were found at any time during the digestion.

Now it was necessary to establish that our failure to observe cyclic mononucleotides was not due to their being rapidly hydrolysed. Accordingly, we compared the rate of formation of purine mononucleotides from 'core' with the rate of hydrolysis of cyclic guanylic and adenylic acids. The incubations were carried out at 37° in a total volume of 1 ml., containing 80 μmoles of potassium phosphate buffer, *p*H 7·4, 0·3 mgm. of spleen fraction and substrate. As an example, 9·6 μmoles of guanylic acid *b* were derived from 5 mgm. of 'core' in 1 hr. During this time, 1·8 μmoles of guanosine 2′ : 3′-phosphate were hydrolysed to the extent of only 16 per cent, and 0·3 μmole was split to the extent of 70 per cent. Clearly, the guanylic acid was not formed by way of guanosine 2′ : 3′-phosphate. Under these conditions, the cyclic compound would be expected to accumulate because of its slow rate of hydrolysis, but none was detected. In parallel experiments 0·3 and 0·6 μmole of guanosine 2′ : 3′-phosphate was actually added to a mixture of 'core' and enzyme. Hydrolysis of 'core' proceeded, and most of the added cyclic compound survived an hour's incubation. Cyclic adenylic acid was somewhat more rapidly split by the spleen preparation, but its accumulation could also be expected, had it been formed as an intermediate.

Similar observations were made with the dinucleotides of guanine and cytosine, guanine and uracil, adenine and uracil, and adenine and cytosine. Preparation of these compounds is described elsewhere[5]. All were split to give *b* nucleotides of purine bases, without the appearance of cyclic mononucleotides. Again, as an example, 1·25 μmoles of the dinucleotide of guanine and cytosine were hydrolysed to the extent of 85 per cent in 1 hr., with no accumulation of guanosine 2′ : 3′-phosphate. Under similar conditions, 1·3 μmoles of guanosine 2′ : 3′-phosphate were incubated with spleen fraction and 50 per cent still remained after 3 hr.

From these findings we conclude that the purine nucleotide residues in ribonucleic acid occur largely in the *b* form.

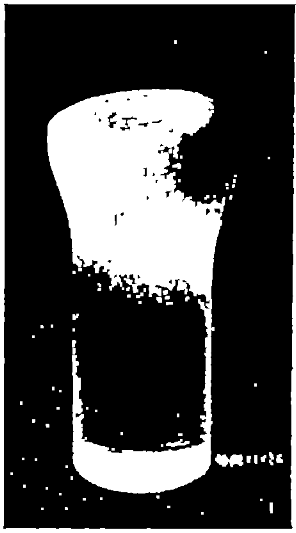
## Breakdown of Methyl Methacrylate Polymer by High-Energy Radiation

THE behaviour of polymethyl methacrylate ('Perspex') when exposed to high-energy radiation is markedly different from that of many other long-chain polymers such as 'Polythene' and polystyrene[1]. These latter develop cross-links forming a thermosetting material, whereas polymethyl methacrylate shows rapid breakdown after relatively short radiation doses. The nature of the changes produced is complex, and appears to vary with the temperature as well as the radiation dose.

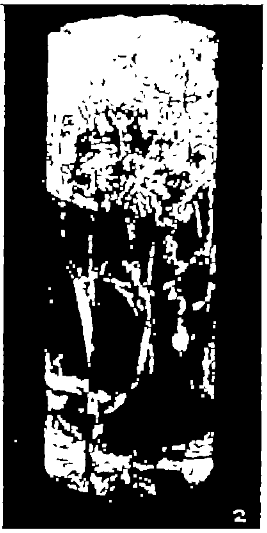
Most of the irradiation work was carried out in the BEPO atomic pile at Harwell, at a temperature of about 70° C. Unit radiation dose is defined as a flux of $10^{17}$ slow neutron/cm.$^2$ plus the associated fast neutrons and gamma-rays. After exposure to some two units of radiation 'Perspex' loses its transparent appearance, expands and forms a white brittle material, consisting of a mass of bubbles. Higher radiation doses produce a white powder. If shorter radiation doses are given, there is no obvious change in the 'Perspex', apart from a yellowish tint which occurs in many organic compounds exposed in the pile. When these specimens are afterwards heated, internal bubbling occurs and the material expands to six to eight times its original volume. The temperature at which this change occurs is determined by the radiation dose—the nearer the radiation dose approaches 2 units, the lower the subsequent temperature needed to produce bubbling. Thus a radiation dose of only 0·1 unit is needed for bubbling to occur at a temperature of 140° C. This phenomenon is ascribed to the breakdown of the side-chains, releasing mainly carbon monoxide and dioxide and hydrogen. These are maintained under pressure inside the material until the temperature rise weakens the material sufficiently to allow bubbles to form.

An interesting observation is that bubbling does not occur within a distance of about 1 mm. from the free surface of a specimen. In this region 'Perspex' remains transparent, and tough. The expanded material therefore consists of an internal network of bubbled material surrounded by a thin and tougher coat. To explain the losses of weight observed in 'Polythene' on irradiation[2], it was necessary to assume that certain gases produced by radiation can only escape from the polymer if they are liberated within a small distance from the surface. In the present work on polymethyl methacrylate, this assumption has been justified. Thus a specimen irradiated for 1·1 units, and afterwards heated for a short time to produce a small amount of bubbling, had a 'free zone' (without bubbles) about 1 mm. in thickness and following the surface contours. This free zone is not due to some form of low-penetrating radiation nor to the presence of oxygen. The assumption of diffusion over a limited distance must therefore be accepted.

The same effect has been produced by irradiation with pure gamma-radiation from a cobalt-60 source. Fig. 1 shows a rod of 'Perspex', irradiated in a non-uniform γ-flux, and afterwards heated to produce bubbling. The end of the rod subjected to the highest radiation dose shows considerable expansion, whereas the opposite end is apparently unaffected. If the radiation takes place at 20° C., considerable doses can be absorbed without any obvious effects on the specimen. If it is then left standing for several months, intense cracking appears in the specimen, but no bubbling (Fig. 2). It would therefore appear that temperature above the second-order transition is needed for large-scale gas diffusion to take place.



1



2

One may perhaps envisage irradiated 'Perspex' being used as a heat-insulating material. Small blocks of the polymer can be placed inside a vessel and, by heating, expanded *in situ* to give a bubbled material filling the required volume.

Fuller details will be published elsewhere[3].

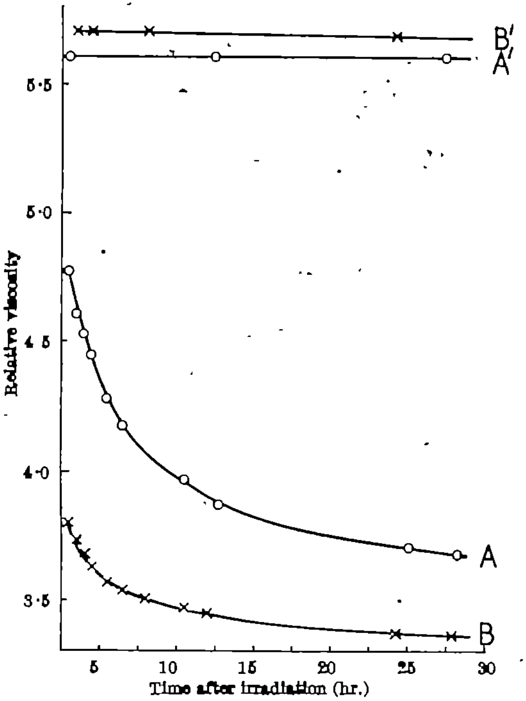
## 'After-effect' in Aqueous Solutions of Deoxyribonucleic Acid Irradiated with X-Rays

IT has been known for some time that the irradiation of aqueous solutions of deoxyribonucleic acid with X-rays leads to a loss of viscosity[1]. However, apart from any drop in viscosity during the irradiation, it has been observed by several workers[1,2] that there is also an 'after-effect' in these solutions, namely, a slow decrease of viscosity which continues for some time after the actual irradiation.

Although recent work[3] has to a large extent clarified the nature of this after-effect, a certain amount of confusion still exists with regard to its extent under different experimental conditions. Butler and Conway[4] have stated that the after-effect is only observed when molecular oxygen is present in the solution during the irradiation, and they have suggested that the effect is due to a slow decomposition of a peroxidic derivative of the deoxyribonucleic acid which is formed by the $HO_2$ radicals present under these conditions. At first these authors concluded that the substance formed was similar to a dialkyl-peroxide. However, in a subsequent



Change of viscosity of 0·1 per cent aqueous solutions of thymus deoxyribonucleic acid (Signer) after irradiation with X-rays (200 kV.). Total dose, 6,000 rep. (dose rate, 1,000 rep /min.). Curve *A*, Irradiation in the presence of atmospheric oxygen; curve *B*, irradiation *in vacuo*. *A'* and *B'* refer to the corresponding unirradiated control solutions

publication[4] they reported the presence of hydrogen peroxide and suggested that hydroperoxides were formed by the reaction between deoxyribonucleic acid and $HO_2$ radicals and that the latter are solely responsible for the after-effect.

Contrary to this view, we have always considered that the after-effect in deoxyribonucleic acid solutions is due to a slow hydrolysis of labile substances (for example, labile phosphate esters) which are formed from the deoxyribonucleic acid, particularly by the oxidizing radicals produced in the irradiation process. However, on this basis it would be difficult to understand that the after-effect should only occur in the presence of molecular oxygen, because it is well known[5] that (oxidizing) OH radicals are also present in evacuated solutions, as they are formed by the action of the ionizing radiation on water (equation 1).

We have therefore irradiated deoxyribonucleic acid solutions, under oxygen-free conditions, and have, in fact, observed a definite after-effect on the viscosity. The accompanying graph shows the results obtained for a highly polymerized 'Signer' deoxyribonucleic acid specimen, relative viscosities being determined in an Ostwald viscometer; very similar results were obtained with a number of different samples of nucleate.

In all cases the after-effect *in vacuo* was about one-third of that obtained in the presence of oxygen. Thus, the effect of oxygen is only one of enhancement, and this observation is in complete agreement with experiments on a number of other substances[6] (for example, the formation of acetaldehyde from alcohol, of pyruvic acid from lactic acid and from alanine, etc.), where the ratios of the yields in the absence and presence of oxygen were always found to be between one-third and one-sixth, depending on the substances and on the experimental conditions.

In general, the reaction, in the absence of molecular oxygen, can be explained by the following mechanism ($RH$ = solute):

$$\text{Primary radiation process}^5: H_2O \rightsquigarrow H + OH \quad (1)$$

$$RH + OH \rightarrow R^\cdot + H_2O \quad (2a)$$

$$R^\cdot + OH \rightarrow \text{product} \quad (2b)$$

$$\text{Back reactions}\begin{cases} H + OH \rightarrow H_2O & (3) \\ R^\cdot + H \rightarrow RH & (4) \end{cases}$$

In the presence of molecular oxygen, however, one will have the reactions:

$$H + O_2 \rightarrow HO_2 \quad (5)$$

and

$$R^\cdot + O_2 \rightarrow RO_2^\cdot \rightarrow RO_2H \rightarrow \text{product} \quad (6)$$

Thus the back reactions (3) and (4) may be largely inhibited, leading to an increased yield.

It is therefore clear from the reactions outlined above that, although molecular oxygen is not a decisive factor, nevertheless its presence can enhance very considerably the attack on the nucleic acid.

Our views on the after-effect have been confirmed already to some extent by our recent experiments[7] substantiating our earlier suppositions that labile compounds are formed; we have, in fact, been able to demonstrate the presence of labile phosphate esters in irradiated nucleic acid solutions.

A full account of this work will be published elsewhere. Our thanks are due to Prof. R. Signer for supplying several samples of deoxyribonucleic acid.

## Effect of Nitric Oxide on the Thermal Decomposition of Ethyl Nitrate

We have noted with interest the recent communications of Style *et al.* regarding the reaction between diethyl peroxide and nitric oxide in the gas phase, and the inhibition of the thermal decomposition of diethyl peroxide[1]. It has been customary to assume that nitric oxide inhibits reactions in the gas phase by the removal of active free radicals with the formation of compounds of the type $R$.NO, where $R$ is the radical. As Style points out, however, inhibition by nitric oxide may not necessarily indicate a free radical mechanism.

We have recently made observations in the course of experiments on the thermal decomposition of ethyl nitrate[1] in the presence of nitric oxide which would tend to support this idea. During these experiments, the maximum pressure of nitrogen dioxide attained is never more than 10 per cent or so of the initial pressure of ethyl nitrate. However, if nitric oxide is present initially, the nitrogen dioxide produced is considerably increased and the time at which maximum pressure occurs is markedly reduced. This is illustrated in the accompanying table.

| Pressure of ethyl nitrate (mm. Hg) | Pressure of nitric oxide (mm. Hg) | Max. pressure of nitrogen dioxide (mm. Hg) | Time of nitrogen dioxide max. (min.) |
|---|---|---|---|
| 54·2 | 0·0 | 6·0 | 28 |
| 47·9 | 6·1 | 6·5 | 12 |
| 53·6 | 12·9 | 11·5 | 8 |
| 52·4 | 25·1 | 16·0 | 7 |

These figures are supported by gas analyses at the maxima, and calculation shows that the nitrogen dioxide could not result solely from the thermal fission of the ethyl nitrate. Hence we are led to the conclusion that nitric oxide itself reacts directly with ethyl nitrate, thus:

$$C_2H_5ONO_2 + NO \rightarrow C_2H_5ONO + NO_2 + 5 \text{ k.cal.}$$

In contrast to earlier claims[2], the initial rate of pressure increase in the experiments above is decreased by the same order of magnitude as is observed when nitrogen dioxide is added. This is to be expected, since ethyl nitrate is to some extent rapidly converted to ethyl nitrite, which is known to decompose appreciably slower in the same temperature-range, lowering the overall rate. Some independent evidence that ethyl nitrite is present comes from the work of Levy[3], who, from an infra-red examination of the products of ethyl nitrate decomposition, claims the existence of up to 70 mole per cent of ethyl nitrite.

Full details of our work will be published elsewhere; but it is clear that the above type of reaction involving nitric oxide will have importance not only in nitric ester decomposition, but also in other allied investigations.

## Oscillating Droplets

An increasing amount of work is being carried out on the behaviour of drops of solvent rising or falling in water, in order to investigate the rate-determining steps involved in solvent extraction. Previous work in these laboratories using mutually saturated phases demonstrated that in packed columns the statistical mean volume-surface diameter is proportional to $(\gamma/\Delta\rho g)^{1/2}$ when the packing size is above a critical value[1]. Later experiments have now shown that if the dispersed solvent phase contains an undistributed solute, for example, acetone, the droplets are larger than predicted, whereas no effect is observed if the solute is in the aqueous phase. A smaller increase in size is also obtained when the phases are pure but not mutually saturated.

Since the increase in size could have been caused by an increase in the interfacial tensions in these systems, measurements of the interfacial tensions were made using the pendant-drop method of Andreas *et al.*[2]. The drop was formed with a hypodermic syringe and an enlarged image was projected on to a screen; ciné-photographs were also taken. It was observed that the surfaces of the drops were invariably disturbed by rippling and the drops themselves were subjected to erratic pulsations; in addition, the change in the interfacial tension, if any, measured between pulsations, was in the wrong direction to account for the increased droplet size. It was possible to follow the flow pattern from the refraction lines, and it could be seen that the pulsations were apparently associated with 'shock waves' originating within or on the surface of the drop. These waves passed through the interface, each causing a noticeable amount of transfer. When aluminium powder was suspended in the droplets a violent circulation was seen at the surface of the drop. This behaviour also occurred when the drops were completely detached from the capillary tip and was therefore not due to diffusion of solute from the bulk of the solvent into the drop.

A further investigation of solute transfer to and from droplets was then carried out using as solutes acetone, ethyl alcohol, acetic acid, nitric acid, hydrochloric acid, ferric chloride, cobalt chloride, ceric ammonium nitrate and uranyl nitrate. As solvents, diethyl ether, benzene, toluene, ethyl acetate, methyl *i*-butyl ketone, dibutyl carbitol and nitrobenzene were used. When these solutes passed from a solvent droplet to water, oscillations of the drops were observed in every case except with uranyl nitrate. Oscillations of water droplets suspended in a solvent phase were also observed when the transfer was into the droplets. With uranyl nitrate, oscillations were only obtained when the transfer was in the reverse direction. This suggests that the phenomenon is associated with the heat evolved in transfer, since heat is absorbed when uranyl nitrate passes from a solvent phase to water, whereas heat is evolved by the other solutes. The presence of surface-active materials such as proteins and detergents reduced the effect; this may indicate that the effect of the heat of transfer is to cause local variations in the interfacial tension, thereby disturbing the equilibrium of the droplet.

No oscillations were observed when droplets of pure unsaturated solvents were suspended in water. A slight effect was observed in some cases when organic solutes passed from water to a suspended solvent drop. McBain[3] has earlier reported a somewhat similar behaviour at plane liquid–liquid interfaces, which gives rise to micro-emulsification at the interface.

The present results indicate that the non-turbulent layers adjacent to the interface, postulated by Whitman[4], may be absent in certain conditions, and that the pulsations may be more effective in promoting transfer than molecular diffusion. Since the effect varies considerably from system to system, a comparison of transfer-rates for different systems must be carried out with circumspection.

Thanks are due to Mr. A. S. White for his interest and encouragement in this work, and to the Director,

Atomic Energy Research Establishment, for permission to publish this communication.

# Electronically controlled Spectrographic Spark Source

In the past two decades, various types of high-voltage spectrographic spark sources have been developed, such as the so-called uncontrolled[1], mechanically controlled[2,3], auxiliary spark gap controlled[4,5] and electronically controlled[6-8] types.

In my laboratory a new electronically controlled spectrographic spark source system has been constructed, the wiring diagram of which is shown in Fig. 1. $T$ denotes a high-voltage transformer charging the condenser $C$ through the vacuum diode $V2$. $G1$–$G2$ is a twin spark gap to control the discharge of the condenser $C$.

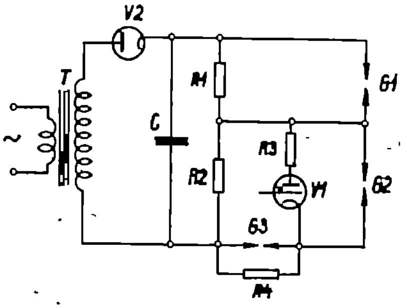

Fig. 1. Wiring diagram of the high-energy electronically controlled spark source. $C$, condenser; $G1$–$G2$, controlling twin spark gap, $G3$, analytical spark gap; $R1$, $R2$, $R3$, $R4$, ohmic resistors; $T$, high-voltage transformer; $V1$, gas-filled triode (thyratron); $V2$, rectifier tube

By means of resistors $R1$ and $R2$, the voltage appearing on the terminals of the condenser $C$ is uniformly distributed to the twin controlling spark gap $G1$–$G2$. $G3$ is the analytical spark gap, shunted as usual by the resistor $R4$. $V1$ is a gas-filled triode (thyratron) normally closed by a negative bias. The spark gaps $G1$ and $G2$ must be adjusted so that their breakdown is safely prevented before applying the firing pulse to the thyratron grid. The role of the ohmic resistance $R3$ will be dealt with later.

The system operates in the following manner. Condenser $C$ being charged to the maximum voltage produced by transformer $T$ during one half-period of the A.C. voltage wave, in the following half-period a positive voltage pulse is applied to the grid of the tube $V1$ closed by the negative bias, in consequence of which the tube fires. Thus, $R3$ being much smaller in value than $R1$ and $R2$ respectively, the lower electrode of spark gap $G1$ comes practically to cathode potential. As the common electrode of the twin spark gap $G1$–$G2$ is at cathode potential, the entire charging voltage of condenser $C$ appears on the electrodes of $G1$, which will break down owing to the approximately double voltage obtained. Then condenser $C$ begins to discharge through $G1$, the ohmic resistors $R3$ and $R4$ and the tube $V1$. As $G1$ is practically short-circuited owing to the breakdown previously mentioned and the resulting current flow, the greater part of the voltage on the terminals of condenser $C$ appears on the terminals of $R3$ and the spark gap $G2$ respectively, in consequence of which the latter also fires. $R3$ is assumed to be much larger in value than $R4$. After the breakdown at $G2$, the voltage on the terminals of condenser $C$ appears on those of resistor $R4$ and the analytical spark gap $G3$ respectively, so that the latter also breaks down. Now the discharge of condenser $C$ continues through $G1$, $G2$ and $G3$. The spark gaps $G2$ and $G3$ being broken down, the voltage on the terminals of the ohmic resistor $R3$ consists only of the arc voltage of $G2$, where the current flow will be quite negligible. Tube $V1$ is extinguished either at the end of the discharge of condenser $C$ or, if the frequency of the circuit is low, before the end of the discharge. This depends on the electrical characteristics of circuit $C$–$G1$–$G2$–$G3$ where, according to the requirements of the analysis, a self-inductance and an ohmic resistor can also be inserted.

The positive voltage pulses necessary to control tube $V1$ are supplied by means of a mechanical switch or electronically[8]. In the arrangement of Fig. 1, sparks can be produced at the rate of the mains voltage frequency or at a lower rate. Controlling the grid of $V1$ by means of a pulse generator, the number of sparks per second can be any subharmonic frequency of the mains. If the circuit in Fig. 1 is appropriately adjusted, the number of discharges per second can be twice as great, or more than the frequency of the mains voltage.

While the electronically controlled spark source in Fig. 1 has been especially devised to produce high-energy sparks, the apparatus in Fig. 2 is used to provide low-voltage condensed sparks and interrupted arcs. $T$, $V2$, $V3$, $C1$, $C2$ are the components of a conventional voltage doubler. Condenser $C3$ producing the actual spark energy is charged through resistor $R4$ from condensers $C1$ and $C2$. The remaining part of the circuit is the same as that of Fig. 1, with the difference that the spark gap $G3$ of Fig. 1 as well as resistor $R4$ are omitted. Condenser $C$ discharges through the spark gap $G1$–$G2$ and the Tesla transformer $A$, the voltage of which ignites the interrupted arc or the low-voltage condensed spark. The grid of the thyratron tube $V1$ can be controlled by any frequency desired.

More detailed descriptions of spark sources of similar design will appear elsewhere at later dates.

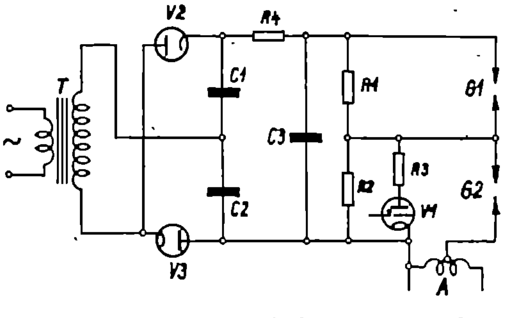

Fig. 2. Low-energy electronically controlled spark source. $A$, Tesla transformer; $C1$, $C2$, $C3$, condensers; $G1$–$G2$, controlling twin spark gap; $R1$, $R2$, $R3$, $R4$, ohmic resistors; $T$, transformer; $V1$, gas-filled triode (thyratron); $V2$, $V3$, rectifier tubes

## Effect of Continued Iron Administration on Growth

During studies on the effects of repeated parenteral administration of iron to mice, rabbits and guinea pigs, various toxic manifestations were observed[1]; but in general there was little effect on growth with either colloidal or diffusible forms of iron. One diffusible iron preparation, namely, 'ferric hydroxide ferrous ascorbate', however, depressed growth markedly. The results obtained with three iron preparations are summarized below.

(*a*) *Colloidal iron.* When iron in colloidal form is given in repeated sub-lethal doses, a large quantity may accumulate in the body before serious harm results. Mice lived two to three months after twelve weekly intravenous doses of 180 mgm. iron per kgm. of saccharated iron oxide, that is, a total dose of 2·16 gm. iron/kgm. There was no loss of weight in these animals until death supervened. The ultimate cause of death is not clear; but severe damage was noted in the lungs, liver and kidneys. Four one-week old mice injected daily with 40 mgm. iron/kgm. of saccharated iron oxide by the subcutaneous route gained weight normally until they reached adult size (seven weeks), the total dose given being 0·9 gm. iron/kgm. of their final body-weight (20 gm.). Two three-day-old guinea pigs injected daily with 40 mgm. iron/kgm. of the same preparation subcutaneously also continued to gain weight much the same as two control guinea pigs.

(*b*) *Diffusible iron.* Diffusible iron preparations behave differently both as regards toxicity and fate in the body, the results obtained depending on the nature of the non-ionized whole molecule of the iron compound[1,2]. Seven young guinea pigs, varying in age from two days to a few weeks and in weight from 75 to 320 gm., were given large doses of diffusible preparations of iron by repeated subcutaneous injections. Four of these received 11·25 mgm. iron/kgm. daily in the form of 'ferric hydroxide ferrous ascorbate', while the remaining three had 30 mgm. iron/kgm. daily in the form of 'ferric chloride caramelate'[1]. The latter group grew and gained weight without obvious deviation from the normal, during the whole period of the injections which lasted 63 days, their final weights being 496, 450 and 465 gm. The first four, however, died after 17, 27, 43 and 63 days respectively. Their growth was interfered with appreciably, and although they continued to increase in weight for a while, the rate of increase soon slowed down. In the case of guinea pigs 3 and 4, serious loss of weight was noted in the last few weeks of life, their final weights being 180 and 175 gm. There were hæmorrhages in the lungs and histological damage in the adrenals in all four guinea pigs.

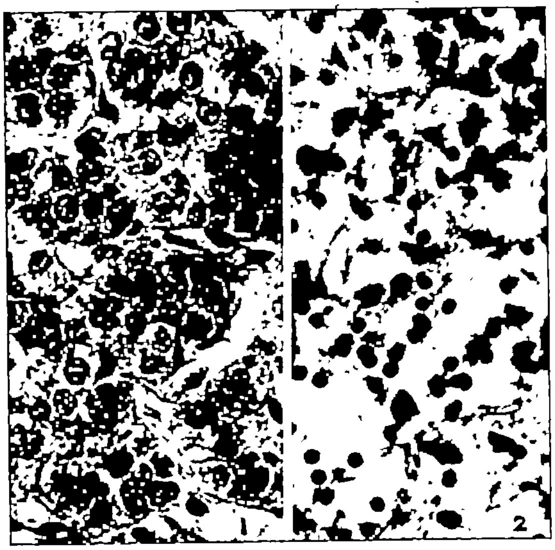

Fig. 1. Anterior pituitary of normal guinea pig showing large vesicular nuclei and abundant cytoplasm. Stained with carmalum. × 500

Fig. 2. Anterior pituitary of guinea pig 4, injected with 'ferric hydroxide ferrous ascorbate'. Section shows numerous pyknotic nuclei and wide spaces between atrophied cytoplasm of cells. Stained with carmalum. × 500

Growth retardation after injections of 'ferric hydroxide ferrous ascorbate' may be secondary to adrenal and lung damage, and could be caused through interference with the normal functioning of ascorbic acid. On the other hand, a direct interference with the functions of the pituitary seems likely. Sections of the pituitary in guinea pig 4 revealed iron staining in the cells of the anterior pituitary—a finding which is recorded in the experimental animal for the first time—and there was histological damage with atrophy of cells and pyknosis of nuclei in guinea pigs 3 and 4 (Figs. 1 and 2). Neither iron staining nor histological injury was detected in the pituitaries of animals receiving saccharated iron oxide or 'ferric chloride caramelate'.

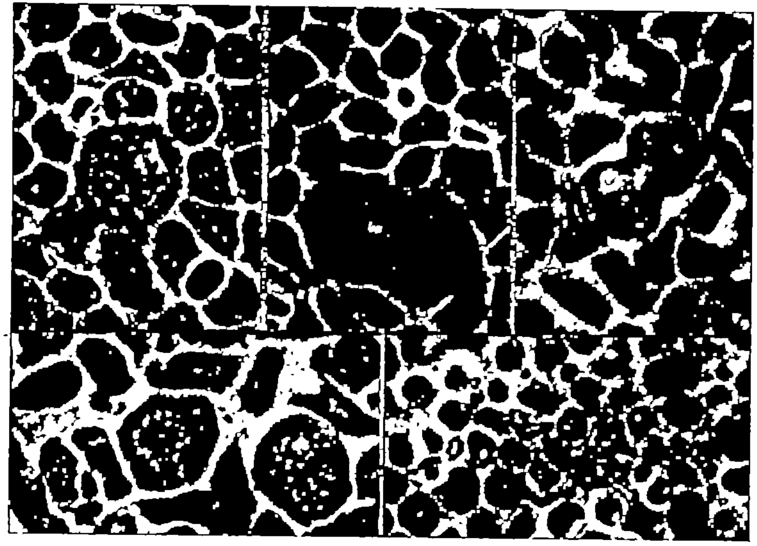
## Effect on Lymphocytes of Ionizing Radiation

The increasing use of radioactive material makes the biological assay of the effects of ionizing radiation of importance. Lymphocytes are agreed to be the most sensitive mammalian cells available for the study of such effects; Trowell[1] has recently published his findings using whole animals and organs. Elsewhere, one of us[2] has described a method whereby human cells can be maintained alive for periods up to fourteen days without the elaboration of traditional tissue culture technique. All that is needed is 3 per cent agar in distilled water, of which 1 c.c. is added to 2 c.c. of equal parts of human serum



All photographs are of living serum agar cultures of human lymph glands. Phase contrast. × 1,400

Figs. 1-4. Mitosis in non-irradiated cultures, the photographs are of different cells

Fig. 5. Culture 24 hr. after irradiation with 90 r.

and Tyrode's solution. Small squares of agar are cut out of poured plates, and mounted on microscope slides. If human lymph glands are scraped with a scalpel, the resultant juice may be planted on this agar; a cover-slip is applied and the preparation is sealed with paraffin wax. The lymphocytes move actively at 37° C., and several types of cells may be recognized; some of these proceed readily to mitosis.

A small radium applicator mounted in lead has been used so that 350 r. of gamma radiation could be administered per hour to the culture. Within one hour of the application of 350 r., marked nuclear changes occur in the small lymphocytes; larger cells, probably from the reticulo-endothelial system, are not affected. The lymphocytes become progressively less motile, and most of them necrose within twenty-four hours after a series of nuclear changes. Controls survive and move actively for at least five days.

Normal lymph glands are readily obtained from the omentum in cases of gastrectomy for peptic ulcer.

## Effect of Acetoacetate on the Succinic Acid Oxidase System

The effect of alloxan, a well-known diabetogenic substance, on blood glutathione[1] and enzymes[2] indicates that it is possible that its diabetogenic action may be through its effect on enzyme systems. Lazarow[3] has discussed this possibility at length, and has also suggested that acetoacetic acid or a related compound may have a direct toxic action on the enzymes in the beta-cells of the pancreas and may thereby have an alloxan-like action. The recent findings reported from this laboratory that blood glutathione is lowered by acetoacetate injection may serve as an additional indication of acetoacetate acting adversely on sulphydryl enzymes. In a preliminary observation on a simple —SH enzyme papain[5], it was noticed that acetoacetate could completely inactivate the enzyme at a concentration of 16 m*M*.

We have now investigated the effect of acetoacetate on the succinic oxidase system. This system was chosen for investigation because: (i) it is the simplest —SH enzyme known to be present in almost all tissues, including the beta-cells of the pancreas; and (ii) it is an important member of Krebs's tricarboxylic acid cycle.

Succinic oxidase activity was estimated in a Warburg apparatus by the method of Schneider and Potter[6], using rat liver homogenate as the source of the enzyme, the substrate being at a concentration of 0·03 *M*. When both the enzyme and acetoacetate were added simultaneously to other reactants, it was observed that acetoacetate effectively inhibits the enzyme only in concentrations comparable to that of the substrate. Thus acetoacetate in a concentration of 0·04 *M* was found to inhibit the activity to the extent of 79·2 per cent. Only 18 per cent inhibition was noted in presence of 0·0024 *M* acetoacetate. The effect of intermediate concentrations of acetoacetate showed that its action is progressive, the inhibitory effect depending on the time of incubation as well as on the concentration of the inhibitor.

When the tissue homogenate is subjected to preliminary incubation in the side-arm with acetoacetate prior to its addition to other reactants in the main compartments of the Warburg flask, extremely small amounts of the inhibitor are found to be effective. Thus $2 \times 10^{-4}$ *M* concentration of acetoacetate completely inhibited the enzyme activity. The least concentration of acetoacetate to obtain observable inhibition (8 per cent) is $0 \cdot 4 \times 10^{-4}$ *M*.

*Protection of the enzyme with glutathione.* It was found that glutathione protected the enzyme only when it was present prior to the addition of acetoacetate to the enzyme. When added after the action of the inhibitor on the enzyme was complete, it usually failed to reverse the inhibition. Protection to the extent of only 80 per cent activity was afforded by $2 \cdot 6 \times 10^{-3}$ *M* glutathione. It will thus be clear that the enzyme cannot be completely protected even when the concentration of glutathione is more than several times the molecular equivalent of acetoacetate; $3 \cdot 2 \times 10^{-4}$ *M* glutathione gives 12 per cent protection to the activity of the enzyme. All experiments on protection with glutathione were conducted in presence of that concentration of acetoacetate which completely inhibits the enzyme.

Probably the carbonyl function of the acetoacetate molecule reacts with the active sulphydryl group of the enzyme, thus making it impossible for the substrate succinate to form the enzyme-substrate complex.

The results presented here indicate that an accumulation of over-production of acetoacetate may upset the normal carbohydrate metabolism. It may interfere either directly, inhibiting the —SH enzymes, or by affecting the glutathione content of the cells. Glutathione, the naturally occurring tripeptide, serves to protect the —SH enzymes of the cells and thus maintains them in an active state. Several enzymes in the beta-cells of the pancreas may also require active sulphydryl groups[6]. If these are involved in insulin synthesis, then acetoacetate at high concentration may inhibit the production of insulin also. Certain observations by Nath and Brahmachari[7] indicate that some such disturbances can be induced by acetoacetate in the production of insulin in the living system.

A detailed report regarding these investigations will be published elsewhere. We are grateful to the Indian Council of Medical Research for the award of a research grant to one of us (V. G. H.).

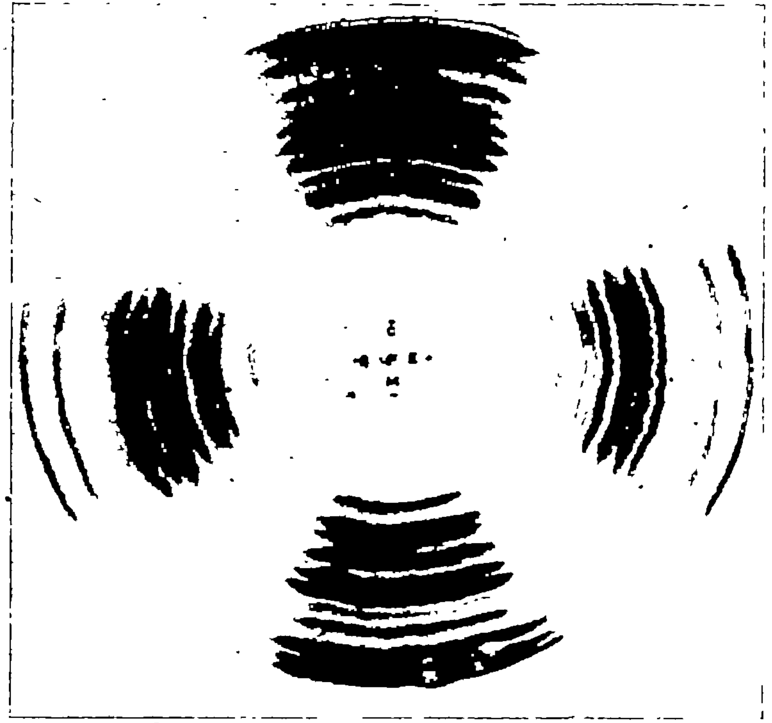
## Filter-Paper Disk Chromatography

In a recent communication by Proom and Woiwod[1] commenting on circular paper chromatography, they state: "although the method is admirable for the separation of two or three substances, it is not a satisfactory substitute for large-scale paper chromatography in the separation of more complex mixtures such as protein hydrolysates".

A brief description of this technique was communicated on October 4, 1951, and first published in the November 1951 issue of *Current Science*[2]. A modification of this technique for the separation and identification of amino-acids was communicated to *Nature* on November 19, 1951, and published in *Nature* of May 31, 1952[3]. The paper by Proom and Woiwod[4] was published in the October 1951 issue of the *Journal of General Microbiology* and was received in India early in 1952. We could not, therefore, notice this paper before we communicated ours for publication. It is obvious that our technique was developed independently of Proom and Woiwod's report.



Chromatogram showing the separation of amino-acids present in the hydrolysates of casein (*C*), gelatin (*G*) and edestin (*E*). *M*, mixture of known amino-acids. Whatman No. 1 filter paper (18¼ in. × 22¼ in.), *n*-butanol – acetic acid – water (40 : 10 : 50), solvent used. 20 µl. of hydrolysate (12·5 per cent nitrogen) spotted

Our experience with this technique for the past one and a half years and the results so far obtained by the application of this technique to the separation of amino-acids in protein hydrolysates show without any doubt that it is well suited to the separation, identification and even quantitative estimation of most of the amino-acids present in protein hydrolysates, as is evident from the papers published by us[5]. The failure to achieve separation of a large number of amino-acids present in protein hydrolysates by this technique as reported by Proom and Woiwod is probably due to the use of solvents such as *m*-cresol and small-size filter papers (12·5 cm. diameter) in the investigations reported in their paper. We have been able to separate all the amino-acids present in protein hydrolysates by using *n*-butanol – acetic acid – water (40 : 10 : 50), pyridine – water (80 : 20); and pyridine – amyl acetate – water as solvent mixtures. The use of large-size (35 cm. diameter) filter papers is found to be more advantageous for better resolution. The accompanying photograph is of a typical chromatogram showing the separation of amino-acids present in casein, gelatin and edestin hydrolysates into as many as eleven distinct bands on a large sheet of filter paper (22¼ in. × 18¼ in.).

The wide application of this technique to the investigation of many problems in this laboratory indicates its value in chromatographic analysis.

## Use of Unneutralized Hydrolysates in Paper Chromatography of Sugars

IN preparing hydrolysates of polysaccharides for paper chromatography, it has always been considered necessary to neutralize the sulphuric acid with barium carbonate before applying the solution to the paper, as the acid causes disturbing stains. Indeed, when using an ammoniacal silver spray, white stains appear at the place where the spots of glucose and galactose should be; but the flow of the sugars does not seem to be disturbed.

It occurred to me that an acid spray as, for example, aniline phthalate or phosphate, would not be impeded by the acid of the hydrolysate. In order to examine this, I carried out some experiments with (1) a simple solution of some sugars in *N* sulphuric acid; (2) a polysaccharide hydrolysate.

From both solutions chromatograms were made without previous neutralization, using benzene–butanol–pyridine–water (1–5–3–3) as a solvent and aniline phosphate as a spray. All sugars and uronic acid showed up clearly at their usual places, whereas no stains of the acid could be detected.

Quantitative determinations were also made on both solutions before and after neutralization, using rhamnose as a reference sugar. The sugar zones were eluted under reflux and the sugars estimated colorimetrically[1].

The results were as follows:

SOLUTION OF SUGARS IN *N* SULPHURIC ACID

| | mgm. added | mgm. found: in acid solution | mgm. found: in neutral solution |
|---|---|---|---|
| Galactose | 10 | 10·0 | 10·4 |
| Glucose | 10 | 9·6 | 9·4 |
| Arabinose | 20 | 20·2 | 19 8 |
| Xylose | 40 | 39·8 | 39·0 |

POLYSACCHARIDE HYDROLYSATE

| | Acid hydrolysate | Neutralized hydrolysate |
|---|---|---|
| Galacturonic acid | 2·6 per cent | 2·8 per cent |
| Galactose | 1·2 ,, | 1 5 ,, |
| Glucose | 3·8 ,, | 3·6 ,, |
| Arabinose | 8·7 ,, | 8·6 ,, |
| Xylose | 67·1 ,, | 65·6 ,, |

The results obtained show clearly that it is not necessary to neutralize the hydrolysates of polysaccharides before applying them to paper chromatograms, provided an aniline phosphate or phthalate spray is used.

## Detection of some Precursors of Adrenaline by Paper Chromatography

DURING studies on the biosynthesis of adrenaline, both *para*- and *meta*-hydroxyphenylethanolamine have been found to form noradrenaline following ultra-violet irradiation in the presence of air[1]. Whereas the *para* compound has been identified in *Octopus vulgaris*[2], the *meta* compound has not hitherto been found occurring naturally. Their detection in biological materials is a major problem. With the aid of paper chromatography, using a solvent of butanol (4 vol.), glacial acetic acid (1 vol.) and water (5 vol.), we have found that the *meta* compound exhibits an intense violet fluorescence under ultra-violet light when the developing agent is a mixture of 9 vol. of a solution of either potassium ferricyanide or dichromate (0·66 per cent) and 1 vol. of formaldehyde (40 per cent), followed by exposure to heat (100° C.) for 5 min. As little as 0·5 μgm. ($R_F$ value 0·56) can be identified by this test. Development with the *p*-nitraniline reagent[3] results in a dark red spot (similar to that produced with the *para* compound), but this test is only sensitive to 5 μgm.

Using the mixture of ferricyanide (but not dichromate) and formaldehyde as developer, followed by heating at 100° C., we have now found that noradrenaline ($R_F$ value 0·28) exhibits a turquoise fluorescence in ultra-violet light, and as little as 0·2 μgm. can easily be detected on chromatography paper. Under similar conditions, adrenaline ($R_F$ value 0·36) shows a yellow-green fluorescence if a minimum of 0·4 μgm. is present. Adrenaline in simple alkaline solution develops a transient green fluorescence, and Gaddum and Schild[4] in 1934 directed attention to the specificity of this reaction at low concentrations. Many substances chemically related to adrenaline (for example, noradrenaline and dihydroxyphenylalanine) produce the same green fluorescence only in much stronger concentrations. For example, West[5] found that noradrenaline is about thirty-three times less active than adrenaline in this test.

Using chromatography and the new developer (ferricyanide and formaldehyde mixture), noradrenaline is twice as active as adrenaline, so that very small amounts of noradrenaline can be detected in the presence of much larger quantities of adrenaline. Under similar conditions, both hydroxytyramine ($R_F$ value 0·39) and dihydroxyphenylalanine ($R_F$ value 0·19) show a yellow fluorescence if a minimum of 1·0 μgm. is present.

## Occurrence of Hydroxylamine in Lake Waters as an Intermediate in Bacterial Reduction of Nitrate

THE occurrence of hydroxylamine as an intermediate of the enzymatic reduction $NO_3^- \rightarrow NH$ or oxidation $NH_3 \rightarrow NO_2^-$ has recently interested many biochemists[1]. Thus certain authors have been able to confirm the formation of this compound in the process of the oxidation or reduction of nitrogen compounds[2,3].

The following observations (see table) show that hydroxylamine occurs in the water of Kizaki-ko, a mountain lake in Central Japan, mesotrophic in nature and with a maximum depth of 29·5 m. In this lake, in the middle of autumn, there appears every year a very pronounced stratification of inorganic nitrogen compounds. At the beginning of summer, the nitrate increases with increasing depth and as the period of stagnation proceeds, the oxygen content decreases in the bottom layers. In these layers, the activities of nitrate-reducing bacteria

* These samples were collected by a special sampler devised in our laboratory.

become vigorous, and stratification of nitrogen compounds results. A regular decrease in nitrate from the layer at 26 m. down to the bottom corresponds to a regular increase in nitrite and hydroxylamine. Thus it seems that these two compounds are produced by the bacterial reduction of nitrate, favoured by an environment poor in oxygen.

Determination of hydroxylamine was carried out using the modification proposed by R. Novak and P. W. Wilson[2]. Details of the present investigation will be published elsewhere.

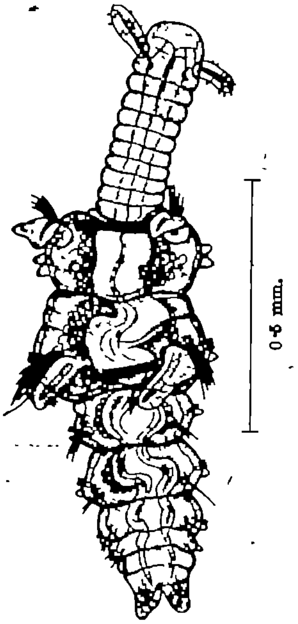
## Asexual Reproduction in *Pygospio elegans* Claparède (*Polychaeta sedentaria*)

DURING the course of an ecological investigation of the polychaete annelid *Pygospio elegans* Clap., a remarkable mode of asexual reproduction was noticed. The species were collected at the small island of Vorsø in the Horsensfjord (East Jutland, Denmark) and the phenomenon was first observed in April 1949.

*Pygospio* lives in quite shallow water, where its thin tubes are found vertically in the sandy bottom. Normally, it has sexual reproduction with pelagic or non-pelagic larvae according to different quantities of nurse eggs[1]. It has now been found able to reproduce asexually. The bodies of the adults, both males and females, divide into pieces consisting of varying numbers of segments, generally about three or four, sometimes up to seven; several times fragments consisting of one segment only have been observed. Fission takes place in any part of the body. When just separated, the single fragment looks as if it had been cut off with a knife. After the division, the series of fragments will stay in the tube until each has developed into a new animal. The fragments are very active and move up and down in the tube, which they never leave, however, until regeneration is completed. Every single fragment is able to form a new individual exclusively from its own tissue. The rate of regeneration is very high, and at 20° C. the regeneration of a new animal was completed in eight days; then the asexually formed individual will start a new division process. The original fragment is so closely incorporated into the new animal that no difference between old and new segments can be seen. So far as I know, this is the first case of asexual reproduction described in a species of the family Spionidae.

At Vorsø, asexual development can be found at any time of the year; as a rule only a few adult individuals are seen dividing. In the early spring, however, just after normal sexual reproduction has ceased (at Vorsø sexual breeding occurs in winter), asexual reproduction rises to a maximum.

In 1949, the asexual period was rather short (from the end of April to the beginning of May) and nearly all adult animals examined were dividing.



In 1950 the period was much longer (from the middle of March to the end of April), and only a minor part of the adult population was dividing.

Preliminary experimental work has shown that temperature significantly influences the asexual reproduction. Outside the natural period of asexual reproduction, it is possible to induce fission and regeneration by exposing adults to temperatures of 4–5° C. Weather observations from the spring periods of 1949 and 1950 seem to confirm the importance of temperature. In 1949 the break of the frost occurred very suddenly and in a short time the average temperature of the day period increased to about 10° C., while in 1950, the rise of temperature occurred very slowly; this may explain the differences in the asexual breeding in 1949 and 1950.

The mode of reproduction described above, when occurring generally, may have interesting ecological effects. Thus if the organism is decimated by a severe winter, asexual breeding will make possible a rapid recovery of numbers.

Further investigations of *Pygospio elegans* have been made at other Danish localities, especially the Isefjord (Zealand), and at various seasons; but so far asexual reproduction has only been observed at Vorsø in the Horsensfjord.

The accompanying drawing shows two segments of a mature male *Pygospio* with regenerated head and tail part, the head being the younger section. The investigations are being continued, and later on a more detailed report will be published elsewhere.

## A Gene for Photoperiod Sensitivity in Rice linked with Apiculus Colour

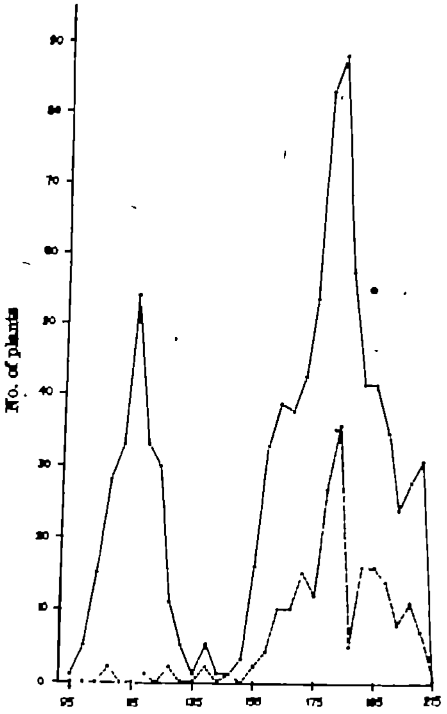
LACK of appreciation of the importance of length of day in determining the onset of flowering has vitiated much of the earlier work on the inheritance of age in rice. No genetic analysis of photoperiod response in this plant has yet been published. In the past two years, I have investigated the inheritance of photoperiod sensitivity. The Ceylon pure line, Vellai Ilankalayan 28061, which blooms approximately one hundred days after sowing, and is relatively insensitive to the photoperiod, was crossed with the Burma lines, *MLYC* 401 and *HMC* 12, which have, in the short days of the North-East Monsoon season, about the same sowing-to-flowering interval as the former, but are, to a high degree, sensitive to the photoperiod. The annual variation in length of day in Ceylon (lat. 5°-55′–9° 50′ N.) is less than one hour, but this variation exerts a profound influence on the flowering of the sensitive varieties. The growing of segregating progenies in the long days of the South-West Monsoon season makes the separation of sensitive and day-neutral forms possible. The parents and the $F_1$ and $F_2$ generations were sown at the same time, namely, May 1, 1952, at the Rice Research Station, Batalagoda. The mean intervals from sowing to panicle emergence for the parents and the $F_1$ are shown in Table 1.

Table 1

| Generation | Mean No. of days from sowing to panicle emergence |
|---|---|
| Parents { Vellai Ilankalayan 28061 | 105 ± 2·65 |
| Parents { *MLYC* 401 | 164 ± 2·29 |
| $F_1$ | 169 ± 1·87 |

Sensitivity shows complete dominance in the $F_1$ generation. The apparent heterosis is not significant. The segregation of the $F_2$ is illustrated in the accompanying graph, and is seen to be bimodal. The first mode corresponds to the emergence of the day-neutral segregates, and the second to the sensitive segregates. The numbers in the two classes fit well, as is shown in Table 2, into a monohybrid ratio, and indicate the determination of sensitivity by a single pair of genes to which I propose assigning the symbols, *Se se*.

The analysis of the $F_2$ segregation revealed the linkage of sensitivity with apiculus colour, *Ap ap*. The genes enter the cross in the repulsion phase, *Se ap/se Ap*; Vellai Ilankalayan 28061 is homozygous for the dominant purple apiculus, and *MLYC* 401 for the recessive white apiculus. The distribution of



Segregation in $F_2$ for sensitivity and apiculus colour. ——, total plants; – – – –, plants with white apiculus

Table 2

| | No. of plants in $F_2$ segregation | | |
|---|---|---|---|
| | Sensitive | Day-neutral | Total |
| Observed | 666 | 216 | 882 |
| Expected on 3 : 1 ratio | 661·5 | 220·5 | 882 |

$\chi^2 = 0·122$; $P = 0·95 - 0·50$.

plants with a white apiculus is illustrated in the graph. The observed numbers of plants in the $F_2$ classes and the expectations based on independence are given in Table 3.

Table 3

| | No of plants in $F_2$ segregation | | | | |
|---|---|---|---|---|---|
| | Sensitive, apiculus purple | Sensitive, apiculus white | Day-neutral, apiculus purple | Day-neutral, apiculus white | Total |
| Observed | 470 | 196 | 211 | 5 | 882 |
| Expected on 9 3·3:1 ratio | 496·1 | 165·4 | 165·4 | 55·1 | 882 |

$\chi^2 = 197·276$, $P < 0·01$.

The cross-over value for the two pairs of genes estimated from the $F_2$ is 16·3 ± 3·26 per cent.

Photoperiod sensitivity showed similar $F_2$ segregation and linkage with apiculus colour in crosses with *HMC* 12.

A full account of this work will be published elsewhere.

## Contamination of *Azotobacter chroococcum* by Gram-negative Bacterial Rods

IN a recent investigation, it proved virtually impossible to obtain a pure culture of *Azotobacter chroococcum*. After initial isolation from soil in flasks containing 2 per cent mannitol and 0·02 per cent sodium phosphate in tap water, progressive subcultures were made on solid nitrogen-free medium containing washed agar and the same percentages of mannitol and phosphate in distilled water—a recognized procedure for purifying *Azotobacter*[1]. Characteristic colonies of *Azotobacter* were obtained in about a month, and stained smear preparations of these colonies revealed only the characteristic large cells of the organism. If, however, colonies were inoculated into peptone water (in which *Azotobacter* will not grow[2]) a faint haze due to growth of small Gram-negative rods appeared after 24–48 hr. incubation at 22° C. A more abundant growth of these rods was obtained in 24 hr. on nutrient agar containing 0·1 per cent whole milk, whereas on this medium the growth of *Azotobacter* was very poor after three to four days. Subculture of *Azotobacter* on solid nitrogen-free medium (above) was therefore extended up to periods of four months, and 0·1 per cent sodium silicate, 0·002 per cent iron ($FeCl_3$) and boron, 0·00004 per cent sodium molybdate, soil extract and hay-infusion were incorporated in some cultures to heighten the resistance of *Azotobacter*. In practically all cases, however, the contamination persisted. On the one or two occasions on which it appeared to be absent, growth of *Azotobacter* was very poor, marked by absence of the characteristic mucilage, and ceased within seven to fourteen days; nor could it be restored by incorporation of any of the above substances. Fourteen strains of contaminants were isolated the cultural characters of which proved conclusively they were not pleomorphic forms of *Azotobacter*, the majority being strains of *Pseudomonas* (fluorescent and non-fluorescent) with one or two species of *Achromobacter*. In the absence of *Azotobacter*, they grow well up to four weeks in flasks of the above liquid mannitol medium, reducing its reaction to a pH of 4·0 in a fortnight although growth was still vigorous. Their source of nitrogen in such cultures is obscure. They grew in liquid media, distilled water with 1 per cent glucose and ammonia (0·1 per cent $(NH_4)_2HPO_4$) as the sole source of nitrogen; but only feebly in 1 per cent glucose only. Incorporation of whole killed cultures, extracts or filtrates of cultures improved growth of *Azotobacter* on solid nitrogen-free media and improved its mucilage production.

Large numbers of contaminants depressed the growth of *Azotobacter* in nitrogen-free liquid media when they were grown in association. Fluorescent strains of *Pseudomonas* destroyed the *Azotobacter* cells.

All the contaminants were freely ingested by soil ciliate protozoa which multiplied in their presence. Fluorescent *Pseudomonas* inhibited growth of *Colpoda* sp. but not, for example, *Urostyla grandis*, which fed upon it.

*Azotobacter* is reported to be accompanied in Nature by a small Gram-negative rod *Radiobacter*[3] the relationships of which are ill-defined. The present findings suggest that association with common Gram-negative rods may persist unsuspected in laboratory cultures regarded as pure.

These observations were carried out when I was serving as senior bacteriologist in the National Agricultural Advisory Service of the Ministry of Agriculture, and thanks are due to C. D. Oxley, provincial bacteriologist, and F. W. Catton, assistant bacteriologist, for material advice and assistance.

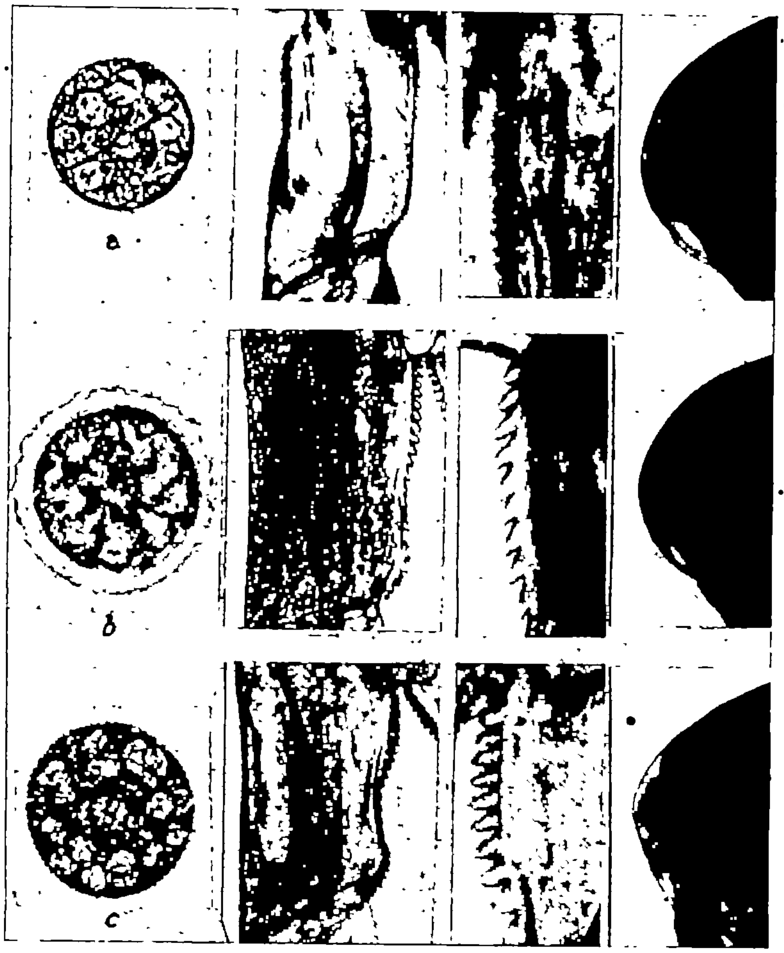
## *Calanus finmarchicus* and Related Forms

THE copepod *Calanus finmarchicus* has been more thoroughly investigated than any other marine plankton organism. Some systematists have recognized in the material from European[1] and eastern American waters[2] two distinct species, *C. finmarchicus* and *C. helgolandicus*; but the distinguishing characters given have been too uncertain to receive universal acceptance[3]. In consequence, it has been assumed in most studies of the copepod—its population changes, physiology, behaviour, etc.—that the material used consists of a single species. Recently[4], it was pointed out that two forms, corresponding to the two species, could be readily distinguished in the female and copepodite stage V by the structure of the basipod of the fifth swimming feet, though their status, whether species or sub-species, remained



Typical eggs, the basipod segment of the left fifth legs, the proximal teeth of the basipod of the right fifth legs and the foreheads of females of (*a*) *Calanus finmarchicus*, (*b*) the *Calanus* from Tromsø, and (*c*) *C. helgolandicus*

undecided. It has also been shown[5] that the eggs of *helgolandicus* are bigger (165–180 μ in diameter) than those of *finmarchicus* (135–155 μ). Following upon the more definite means of identification, it is becoming recognized that in future research the two forms should be distinguished[6].

In the early spring of 1952, in Tromsø Sound, northern Norway, the majority of female *Calanus* caught were *finmarchicus*; no *helgolandicus* was found. About 10 per cent, however, laid eggs of the same size as *helgolandicus*; but these, shortly after laying and before the first cleavage, produced a rugose membrane with a clear space between it and the egg, varying in width (see photographs). These eggs were viable and hatched into nauplii slightly larger than those of the normal *finmarchicus*.

Out of well over a thousand females observed laying eggs in the laboratory at Millport, two have produced similar eggs with membranes; but in neither case were the eggs healthy and unfortunately neither of the females was examined in detail.

Some of the Tromsø females which laid these eggs were later examined and compared with typical examples of *finmarchicus* and *helgolandicus* (see photographs). In *finmarchicus* the teeth of the basipod of the fifth legs are arranged along the edge of the segment and are numerous and small; the forehead is evenly round. In *helgolandicus* the tooth line curves round to the posterior side of the segment, giving a marked concave appearance to the inner margin of the segment, the teeth being fewer and larger than in *finmarchicus*; the forehead is more or less pointed. The *Calanus* from Tromsø show mixed and intermediate features of the two forms so far recognized. The tooth line is curved, but the curvature is small and more like *finmarchicus* than *helgolandicus* in this respect; but the teeth are similar to those of the latter in number and size; the forehead resembles *finmarchicus* in being evenly round.

Morphologically, the Tromsø *Calanus* are sufficiently distinctive to constitute a third form. Two possible interpretations immediately present themselves. The first, and the more likely, is that they have the same status as *C. finmarchicus* and *C. helgolandicus*, be this species or sub-species. The second is that they have arisen through interbreeding of the two other forms. This seems less likely, for in the areas where these two forms are commonly found together, the Tromsø form is extremely rare or absent, whereas it formed up to 10 per cent of the catch in the Arctic where *C. finmarchicus* predominates.

## Life-history of *Fasciola gigantica* Cobbold 1856

FOLLOWING the elucidation by Thomas[1] of the life-history of *Fasciola hepatica*, numerous investigations have established the important aspects of the relationship between the fluke and its snail hosts. By contrast, knowledge of the related *F. gigantica* is extremely limited, and in many parts of the world even the identity of its vectors has not been confirmed.

During the course of a recent field survey which was initiated by the Food and Agriculture Organization of the United Nations as part of a programme of liver-fluke control in Pakistan, the Veterinary Laboratory of the Ministry of Agriculture at Weybridge was used as a central laboratory for experimental work for which facilities did not exist in Pakistan. At Weybridge, the use of laboratory techniques which had been developed for work on *F. hepatica* and its host *Lymnaea truncatula* made it possible readily to observe the development of *F. gigantica* under controlled conditions both in molluscs and in mammalian hosts.

Snails which had been collected near Rawalpindi in Pakistan were kept under observation in shallow earthenware dishes of water at the Central Laboratory of the Animal Husbandry Department, Peshawar. Egg-laying commenced within three weeks. On February 2, 1952, two egg masses were sent by air to England. Snails from these egg-masses were exposed to infection with the miracidia of *Fasciola gigantica* (also of Pakistan origin) on March 24. Development of the parasite proceeded to completion at laboratory temperatures, emergence of mature cercariae being first observed on June 10, 78 days after infection.

Starting on July 3, a lamb (aged fifteen weeks) was given a total of two hundred cercariae over a period of nine days. On October 21 (110 days later), eggs of *Fasciola gigantica* were recovered from the fæces. An identical period of time proved necessary for the full development of the parasite in a calf. This may be compared with an average of about seventy days necessary for the development of *Fasciola hepatica* both in sheep and in calves.

The snails used in these observations have been identified for us by Mr. G. L. Wilkins, of the British Museum (Natural History), as *Lymnaea rufescens* Gray (a species considered by Hubendick[2] to be merely a race of the well-known *L. auricularia*). *L. auricularia rufescens* (Hubendick[2]), showing great variation in shell morphology, occurs widely throughout east and west Pakistan, where field observation suggests that it is the principal vector of *Fasciola gigantica*. Most shells are similar to the forms of *L. acuminata* described by Annandale and Rao[3]. The snails are often found as true aquatics in large bodies of permanent water, the frequent connexion with deep pools possibly having an association with a negatively phototropic reaction which we have observed in the miracidia of *F. gigantica*. This response, although not noted by Alicata[4] in Hawaii, is, under our laboratory conditions, most marked and in direct contrast to the strong positive phototropism of the miracidia of *Fasciola hepatica* which in Pakistan, as in Europe, parasitizes the amphibious *L. truncatula*.

At Weybridge *L. auricularia rufescens* has readily accommodated itself to a restricted habitat. Management very similar to that recommended by Taylor and Mozley[5] for the culture of *L. truncatula* has proved satisfactory, although it has been found necessary to maintain a depth of one to two inches of water in the culture dishes.

Further observations on the life-history are being made and will be recorded at a later date. In particular, we are interested in the possibility of the British *L. auricularia* (L.) proving susceptible to infection with *Fasciola gigantica*.

## A Method for the Bulk Growth of a Parasitic Protozoan

THE biochemical study of protozoan species has been hampered by the difficulty of obtaining large quantities of clean, dried organisms to serve as starting material for investigation. The solution of the problem of bulk growth of the protozoan cattle parasite, *Trichomonas foetus*[1], made possible an immunochemical study of the organism[2].

*Trichomonas vaginalis*, a protozoan parasite of man, presents a similar problem. Strains isolated in a bacteria-free state by the use of antibiotics[3] can be grown in culture media in current use, but in the best reported conditions only about $2 \times 10^6$ organisms per ml. are obtained after three to four days in 5 or 10 ml. quantities of medium. For the practical harvesting of dried organisms, litre quantities of culture containing $4–5 \times 10^6$ organisms per ml. are desirable[2]. A further drawback of most published media for *T. vaginalis* is the inclusion of particulate matter (agar or rice starch), which makes it difficult or impossible to collect the organisms in the pure state.

The starting point for the current investigation was the agar-free modification by McEntegart[4] of the C.P.L.M. medium of Johnson and Trussell[5]. It was determined that a Liverpool strain of *T. vaginalis*, which had become adapted to McEntegart's medium, would grow in it at $1–1{\cdot}5 \times 10^6$ per ml. when subcultured at 48-hr. intervals. Stepwise modification of this medium led to the following formula for a medium in which this Liverpool strain will attain a growth-level of $4–6 \times 10^6$ per ml. within 24 hr. and which will support such growth in bulk volumes.

| | |
|---|---|
| Ascorbic acid | 3·7 gm. |
| L-Cysteine hydrochloride | 2·5 gm. |
| Proteolysed liver B.P.C. (ref. 6) | 1·0 gm. |
| Glucose | 10·0 gm. |
| Distilled water | 1,200·0 ml. |
| Bovine serum | 160·0 ml. |
| Douglas's digest broth, double strength (ref. 7) | 1,000·0 ml. |
| *M* Sodium hydroxide to *p*H 5·8–6·0 | |

The medium is sterilized by passing through a Seitz filter and should be used within fourteen days. For tube-growth, 10-ml. amounts are inoculated with 0·5 ml. of an actively growing culture and incubated at 36–37° C. Sub-culturing is done daily.

Bulk growth is carried out in 80-oz., narrow-necked, round bottles, using 2 litres of medium per bottle. The necessary inoculum for each bottle is obtained by successive 24-hr. subcultures in (*a*) a tube and (*b*) 100 ml. of medium in an 8-oz. flat medicine bottle. The medicine bottle receives 5 ml. inoculum from the tube and contributes 100 ml. inoculum to the bulk bottle. All bottles are warmed in the incubator for 24 hr. prior to inoculation.

The organisms from the bulk cultures are collected and thrice washed by centrifugation and re-suspension in saline. After the final centrifugation they are suspended in a small quantity of distilled water, frozen and dried from the frozen state. The yield is 1·1–1·5 gm. dried organisms per bottle.

The suitability of this culture medium for *T. vaginalis* has been further demonstrated by the successful isolation of two new bacteria-free strains from clinical material, using 1,000 units penicillin and 500 units streptomycin per ml. Initial growth was slow; but after several passages the strains (Whitechapel 1 and 2) adapted themselves to the medium and are now growing at 4–5 × $10^8$ per ml. A single attempt at bulk growth with Whitechapel 1 yielded 1 17 gm. from one bottle.

Of special interest is the observation that proteolysed liver B.P.C.[6] can replace the 'Difco' liver infusion called for in the C.P.L.M. medium[4,5]. Attempts to grow the organisms without liver (or a substitute infusion of human red blood cells) were unsuccessful. Proteolysed liver B.P.C. is a completely soluble, inexpensive material and may prove useful as a substitute for liver infusion or as a growth-promoting inclusion in media for the culture of other micro-organisms.

A fuller account of this investigation will be reported elsewhere. I am indebted to Dr. M. G. McEntegart, Liverpool City Bacteriological Laboratory, for his original culture and medium; to Dr. Claude Nicol, Whitechapel Clinic, for clinical specimens; to Messrs. Paines and Byrne, Ltd., Greenford, Middlesex, for generous quantities of 'Pabyrn' brand proteolysed liver B.P.C.; and to Mr. C. D. Bevis, Lister Institute, for technical assistance.

## Excess of Molybdenum in Herbage as a Possible Contributory Factor in Equine Osteodystrophia

DEFECTS in nutrition which predispose to osteodystrophic conditions in the horse include a dietary deficiency of phosphorus[1] or disturbance in the vitamin D – calcium – phosphorus relationship. With regard to the influence of trace minerals, Davis[2] found that the presence of small amounts of molybdenum, ranging from 2 to 25 p.p.m. in young growing herbage, was associated with defective bone metabolism in herbivora, consequent on the effects of molybdenum on the utilization of both phosphorus and copper. More recently, Arrington and Davis[3] in limited phosphorus metabolism studies with rabbits reported that molybdenum decreased phosphorus absorption while at the same time increasing the excretion of phosphorus.

On some twelve farms where we have investigated the occurrence of clinical rachitis in one or more of the foals or yearlings, we have found that the molybdenum content of the grazing herbage has been within the range 5–25 p.p.m. The soils on these farms are mainly derived from limestone, being of a similar nature where soil type, manurial treatment and management are concerned to those on which molybdenum-conditioned copper deficiency has previously been identified by us[4]. In addition, readily available molybdenum determinations on these soils have shown values in the region where excess levels of molybdenum in herbage are likely to occur. While it has been impossible so far to ascertain to what extent molybdenum may be an etiological factor, we suggest that a foal running with its dam on such pastures would receive an excessive intake of molybdenum from the mare's milk and from the herbage. In view of the work referred to above, such a foal would be more susceptible to osteodystrophic conditions as a result of the influence of molybdenum on the metabolism of both phosphorus and copper. Consequently the extent to which molybdenum in moderate excess in pasture may predispose to the development of poor bone in the young horse and afterwards to poor performance in later life is raised.

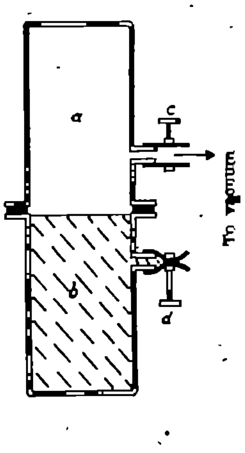
## Apparatus for Infiltration of Liquids into Leaves

VACUUM infiltration of liquids into leaves is a technique that has been used for many years. So far as I am aware, the usual procedure is to keep the leaf under liquid while reducing the pressure. Air bubbles then escape from the stomata, and any adhering when the lowest pressure has been attained are dislodged, often with difficulty, by shaking the container; for when the vacuum is afterwards released the adherence of these bubbles would spoil the efficiency of infiltration. The difficulty of bubble removal is greatly increased when a number of leaves are simultaneously infiltrated, so that it is desirable to use as few leaves as possible, or even to treat them singly. To overcome such difficulties it is best to reduce the pressure while the leaves are in air, releasing pressure only after putting the leaves under liquid. A convenient way of doing this is described below.

Two glass or metal containers of suitable strength, each with a side-arm and flange, are stood one upon the other, separated by a wet rubber washer. The leaves are held in chamber *a*, and the infiltrating fluid in *b*; *c* and *d* are clips on rubber pressure-tubing (glass stopcocks could be used) attached to the side-arms of the chambers. To evacuate the apparatus, *c* is opened, and when the desired degree of evacuation, read on a gauge, is reached, closed again. The whole arrangement is now inverted so that the infiltrating liquid runs on to the leaves. Then *d* is opened so



as to release the vacuum gently, and infiltration takes place.

Generally eight to ten leaves of *Atropa belladonna*, L., each 6·5 in. long and 3–3·5 in. at the widest, were simultaneously infiltrated. They were first rolled in a springy, spiral, piece of celluloid-like material 1–1·5 in. wide, and secured if necessary with a loose rubber band. The leaves so compacted were held in chamber *a* with their petioles at the bottom, by means of a suitable spring-clip.

The method gives complete infiltration with minimal reduction of pressure, and if a good rate of evacuation is obtainable the leaves need not be kept under reduced pressure, even with the relatively large chambers used, for more than a minute.

The quantity of infiltrating liquid required depends, of course, on the volume necessary to cover the leaves. For the number of leaves and dimensions given, nearly a litre was required, of which less than 15 ml. was retained by the leaves: this extravagance of the method is sometimes a drawback.

## Inheritance of Minor Colour Vision Variations

A considerable amount of attention has been given to the inheritance of major colour vision defects, namely, red-green blindness and anomalous colour vision[1–5], and the view most favoured at present is that there are two groups of totally sex-linked alleles with three members in each group (together with dominant normal genes) which determine major red and green defects. Walls has recently put forward the view that there might be a third locus, also with three alleles, and totally sex-linked, which determine blue vision defects[6].

Total sex-linkage of minor blue and yellow vision defects is not supported by the fact that these variations are as frequent in women as in men[4]. A study of forty pedigrees which reveal the inheritance of blue and yellow minor colour vision defects, collected in the course of testing 649 men and 546 women, strongly suggests that some of their more extreme forms are due to the action of partially sex-linked multiple allelomorphs. Partial sex-linkage is difficult to distinguish decisively from autosomal inheritance, but seems likely.

The minor defects of blue vision are defined as: (1) blue deviation, (2) blue weakness, and (3) blue-yellow weakness with darkened violet. The distinction between 'deviation' and 'weakness' has been explained fully elsewhere[4]. It is suggested that the appropriate genes might be called: $B$ (normal and most dominant), $b_1$, $b_2$ and $b_3$ (most recessive). The segregation of these genes is clearly apparent in the pedigrees, two of which suggest the dominance order and four suggest crossing-over between genes in the blue series.

The minor defects of yellow vision are defined as: (1) yellow deviation, (2) yellow weakness and (3) extreme yellow-blue weakness. The appropriate genes might be called: $Y$ (normal and most dominant), $y_1$, $y_2$ and $y_3$ (most recessive). Again, segregation can be seen clearly in the pedigrees, three of which suggest the dominance order and four indicate crossing-over between genes of the yellow series.

These facts seem to favour a four-receptor theory of colour vision.

In addition, five pedigrees show totally sex-linked forms of minor red and green deviation. These are very mild forms of red and green anomaly, two pedigrees for red, two for green and one for both together. Darkening of the red is shown in one pedigree. In order to explain these, it is necessary to assume a degree of heterozygous manifestation not much less than the defects of the hemizygotes themselves, though not always the same. This may be because the appropriate genes are the most dominant, next to the normal genes in the familiar protanope and deuteranope series, and have the greatest penetrance.

In many of the pedigrees, major red and green and minor blue and yellow variations occur together and may be traced out as segregating independently. Totally sex-linked major blue defects were not found in the population tested, but may occur.

Details of this investigation will be published fully elsewhere.

## Predacious Mosquito Larvæ

Apart from the obligatory cannibalism of the genus *Toxorhynchites* and the sub-genera *Mucidus* and *Lutzia*, cannibalism in other mosquito genera has been little studied. Graham[1] stated that the addition of 3 per cent common salt to the breeding water brought about cannibalism in *A. gambiæ*. This was not confirmed by subsequent work. It has, however, been observed in Mauritius that facultative cannibalism exists within the salt-water strain of *A. gambiæ*. Such a tendency has not been observed in the fresh-water strains of *A. gambiæ*.

Third- and fourth-stage larvæ can be seen to seize other larvæ, of all stages, by the abdomen and to commence to feed. This would appear to stimulate neighbouring larvæ, as within a few seconds numerous larvæ are feeding upon the hapless victim, whose vigorous struggles are usually in vain. The head capsule is all that remains, but larvæ can be seen attempting to extract the contents of the head capsule with their mouth brushes. Pupæ are immune from attack.

This tendency to cannibalism, in the presence of abundant larval food, brings about a considerable mortality in a laboratory culture. The breeding dishes are littered with head capsules each morning, the larval numbers being correspondingly reduced.

# FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

### Monday, June 29

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5 p.m.—Dr. Warren S. McCulloch: "Some New Techniques for the Electrophysiological Study of the Central Nervous System".*

### Tuesday, June 30

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE, PHILOSOPHY OF SCIENCE GROUP (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. Warren S. McCulloch: "Through the Den of the Metaphysician".

### Wednesday, July 1

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

INTERNATIONAL HAEMOPHILIA SOCIETY (at 94 Southwark Bridge Road, London, S.E.1), at 6.30 p.m.—Second Meeting of the London Group *

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SCIENTIFIC OFFICER, Grade I (with university degree of high standard in physics or electrical engineering or equivalent qualification, preferably electronic) in the High Speed Aerodynamics Laboratory, Salisbury, South Australia, to be responsible to a Senior Scientific Officer for the development of instruments for aerodynamic research and the adaptation of existing instruments for special purposes—The Senior Representative (A.P.2), Department of Defence Production and Supply, Australia House, Strand, London, W.C.2 (July 3).

ASSISTANT STATISTICIANS (with first- or second-class honours degree with statistics as a main subject, or a postgraduate university diploma or higher degree in statistics) in Government Departments—The Secretary, Civil Service Commission, Burlington Gardens, London, W.1, quoting 96/53 (July 4).

BIOCHEMIST (Basic Grade) (with B.Sc. degree, preferably with honours in biochemistry or chemistry, or equivalent qualification)—The House Governor, General Hospital, Birmingham 4 (July 4).

EXPERIMENTAL OFFICER at the Ministry of Supply Experimental Flying Establishment, Salisbury, for assessment and proving of aircraft camera installations for photographic survey and reconnaissance, and development of photographic methods applied to aircraft flight-testing—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F253/53A (July 4).

LECTURER (with a first- or second-class honours degree in physics or electrical engineering or equivalent qualifications) IN THE PHYSICS AND ELECTRICAL ENGINEERING DEPARTMENT—The Director of Studies, Royal Naval College, Greenwich, London, S.E.10 (July 4).

MAY AND BAKER RESEARCH FELLOWSHIP for research work on plant growth-regulating substances—The Registrar, Wye College, Ashford, Kent (July 4).

AGRICULTURAL ECONOMIST (at Bristol), and ASSISTANT AGRICULTURAL ECONOMISTS (4, 2 at Bristol and 2 at Newton Abbot)—The Registrar, The University, Bristol 8 (July 6).

ASSISTANT EXPERIMENTAL OFFICER AT THE POULTRY RESEARCH CENTRE, EDINBURGH, to assist in investigations involving histological, physiological and biochemical techniques—The Secretary, Agricultural Research Council, Cunard Building, 15 Regent Street, London, S.W.1 (July 6).

RESEARCH ENTOMOLOGIST (with good honours degree) for investigations on laboratory and field methods for the development and bioassay of insecticides—The Secretary, East Malling Research Station, Maidstone, Kent (July 7).

TUTORIAL STUDENTSHIP IN PHARMACOLOGY, and a TUTORIAL STUDENTSHIP IN ZOOLOGY (preferably of the vertebrates)—The Registrar, King's College, Strand, London, W.C.2 (July 7).

SENIOR RESEARCH FELLOWSHIP IN NATURAL PHILOSOPHY—The Secretary, The University, Aberdeen (July 8).

SYBIL MARY PILKINGTON FELLOWSHIP for research into diseases of the blood, with particular reference to the causation, treatment, and cure of leukaemia in man—The Registrar, The University, Manchester 13 (July 10).

ASSISTANT IN THE DEPARTMENT OF GEOGRAPHY—The Secretary, The University, Edinburgh (July 11).

ASSISTANT (Grade A) IN THE DEPARTMENT OF MATHEMATICS—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (July 11).

CHEMIST in a Ministry of Supply Establishment, Aldermaston, Berks, to develop and supervise a unit engaged on quantitative analysis of organic compounds by micro-combustion techniques—The Ministry of Labour and National Service, Technical and Scientific Register (K), Almack House, 26 King Street, London, S.W.1, quoting F.252/53A (July 11).

GRADUATE ASSISTANT IN PHYSICS (with university degree in physics, and special interest in electronics as applied to biological problems)—The Professor of Physiology, Department of Physiology, University Museum, Oxford (July 11).

STATISTICIAN (honours graduate, Scientific Officer grade)—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (July 13).

ASSISTANT LECTURER IN ECONOMIC STATISTICS in the Department of Political Economy—The Secretary, University College, Gower Street, London, W.C.1 (July 14).

ELECTRONIC ENGINEER in the Ministry of Supply, London headquarters, to supervise the development by industry of electroni navigation aids for Service use—The Ministry of Labour and Nationa Service, Technical and Scientific Register (K), Almack House, 26 Kin Street, London, S.W.1. quoting D.223/53A (July 14).

EXTENSION LECTURER IN SCIENCE (with special qualifications i natural science, preferably biology)—The Secretary, Universit Extension Lectures Committee, Rewley House, Wellington Square Oxford (July 15).

LECTURER IN EXPERIMENTAL PHYSICS—The Secretary of University Court, The University, Glasgow (July 15).

LECTURER IN MATHEMATICS at the Auckland University College New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 15)

LECTURER and an ASSISTANT LECTURER IN GEOGRAPHY—The Registrar, The University, Leeds 2 (July 15).

SENIOR EXPERIMENTAL OFFICER (with degree in a scientific or engineering subject or in mathematics, or a H.N.C., or a graduat membership of a professional institution) in the National Physica Laboratory, Teddington, to assist in co-ordinating the work of the workshops and design offices (which produce prototype precisio instruments and the apparatus needed for the laboratory's researc work)—The Civil Service Commission, Scientific Branch, Trinida House, Old Burlington Street, London, W.1, quoting S.4220/5 (July 15).

SENIOR LECTURER or LECTURER (Grade I) and a LECTURER (Grade II) IN CHEMISTRY, a LECTURER (Grade II) or ASSISTANT LECTURER IN ZOOLOGY (preferably with special interests in taxonomy and ecology), and a LECTURER (Grade I) IN MATHEMATICS, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council fo Higher Education in the Colonies, 1 Gordon Square, London, W.C. (July 21).

SENIOR RESEARCH OFFICER (Chemical Engineer) (with university honours degree in science, with chemistry as major subject, or i chemical engineering, and some industrial experience, preferably i research and development) at the Wool Textile Research Laboratory Geelong, Victoria—The Chief Scientific Liaison Officer, Australia Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 quoting 464/52 (July 25).

LECTURER IN BIOCHEMISTRY at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education i the Colonies, 1 Gordon Square, London, W.C.1 (July 31).

SENIOR LECTURER or LECTURER IN GEOLOGY at New South Wales University of Technology, Sydney, to teach geophysics and economic geology, and to undertake research in these fields—The Agent Genera for New South Wales, 56–57 Strand, London, W.C.2 (August 4).

CHAIR OF INORGANIC AND PHYSICAL CHEMISTRY in the University of Adelaide—The Secretary, Association of Universities of the Britis Commonwealth, 5 Gordon Square, London, W.C.1 (Adelaide, Augus 31).

SENIOR LECTURER (heavy current) IN THE DEPARTMENT OF ELECTRICAL ENGINEERING, University of Natal, Durban—The Secretary Association of Universities of the British Commonwealth, 5 Gordo Square, London, W.C.1 (August 31).

LECTURER IN BOTANY (special qualifications in Plant Physiolog would be an advantage) at New England University College (Universit of Sydney), Armidale, N.S.W.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C. (Armidale, September 1).

ASSISTANT, Grade B (with good honours degree in chemistry, and able to teach organic chemistry to final degree standard) FOR CHEMISTRY—The Clerk to the Governors, South-East Essex Technica College, Longbridge Road, Dagenham, Essex.

ASSISTANT, Grade B (with good degree in physics of a Britis university) IN PHYSICS—The Registrar, Medway Technical College Gardiner Street, Gillingham, Kent.

ASSISTANT (Assistant Experimental Officer grade) for general dutie IN THE PLANT PATHOLOGY SECTION—The Secretary, Scottish Horticultural Research Institute, Mylnefield, Invergowrie, Dundee.

ASSISTANT METEOROLOGIST in Trinidad—The Crown Agents fo the Colonies, 4 Millbank, London, S.W.1, quoting M3B/33626/NF.

ENGINEER, Grade I (Ref. 467) and ENGINEERS, Grade II and II (Ref. 468), for work on major calculations required by design office concerned with nuclear reactors and factories for producing fissil material—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting the appropriate Ref. No

EXPERIMENTAL OFFICERS and ASSISTANT EXPERIMENTAL OFFICER IN THE MINISTRY OF FUEL AND POWER at Sheffield and Kidderminste for underground gasification project exploring new technique to mak gas direct from the coal seam (Ref. F.256/53A); SCIENTIFIC OFFICER FOR SAFETY IN MINES RESEARCH ESTABLISHMENTS at Sheffield an Buxton (Ref. F.257/53A); ASSISTANTS (Scientific) at Sheffield an Buxton (Ref. F.258/53A); SCIENTIFIC OFFICERS IN THE CHIE SCIENTIST'S DIVISION, London (Ref. F.259/53A)—The Ministry Labour and National Service, Technical and Scientific Register (K Almack House, 26 King Street, London, S.W.1, quoting the appropriate Ref. No.

GEOLOGIST IN THE PUBLIC WORKS DEPARTMENT, Sudan—Th Sudan Agent in London, Sudan House, Cleveland Row, Londo S.W.1, quoting "Geologist 1810".

GRADUATE IN METALLURGY, CHEMISTRY or PHYSICS, to join group studying atomic movements in solids by means of radioacti tracers—The Secretary, The University, Leeds.

RESEARCH ENGINEER (good honours degree essential) for gener automobile engineering problems, for investigations concernin mechanical properties (in particular fatigue strength) of materials an components, and for investigations into loadings experienced b vehicle components on the road, riding characteristics of vehicle etc.—The Director, Motor Industry Research Association, Lindley Nuneaton.

SCIENTIFIC OFFICERS and SENIOR SCIENTIFIC OFFICERS for projec assessment groups at the Royal Aircraft Establishment, Farnborough and at Ministry of Supply London headquarters—The Ministry Labour and National Service, Technical and Scientific Register (K Almack House, 26 King Street, London, S.W.1, quoting A.161/53A.

# INDEX

## NAME INDEX

ABELSON, Dr. P. H.: Appointed director of the Geophysical Laboratory of the Carnegie Institution of Washington, 594; work of, 594
Abercrombie, Michael (edited by Johnson, M. L., and): New Biology, 13, review, 453
Abernethy, Frieda (Essig, Prof. E. O., and): The Aphid Genus *Periphyllus*, review by J. P. Doncaster, 765
Ábrahám, A.: Awarded a Kossuth Prize for 1953, 1010
Abraham, Dr. E. P., and others: Cephalosporin *N*, a New Type of Penicillin, 343
  Sulphur-containing Amino-acids of Nisin, 606
Adam, Jean, and others: Laws of Addition and Substitution in Atomic Reactions of Halogens, 704
Adams, Dr. G. F.: Some Social and Psychological Problems of Ageing, 422
Adams, J. B., and others: Effect of Magnet Inhomogeneities in the Strong-Focusing Synchrotron, 926
Adams, M. E.: Gelatine and Glue, 1101
Adamson, Dr. I. T. A. C.: Appointed lecturer in pure mathematics at Queen's University, Belfast, 1005
Addison, Dr. C. C., and Hodge, N.: The Trinitratouranyl Complex Ion 569
Addison, Dr. C. C., and Litherland, D.: Dynamic Potentials of Freshly Formed Liquid Surfaces, 393
Adlard, P. G.: Appointed assistant conservator of forests, Nyasaland, 111
Adrian, Dr. E. D.: *Obituary* of Prof. L. Lapicque, 153
  Flavour Assessment, 724
  Awarded the Albert Medal for 1953 of the Royal Society of Arts, 1005
Aeronautical Society, Royal: Election of Sir William Farren as president, 635
Aeronautical Society, Royal (Acoustics Group of the Physical Society and the): Discussion on Aeronautical Acoustics and Jet Noise in particular, 914
Africa South of the Sahara, Scientific Council for: Meeting to consider Sociological Research in Africa South of the Sahara, 246
  Symposium on the Hydrobiology and Inland Fisheries of Africa, 291
Africa (East) High Commission: Appointment of J. D. Randall as statistician, 201
  Appointment of R. L. Sykes as leather chemist, 201
  Appointment of D. McCallum as meteorologist, 333
  Appointment of A. Rogerson as scientific officer, 421
African (East) Fisheries Research Organization: Annual Report for 1951, 159
African (East) Tsetse and Trypanosomiasis Research and Reclamation Organization. Appointment of E. A. Lewis as director, 333
African (South) Association for the Advancement of Science: Fiftieth Anniversary, 963
African (West) Institute for Oil Palm Research: Transformed from the Oil Palm Research Institute, Benin, 595
Agricultural Advisory Service, National: Appointment of H. Trefor Jones as provincial director of the Yorks and Lancs Province, 377
Agricultural Botany, National Institute of: Appointment of A. Sandison as deputy director, 111
Agricultural Bureaux, Commonwealth: Election of Dr. E. Marsden as chairman, 246
Agricultural Department, Federation of Malaya. Appointment of Gunn Lay Teik as senior chemist, 678
Agricultural Department, Fiji: Appointment of V. E. Sills as biochemist, 958
Agricultural Engineers (British), Institution of: Scholarship, 333
  Election of David P. Ransome as president for 1953–54, 777
Agricultural History Society, British: First General Meeting, 420
  Inaugural Conference, 775
Agricultural Research Council: Careers in Agricultural Research—Training Grants, Studentships and Fellowships awarded by the, 330
  Re-appointment of Lord Rothschild as chairman, 1054
  Appointment of Prof. Stephen J. Watson as deputy chairman, 1054
Agricultural Society of New South Wales, Royal: Election of Prof. W. L. Waterhouse as an honorary life member, 20
Agriculture, Association of: Course on Geography and Food Resources, 777
Agriculture, Association of (Joint Biology Committee and the): Conference on Plant and Animal Breeding, 110
Agriculture, Association of, and others. Course on The Countryside, a Medium for Teaching, 549
Agriculture, Department of, Gold Coast. Appointment of L. Piening as plant pathologist, 333
Agriculture, Department of, Trinidad: Appointment of W. P. Unsworth as veterinary officer, 958
Agriculture for Scotland, Department of (Ministry of Agriculture and Fisheries and the): Postgraduate Scholarships, 596
Agriculture and Fisheries, Ministry of: Scholarships, 201
Agriculture and Fisheries, Ministry of, and the Department of Agriculture for Scotland: Postgraduate Scholarships, 596
Agriculture and Fisheries, Ministry of (Infestation Control Division), (Royal Sanitary Institute, in collaboration with the). Rodent Control Exhibition, 867
Ahmed, M. Bakr, and Twyman, Prof. E. S. Manganese Requirements of Tomato Plants at Different Phases of Growth, 438
Air Ministry, Meteorological Office: Annual Report of the Director of the Meteorological Office for the Year 1951–52, 293
  Climatological Atlas of the British Isles, *review* by Prof. Gordon Manley, 809
  Retirement of Sir Nelson Johnson from the directorship, 865
  Appointment of Prof. O. G. Sutton as director, 865
Aitken, Prof. A. C. Awarded the Gunning Victoria Jubilee Prize for 1948–52 of the Royal Society of Edinburgh, 867
Aitken, Dr. J. T.: Title of reader in anatomy at University College, London, conferred on, 678
Akhar, M. Abdel, and others: A New Procedure for Correlating the Structure of Glycosides, 474
Alexandrowicz, Dr. J. S.: Marine Biology Research, 828
Alim, Dr. K. A.: Longevity and Production in the Buffalo, 755
Allan, Dr. D. A.: Museums and Education, 1004
Allee, Prof. W. C.: Cooperation among Animals, *review* by Dr. W. H. Thorpe, 453
Allee, Prof. W. C., and Schmidt, Karl P.: Ecological Animal Geography, second edition, *review* by Charles Elton, 761
Allen, Dr. Clifford: A Psychiatrist's Credo, *review*, 232
  Mind and Life, *review*, 364
  The Neurotic in Society, *review*, 667
Allen, J. A.: Marine Biology Research, 828
  Function of the Foot in the Lucinacea (Eulamellibranchia), 1117
Allen, Dr. L. A.: Recent Advances in Microbiological Methods, 508
Allen, N. C. B., and Martin, Dr. L. H. (edited by): Exercises in Experimental Physics, *review*, 364
Allibone, Dr. T. E.: Appointed director of research to the Edison Swan Electric Co., 156
Allison, R. M.: Effect of Leaf Roll Virus Infection on the Soluble Nitrogen Composition of Potato Tubers, 573
Allsopp, Dr. C. B.: Appointed to the University of London chair of physics applied to medicine at Guy's Hospital Medical School, 822
Alten, Dr. F.: Soil Fertility and Crop Production, 68
Altmann, S. M., and Crook, Dr. E. M.: Activation of Enzymes by Chelating Agents, 76
Amatuzio, D. S., and Evans, Robert L.: Isotope Curves in Red Blood Cell Studies, 797
Amatuzio, D. S. (Evans, Robert L., and): Red-Cell Survival and Ashby Curves, 798
Ambartsumian, Prof. V. A.: Elected an associate of the Royal Astronomical Society, 678
Ambrose, D.: Standard Samples of Organic Substances for Physico-Chemical Measurements, 902
American Academy of Arts and Sciences: Rumford Bicentenary Celebrations, 376
  Rumford Medals awarded to Prof. E. Fermi, Prof. W. E. Lamb, jun., and Prof. L. Onsager, 376, 916
  Conference to celebrate the two-hundredth anniversary of the birth of Benjamin Thompson, Count Rumford, 915
  Election of Foreign Honorary Members, 1098
American Association for the Advancement of Science. Prize Awards, 65
American Association of Spectrographers: Symposium on Emission Spectroscopic Determination of Metals in Non-Metallic Samples, 66
American Bacteriologists, Society of: Publication of a new journal, *Applied Microbiology*, 638
American Chemical Society: A History of the (Charles Albert Browne and Mary Elvira Weeks), *review* by Sir Eric Rideal, 536
  Priestley Medal awarded to Sir Robert Robinson, 777
American Chemical Society (Rochester Section): Harrison Howe Lecture for 1953 (Prof. Herbert C. Brown), 1095
American Geophysical Union: William Bowie Medal awarded to Dr. Beno Gutenberg, 1139
American Institute of Electrical Engineers and the Institute of Radio Engineers: Conference on Electronic Digital Computers, 599
American Psychological Association: Study of Psychology in the United States, 110
American Society of Agronomy: Advances in Agronomy, Vol. 3 (edited by A. G. Norman), *review*, 946
American Society of Plant Physiologists: Committee to consider the Terminology of Plant Growth Regulators, 19
  Election of Prof. David R. Goddard as editor-in-chief of *Plant Physiology*, 1054
American Society for the Study of Sterility: Prize for a contribution to the subject of Infertility and Sterility, 156
American Society for the Study of Sterility (International Fertility Association in co-operation with the): First World Congress on Fertility and Sterility, 245
American Society for Testing Materials: Index of X-Ray Powder Diffraction Data, 155
American Telephone and Telegraph Co.: Frank B. Jewett Fellowship Awards, 332
Amery, L. S., and others: Parliament, a Survey, 183
Amos, S. W. (Godfrey, J. W., and): Sound Recording and Reproduction, *review*, 587
Amphlett, C. B.: Reduction of Ferric Ion in Aqueous Solution by γ-Radiation, 690
Anderson, A. M.: Appointed fisheries officer, Uganda, 421
Anderson, Carl D., and others: Science in Progress (edited by George A. Baitsell), Seventh Series, *review* by W. L. Sumner, 990
Anderson, Sir David: *Death* of, 774
Anderson, Dr. J. S.: Elected a Fellow of the Royal Society, 546
Andrade, Prof. E. N. da C.: Robert Hooke, 1635–1703, 365
Andreasen, Povl, and others: Magnetic Measurements in Deep-Sea Investigations—Magnetic Investigations on the *Galathea* Expedition, 384

Andrews, Dr. W. H. Horner, and Maegraith, Prof. B. G.: Anatomical and Physiological Evidence of Anastomosis of the Hepatic Artery and Hepatic Vein within the Mammalian Liver, 222
Angel, J. L.: Archæological Excavations in the Hotu Cave, Iran, 821
Angwin, Sir Stanley. Awarded the Faraday Medal of the Institution of Electrical Engineers, 287; work of, 287
Animal Technicians Association. Annual General Meeting, 638
Ansbacher, Dr. F., and Jason, Dr. A. C.: Effects of Water Vapour on the Electrical Properties of Anodized Aluminium, 177
Anson, M. L., and others (edited by): Advances in Protein Chemistry, Vol. 7, *review*, 276
Anti-Locust Research Centre: Report of the Director of the, 112
Appalanarasimham, N. (Asundi, Dr. R. K., and). Effect of Irradiation on the Intensity Distribution of the Second Positive Nitrogen Bands excited in a Nitrogen Ozonizer, 86
Arden-Close, Sir Charles. *Obituary* by Major-General M. N. MacLeod, 239
Argue, Dr. C. W.: Re-appointed a member of the National Research Council of Canada, 958
Arley, Dr. Niels (Iversen, Simon, and): Application of the Quantum Hit Theory to Tumours induced by Ultra-violet Radiation, 257
Arley, Dr. Niels, and others: Magnetic Measurements in Deep-Sea Investigations—Construction of Non-magnetic Containers, 383; Magnetic Investigations on the *Galathea* Expedition, 384
Armitage, P.: Effect of Nitrogen Mustard on an Inherited Character in the Rat, 1117
Armour, J.: Appointed veterinary officer, Nigeria, 958
Arnason, A. P., and others: Adsorption of DDT on Suspended Solids in River Water and its Role in Black-fly Control, 700
Arndt, Dr. U. W. (Riley, Dr. D. P., and). Raw Materials of Life, 144
Arnott, D. G., and Wells-Cole, J. A Rapid Method for the Extraction of Radio-iodide from Urine, 269
Arrol, Dr. W. J.: Handling of Radioactive and Toxic Substances, 294
Arthur, Prof. Paul, and Smith, Prof. Otto M.: Semimicro Qualitative Analysis, third edition, *review* by Dr. J. A. Muir, 1133
Artin, Emil, and others: Science in Progress (edited by George A. Baitsell), Seventh Series, *review* by W. L. Sumner, 990
Artom, Camillo. Role of Choline in the Oxidation of Fatty Acids by the Isolated Liver, 347
Arts, Royal Society of: Albert Medal for 1953 awarded to Dr. E. D. Adrian, 1005
Asami, Y., and Matsumoto, A.: High-frequency Electric and Magnetic Shielding, 957
Ashby, Dr. Eric: The Place of University Graduates in Industry, 871
Ashton, Hugh. The Basuto, *review* by G. I. Jones, 142
Ashwin, M. D.: Appointed agricultural officer, Nyasaland, 111
Asia (South) Science Co-operation Office. Bibliography of Scientific Publications of South Asia, No. 6, July–December 1951, 246
Asker, A. A., and others: Some Factors affecting Heat Tolerance of Cattle and Buffaloes, 1074
Asker, Dr. W., and others: Thermochromism and Keto-Enol Tautomerism of Solutions of 1 . 3-Diketo-2-phenyl-5-bromoindan, 222
Aslib. The Department of Scientific and Industrial Research and (G. Woledge and Leslie Wilson), 892
Aslib (Aeronautical Group): Second Annual Conference, 20
Aslib (Northern Branch). Conference at Stoke-on-Trent, 377
Aspden, H.: Awarded a Bowen Prize of the Scientific Instrument Manufacturers' Association of Great Britain by the Institute of Physics, 959
Astbury, Prof. W. T., and others: Electron Microscope Studies of the Structure of the Influenza Virus, 256
Astbury, Prof. W. T., and Saha, Dr. N. N.: Structure of Algal Flagella, 280
Astronomical Association, British: Annual General Meeting, 244
  Presidential Address (Dr. G. Merton), 244
  Election of E. H. Collinson as president, 244
  Walter Goodacre Medal and Gift presented to Frank Maurice Holborn, 244
Astronomical Society, Royal. Awards, 108
  Presentation of the Gold Medal to Dr. John Jackson, 379
  Election of Prof. V. A. Ambartsumian and Prof. A. Unsold as associates, 678
Astronomical Society, Royal, and the Geological Society: Geophysical Discussion on the Magnetic Properties of Rocks, 500
Asundi, Dr. R. K., and Appalanarasimham, N.: Effect of Irradiation on the Intensity Distribution of the Second Positive Nitrogen Bands excited in a Nitrogen Ozonizer, 86
Atherton, E.: Determinations of Size of Particles with the Electron Microscope, 350
Atkins, Dr. W. R. G.: *Obituary* of Prof. L. B. Smith, 196
  Marine Biology Research, 828
Atkins, Dr. W. R. G., and Jenkins, Miss P. G.: Marine Biology Research, 828
Atkinson, J. R.: Cosmic Rays and the Cloud Chamber, *review*, 495
Atomic Energy Research Establishment, Harwell: Report R/R 922, A Quantitative Study of Uranium-Graphite Lattices (Prof. E. A. Guggenheim and Prof. M. H. L. Pryce), revised edition edited by C. A. Rennie, 110
  Report R/L 5, Lecture Notes on Pile Theory (C. A. Rennie), 110
  Course on Electronic Instruments in Atomic Energy at the Isotope School, 290
  Symposium on the Handling of Radioactive and Toxic Substances, 294
  Further course of instruction at the Isotope School on the techniques of Using and Handling Radioactive Materials, 548
  Standard Solutions of Phosphorus-32, 1141
Atterling, Hugo, and Thulin, Sigvard: Beta-Spectrum of Arsenic-71, 927
Atterton, D. V., and Houseman, D. H.: Measurement of Temperatures of Metal/Mould Interfaces, 980
Audus, Prof. L. J.: Fate of Sodium 2,4-Dichlorophenoxy-ethyl-sulphate in the Soil, 523
Augustinsson, Dr. K.-B.: Bibliography on Cholinesterases and the Anti-cholinesterase Drugs, 729
Aurousseau, M.: Transliteration of Cyrillic Script, 940
Australian Government Department of Supply. Appointment of Dr. F. A. Fox as superintending scientist in charge of the Chemical and Physical Research Laboratories, 20
Australian National University: Award of Scholarships for work in the Department of Nuclear Physics, 156
  Appointment of Dr. B. D. McDaniel as a visiting Fulbright Fellow, and of Dr. J. H. Carver as a Research Fellow, in the Department of Nuclear Physics, 729
  Appointment of Dr. S. F. Mason as a Research Fellow of the Department of Medical Chemistry in London, 777
Australian and New Zealand Association for the Advancement of Science: Thirtieth Meeting, 1142
Avicenna, Scientist and Philosopher (edited by G. M. Wickens), *review* by F. L. G. Rawlins, 188
Axelrod, D. I., and others: The Problem of Land Connections across the South Atlantic, with special reference to the Mesozoic, 669

BAAL, H. J.: Behaviour of Spider Crabs in the Presence of Octopuses, 887
Bacci, Dr. Guido, and La Greca, Dr. Marcello: Genetic and Morphological Evidence for Subspecific Differences between Naples and Plymouth Populations of *Ophryotrocha puerilis*, 1115
Backman, Prof. E. Louis: Religious Dances in the Christian Church and in Popular Medicine, translated by E. Classen, *review* by M. C. Burkitt, 667
Bacon, Dr. J. S. D.: Appointed senior lecturer in biochemistry at the University of Sheffield, 20
  The Role of Vitamins in Metabolic Processes, 456
Bacteriology (Applied), Society for: Symposium on Antibiotics, their Production and Uses in Industry, 914
Bacteriology (Applied), Society for, and the Microbiological Group of the Society of Chemistry and Industry: Discussion on Recent Advances in Microbiological Methods, 507
Baddiley, Dr. J., and others: Structure of Coenzyme A, 76
Badenhuizen, Prof. N. P.: University Botanical Teaching and Training, 314
Baertschi, P., and others: Fractionation of Isotopes by Distillation of some Organic Substances, 1018
Baeyer, Adolf von, 1835–1917 (Karl Schmorl), *review* by Prof. John Read, 319
Bagchi, S. N. (Hosemann, R., and): Calculation of Electron-Density Distribution in Crystals with the Help of Convolution Operations, 785
Bailey, D. K.: Appointed geologist, Northern Rhodesia, 111
Bailey, Sir Edward: Geological Survey of Great Britain, *review* by Sir Arthur Trueman, 96
  Albert Heim (1849–1937), *review*, 1036
Bailey, Dr. Kenneth: Elected a Fellow of the Royal Society, 546
Bailey, Dr. Kenneth, and others (edited by): Advances in Protein Chemistry, Vol. 7, *review*, 276
Bailey, Dr. L.: Effect of Fumagillin upon *Nosema apis* (Zander), 212
Bailey, P. B. H.: Appointed geologist, British Guiana, 111
Baillaud, Jules. Elected a member of the Astronomy Section of the Paris Academy of Sciences, 20
Baird, P. D.: Awarded the Founder's Medal of the Royal Geographical Society, 635
Baitsell, George A. (edited by): Science in Progress (Bradley M. Patten, George W. Corner, Arnold Gesell, H. J. Muller, T. M. Sonneborn, Ralph W. G. Wyckoff, Carl D. Anderson, Farrington Daniels, J. R. Dunning, Emil Artin, George Gaylord Simpson, Raymond M. Fuoss), Seventh Series, *review* by W. L. Sumner, 990
Baker, A., and others: Social Psychiatry, *review* by Dr. Clifford Allen, 667
Baker, Prof. W.: Substances naturelles de synthèse, *review*, 496
Balakrishnan, S., and Rajagopalan, Dr. R.: Influence of Sulphaguanidine on the Intestinal Flora and Thiamine Synthesis brought about by Curd Feeding, 608
Balfour, Sir Isaac Bayley (1853–1922), 548
Ball, L. E.: Education in Chemistry, 466
Ballinger, H. A., and others: Neutron Detectors for Reactor Instrumentation, 412
Baló, Prof. J. (Banga, I., and): Elastin and Elastase, 44
Balz, Prof. Albert G. A.: Descartes and the Modern Mind, *review* by L. J. Beck, 277
Bamford, Dr. C. H.: Amino Acids and Proteins, *review*, 765
Bamford, Dr. C. H., and others: $\beta$-Forms of Fibrous Proteins and Synthetic Polypeptides, 1149

Brindley, Dr. G. W.: Clay–Water Relationships, 681, 682, 683
Bristol City Museum: Oil Exhibition (Shell Petroleum Co., Ltd.), 677
British Agricultural Engineers, Institution of: Scholarship, 333
  Election of David P. Ransome as president for 1953–54, 777
British Agricultural History Society: First General Meeting, 420
  Inaugural Conference, 775
British Association for the Advancement of Science: *Endeavour* Prizes for Science Essays, 421
  Alexander Pedler Lecture (Sir Harold Hartley), 867, 1040
  Liverpool Meeting of the, 901
British Association for the Advancement of Science, Section A (Physics and Mathematics): Discussion on the Physics of the High Atmosphere, 146
British Association for the Advancement of Science, Section J (Psychology): Discussion on some Social and Psychological Problems of Ageing, 422
British Association of Chemists: Hinchley Medal awarded to Dr. Herbert Levinstein, 333
  Opening of new headquarters at Hinchley House, 425
British Association of Chemists (London Section) and the London Section of the Royal Institute of Chemistry: Discussion on Education in Chemistry, 156, 465
British Astronomical Association: Annual General Meeting, 244
  Presidential Address (Dr. G. Merton), 244
  Election of E. H. Collinson as president, 244
  Walter Goodacre Medal and Gift presented to Frank Maurice Holborn, 244
British Caribbean Meteorological Service, Trinidad: Appointment of K. V. W. Nicholls as senior meteorologist, 201
  Appointment of M. Garstang as assistant meteorologist, 958
British Chemical Manufacturers, Association of: Press Guide to British Chemicals and their Manufacturers, 821
British Columbia Research Council: Appointment of new members, 421
British Commonwealth Geological Liaison Office, 598
British Council: Report for the Year 1951–52, 69
British Electrical and Allied Industries Research Association: Thirty-second Annual Report, 1145
British Electrical and Allied Industries Research Association, and others: Conference on Ionization Phenomena in Discharges, 463
British Engine Boiler and Electrical Insurance Co., Ltd.: Technical Report, New Series, Vol. 1, 510
British Gelatine and Glue Research Association: Sixth Meeting of the Research Panel, 250
  Re-election of G. W. Odey as chairman, 250
  Annual Reports for 1951 and 1952, 918
  Residential Conference (A. G. Ward), 1099
British Hydromechanics Research Association: Appointment of R. C. Worster as deputy director of research, 1054
British Industries, Federation of: Report of the Conference on Industry and the Universities organized by the F.B.I. North Midland Regional Council and the University of Nottingham, September 1952, 962
British Industries, Federation of, and the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom: Report of the Universities and Industry Conference, October 1952, 870
British Iron and Steel Research Association: Appointment of M. W. Thring as an assistant director of research, 290
British Museum (Natural History): Fossil Mammals of Africa, No. 4, Miocene Anthracotheriidae from East Africa (D. G. MacInnes), 505; No. 5, The Miocene Lemuroids of East Africa (Prof. W. E. Le Gros Clark and D. P. Thomas), 505
British Mycological Society: Symposium on the Physiological Relationship of Host Plant and Parasite, 22
British Non-Ferrous Metals Research Association: Opening of the laboratories for inspection, 463
  Open Days, 731
British Ornithologists' Union: Check-List of the Birds of Great Britain and Ireland, 781
British Rubber Producers' Association: Appointment of Dr. L. C. Bateman as director of research, 1098
British Society for the History of Science (Philosophy of Science Group): Prize for an essay on the Universe, 1098
British Society of Rheology: Symposium on Elasticity in Liquids, 778
British Sociological Association: Conference on Social Policy and Social Sciences, 463, 823
British Steel Castings Research Association: Formation of, 548
  Appointment of J. F. B. Jackson as director, 548
British Welding Research Association: Summer School on Welding and Fabrication, 111

Carmichael, Dr. J: Insecticides and Colonial Agricultural Development, 825
Carmichael, Dr. L. Diffusion of Knowledge, 866
Carnegie Institution of Washington: Report of the President for the Year ending June 30, 1952 (Dr Vannevar Bush), 424
  Appointment of Dr. P. H. Abelson as director of the Geophysical Laboratory, 594
Carpenter, Prof. G. D. Hale: *Death* of, 241, *obituary* by Dr. B M. Hobby, 592
Carr, Sir Cecil, and others: Parliament, a Survey, 183
Carrington, Hereward. Psychic Oddities, *review* by Dr. E. J. Dingwall, 320
Carse, Duncan: Awarded the Cuthbert Peek Grant of the Royal Geographical Society, 636
Carter, Dr. G. S.: Hydrobiology and Inland Fisheries of Africa, 291
Cartwright, K. St. G., and Findlay, Dr W. P. K. Dry Rot in Wood, fifth edition, 1053
Carver, Dr. J. H.: Appointed a Research Fellow in the Department of Nuclear Physics, Australian National University, Canberra, 729
Cass, W. G.: Abstracting and Library Work in the U S S.R., 555
Casselman, Dr. W. G. B.: Awarded a Merck Fellowship by the National Research Council, Ottawa, 1054
Cassels, John M.: The Sterling Area, an American Analysis, *review* by Mrs. Ursula K. Hicks, 537
Cassie, Prof. W. Fisher: *Obituary* of Prof. C J. Hawkins, 372
Cassirer, Ernst: The Philosophy of the Enlightenment, translated by Fritz C. A. Koelln and James P. Pettegrove, *review* by F. I. G. Rawlins, 900
Caster, K. E., and others The Problem of Land Connexions across the South Atlantic, with special reference to the Mesozoic, 669

Castillo, Dr. J. del, and Katz, Prof. B.: Statistical Nature of 'Facilitation' at a Single Nerve-Muscle Junction, 1016
Cawood, Dr. W.: Appointed principal director of scientific research (defence) in the Ministry of Supply, 330; work of, 330
Cell Biology, International Society for: Eighth International Congress, 421
Cement and Concrete Association: Donation of £2,500 to the Department of Civil Engineering, University of Leeds, 421
Chadwick, Sir James: Appointed Rutherford Lecturer for 1953 of the Royal Society, 290
Chakravarti, S. C.: Organization of Shoot Apex during the Ontogeny of *Brassica campestris* L., 223
Challenger, Prof. F.: Retirement from the chair of organic chemistry in the University of Leeds, 418, work of, 418
Challenger Society: Grants in aid of Research in Marine Biology or Oceanography, 1054
Chaloner, W. G.: Awarded a Commonwealth Fund Fellowship for Study in the United States, 777
Chamberlain, Dr. E. A. C.: Elected a Fellow of the Royal Society of Edinburgh, 418
Champy, Prof. Christian: Elected a member of the Anatomy and Zoology Section of the Paris Academy of Sciences, 638
Chandler, Commander P.: Protection from the Effects of Radiation, 379, 777
Chandler, R. D. T. E.: Appointed chemist, Federation of Malaya, 111
Chandraratna, Dr. M. F.: A Gene for Photoperiod Sensitivity in Rice linked with Apiculus Colour, 1162
Chandrasekhar, Prof. S.: Awarded the Gold Medal of the Royal Astronomical Society, 108
Chant, S. R.: Appointed plant pathologist, Nigeria, 201
Chapman, Prof. Sydney. Retirement from the Sedleian chair of natural philosophy in the University of Oxford, 911, work of, 911
Chapman, Prof. V. J.: University Botanical Teaching and Training, 314
Charl, A., and Wertheimer, E.: Effect of Acetoacetate on Glycogen Synthesis and Glucose Utilization in the Isolated Rat Diaphragm, 44
Charles, Arwyn: Uptake of Dyes into Cut Leaves, 435
  Apparatus for Infiltration of Liquids into Leaves, 1166
Charlesby, Dr. A.: Effect of High-energy Radiation on Long-chain Polymers, 167
Charlesby, Dr. A., and Ross, M.: Breakdown of Methyl Methacrylate Polymer by High-Energy Radiation, 1153
Charlwood, Dr. P. A. (Warren, Dr. R. L., and): Photoelectric Control of the Compensator in Electrophoresis, 353
Chase, F. E., and Gray, Prof. P. H. H.: Use of the Warburg Respirometer to study Microbial Activity in Soils, 481
Chatterjee, S. N. (Mukerji, S., and). Permeability of Insect Cuticle to Aqueous Stains and Vulnerability to Insecticides, 119
Chaudhuri, Dilip K. Roy (Bose, Dr. Ajay K., and): Conformation of Tropane Alkaloids, 652
Chayen, J., and Norris, K. P.: Cytoplasmic Localization of Nucleic Acids in Plant Cells, 472
Chayen, J., and others: Cytoplasmic Particles in Bean Root Cells, 1113
Chemical Industry, Society of (Crop Protection Panel of the Agriculture Group): Discussion on Physical Factors in relation to Biological Activity of Insecticides, 869
Chemical Industry, Society of (Food Group), and others: Symposium on Flavour Assessment, 724
Chemical Industry, Society of (Nutrition Panel of the Food Group): Series of meetings on Food and the Future, 160
  Discussion on Newer Sources of Foodstuffs, 917, *errata*, 1098
Chemical Industry, Society of (Oils and Fats Group): Symposium on the Oxidation of Oils and Fats, 678, 1057
Chemical Industry, Society of, and the Institute of Petroleum: Symposium on Production and Utilization of Petroleum Raw Materials in the U.K. Chemical Industry, 679
Chemical Manufacturers (British), Association of. Press Guide to British Chemicals and their Manufacturers, 821
Chemical Society. Centenary Lecture (Prof. A. Tiselius), 290
  Election of Officers, 678
Chemistry, Royal Institute of, and the Society of Public Analysts and other Analytical Chemists: Summer School in Analytical Chemistry in the Royal College of Science and the Royal School of Mines, 333
Chemistry, Royal Institute of (London Section) (London Section of the British Association of Chemists and the). Discussion on Education in Chemistry, 156, 465
Chemistry and Industry, Society of (Microbiological Group), and the Society for Applied Bacteriology: Discussion on Recent Methods in Microbiological Methods, 507
Chemists, British Association of: Hinchley Medal awarded to Dr. Herbert Levinstein, 333
  Opening of new headquarters at Hinchley House, 425
Chemists, British Association of (London Section) and the London Section of the Royal Institute of Chemistry. Discussion on Education in Chemistry, 156, 465
Chen, Mrs. Y. T., and others: Synthesis of L-Ascorbic Acid in Plants and Animals, 348
Chermin, H. A. G., and others: Optical Exaltation in Aromatic Compounds, 1075
Chesters, Prof. C. G. C.. Elected a Fellow of the Royal Society of Edinburgh, 419
Chhapgar, A. F., and others: Piezo-electric Oscillations of Quartz Plates at Even and Half-odd Harmonics, 216
Chiang, Y., and others. Bibliography of Differential Thermal Analysis, 244
Chimie Industrielle, Société de: Second Salon de la Chimie, 776
Chimie Physique, Société de: Discussion on Recent Advances in the Study of Molecular Structure, 914
Chippendale, R. A. (Jenkins, J. A., and): Awarded a Radio Industry Council Premium for Technical Writing, 463
Chopard, Prof. Lucien: Faune de France, 56, Orthoptéroides, *review* by David R. Ragge, 626

Radio Industry Council : Awards for Technical Articles on Radio, 200, 463
Radio Union : International Scientific—Meeting in Sydney (Dr. R. L. Smith-Rose), 628
Radiophysics Laboratory, Sydney : Research Activities of the (Commonwealth Scientific and Industrial Research Organization), 1053
Rae, F. H. : Physical Factors in relation to Biological Activity of Insecticides, 870
Rae, K. S. M : Elected a Fellow of the Royal Society of Edinburgh, 419
Raffles Museum, Singapore : Appointment of Prince John Loewenstein as curator of anthropology, 111
Ragab, M. T., and others : Some Factors affecting Heat Tolerance of Cattle and Buffaloes, 1074
Rageth, H. W. J. (Wassink, E. C., and) : Chromatography of Phycocyanin, 376
Ragge, David R. : Orthopteroid Insects of France, *review*, 626
Railing, Sir Harry : Elected to honorary membership of the Institution of Electrical Engineers, 287 ; work of, 287
Raine, H. C. : Production and Utilization of Petroleum Raw Materials in the U.K. Chemical Industry, 680
Rains, A. B. : Appointed pasture research officer, Nigeria, 111
Rains, A. J. H., and Crawford, N. : Formation of Gall Stones—Physical Properties of Bile Salts, 829
Rast, J. R., and others : Economic Aspects and Administration of an Industrial Radiology Department, 114
Raj, H. Gurubasava (Datta, N. P., and) : Effect of Boron and Molybdenum Fertilizers on Berseem (*Trifolium alexandrinum*), 134
Rajagopalan, Dr. R. (Balakrishnan, S., and) : Influence of Sulphaguanidine on the Intestinal Flora and Thiamine Synthesis brought about by Curd Feeding, 608
Ramage, C. S. : Awarded a Colonial Civil Service Fellowship, 777
Ramaiah, N. A., and others : Langmuir Adsorption as a Determinant of Conductivity in a Low-frequency Electric Discharge, 929
Ramakrishna, B. S. (Rao, S. K. Lakshmana, and) : A Trigonometric Series used in Physical Problems, 308
Ramsbottom, Dr. J. : The Nature Conservancy, 591
  Elected president of the Society for the Bibliography of Natural History, 637
Randall, L. D. : Appointed statistician, East Africa High Commission, 201
Randall, Prof. J. T. : Developments in Methods of Microscopy, 730
Randall, Prof. Robert H. : An Introduction to Acoustics, *review*, 142
Rankin, Jesse J. : A New Technique for Microscopic Preparations of Small Marine Animals, 35
Rannie, J. : Awarded the William J. Larke Medal for 1952 of the Institute of Welding, 377
Ransome, David P. : Elected president for 1953–54 of the Institution of British Agricultural Engineers, 777
Rao, Dr. B. Ramachandra, and Rao, K. Subba : A New Precision Method for the Measurement of Ultrasonic Velocities in Liquids, 1077
Rao, K. Subba (Rao, Dr. B. Ramachandra, and) : A New Precision Method for the Measurement of Ultrasonic Velocities in Liquids, 1077
Rao, N. S., and Datta, R. M. : Chromosomes of the Genus *Corchorus*, 754
Rao, S. K. Lakshmana, and Ramakrishna, B. S. : A Trigonometric Series used in Physical Problems, 308
Rask-Nielsen, Dr. R. : Awarded a Scholarship of the Lady Tata Memorial Trust, 1098
Rasmussen, Erik : Asexual Reproduction in *Pygospio elegans* Claparède (*Polychaeta sedentaria*), 1161
Ratcliffe, J. A. : Awarded the Holweck Medal and Prize for 1953, 678
Ratkovszky, F. : Awarded a Kossuth Prize for 1953, 1010
Rauss, Prof. K. : Awarded a Kossuth Prize for 1953, 1010
Rawlins, F. I. G. : Avicenna, Scientist and Philosopher, *review*, 188
  The Philosophy of the Enlightenment, *review*, 900
  The Birth of Neo-Positivism, *review*, 947
  Leibniz und das Reich der Gnade, *review*, 992
  A Harmony of Proportions, *review*, 1037
  Introduction to Metamathematics, *review*, 1039
Rawlins, F. I. G., and Werner, Dr. A. E. : Scientific Method and the Art Gallery, 199
Rawlins, Prof. George M., and Struble, Alden H. : Chemistry in Action, second edition, *review* by G. P., 1039
Rawson, Dilys : Spermatogenesis in *Lumbricus terrestris* L., Müll., 264
Rawson, H. : Internal Stresses caused by Disorder in Vitreous Materials, 169
Ray, Dr. D. B. : Awarded a Frank B. Jewett Fellowship by the American Telephone and Telegraph Co., 332
Raybould, Dr. S. G. : Appointed to the chair of adult education in the University of Leeds, 548 ; work of, 548
Raymont, Prof. J. : Marine Biology Research, 828
Raynaud, M., and Wright, E. A. : Rapid Specific Preventive Action of Tetanus Toxoid, 797
Raynor, Prof. G. V. : Address at the Fortieth Anniversary of the Discovery of X-Ray Diffraction, 106
Raynor, Prof. G. V. (Berry, R. L. P., and) : Structure of Magnesium-Lithium β-Phase Alloys, 1078
Read, Prof. John : The Terpenes, *review*, 233
  Adolf von Baeyer, Chemist and Man, *review*, 319
  Natural Origin of Optically Active Substances and Optical Resolution by Symmetric Agents, 843
  Lectures in Dutch Universities, 914
Read, W. H. : Physical Factors in relation to Biological Activity of Insecticides, 870
Reardon, Edward J. (Van Hook, Prof. Andrew, and) : Liesegang Rings on Metallic Bases, 177
Redmayne, Sir Richard : Presidential Address to the Institution of Professional Civil Servants, 1003
Reece, A. W. : Appointed geologist, Uganda, 333
Reece, W. W. : Appointed stock development officer, North Borneo, 201
Reed, Dr. R., and others : Electron Microscope Studies of the Structure of the Influenza Virus, 256
Rees, A. M. M. : Appointed agricultural economist, Northern Rhodesia, 333
Rees, C. B., and others : *Calanus finmarchicus* and related Forms, 1163
Rees, T. D. : Appointed geochemist, Geological Survey Department, Tanganyika, 678
Reeve, E. C. R., and Robertson, F. W. : Analysis of Environmental Variability in Quantitative Inheritance, 874
Reeves, Dr. H. G. : *Obituary* by Prof. A. Wormall, 329
Regional Library Bureaux (National Central Library and the) : Library Co-operation in Great Britain, Report of the (Robert F. Vollans), 1144
Rehman, M. A. : Seasoning Behaviour of Indian Timbers, 504
Rehman, M. A., and Kishen, Jai : Deodar as Pencil Wood, 732
Reichlin, S., and others : The Thyroid Gland, 552
Reid, D. M. : A New School Biology, *review*, 279
  Elected an associate *honoris causa* of the Linnean Society of London, 1003
Reid, Elizabeth (Fenwick, David W., and) : Seasonal Fluctuations in the Degree of Hatching from Cysts of the Potato Root Eelworm, 47
Rein, Prof. H. : *Death* of, 1139
Reiss, Dr. M. : The Thyroid Gland, 552
Reitemeier, Dr. R. F. : Soil Fertility and Crop Production, 67
Reith, Dr. J. W. S. : Soil Fertility and Crop Production, 68
Rennie, C. A. : Lecture Notes on Pile Theory, 110
Rennie, S. D. (Cromwell, Dr. B. T., and) : Occurrence of Choline Oxidase in Plant Tissues, 79
Research Associations : Finances of, 503
Research Development Corporation, National : Report for the Year 1951–52, 826
Reumatologia, Società Italiana di : Symposium on Cortisone and the Suprarenal Cortex, 463
Reyes, A., and others : Anti-diuretic and Oxytocic Substances liberated by the Digestion of Plasmatic Proteins with Pepsin, 82
Reynolds, P. M., and Verma, Ajit Ram : Growth and Optical Properties of Stearic Acid Crystals, 486
Reynoldson, Dr. T. B. : Habitat of *Polycelis felina* (= *cornuta*) and *Crenobia alpina* in the British Isles, 660
Rheology, British Society of : Symposium on Elasticity in Liquids, 778
Rhodes, Dr. P. : The Band Theory of Metals, 1056
Rhys-Jones, D. C., and others : Plastic Properties of Coking Coals, 389
Ricardo, Sir Harry : Awarded the James Watt International Medal for 1953 of the Institution of Mechanical Engineers, 66
Richard, H. : Geophysical Prospecting, 202
Richards, F. J. : Degree of D.Sc. of the University of Birmingham conferred on, 246
Richards, H. J. : Appointed geologist, Nigeria, 111

Richards, H. R., and Speakman, Prof. J. B. : Iodination of Keratin, 751
Richards, Merfyn : Saprophytic *Cladosporium* in Britain, 615
Richards, Prof. P. W. : Flora and Vegetation of Ireland, *review*, 1085
Richardson, Dr. E. G. : The Teaching of Acoustics, 21
  Elasticity in Liquids, 778
Richardson, Dr. H. L. : Soil Fertility and Crop Production, 68
Riches, J. P., and Gooding, E. G. B. : Physiology of Rubber Tapping, 461
Rideal, Sir Eric : The American Chemical Society, 1876–1951, *review*, 536
  The Life and Work of Rumford, 540
  *Obituary* of Prof. J. W. McBain, 674
  Chemistry and Physics in Spain, 915
  Appointed chairman of the Advisory Council on Scientific Research and Technical Development of the Ministry of Supply, 959
Ridout, M. S. : Height of the Potential Barrier in Barrier Layer Cells, 219, *erratum*, 246
Riehm, Dr. H. : Soil Fertility and Crop Production, 68
Riesz, Frederick : Awarded a Kossuth Prize for 1953, 1010
Riet Lowe, Dr. C. van : The Pleistocene Geology and Prehistory of Uganda, Part 2, Prehistory, *review* by M. C. Burkitt, 4
Rigby, Dr. G. R., and others : An Unusual Form of Carbon, 756
Riley, Dr. D. P., and Arndt, Dr. U. W. : Raw Materials of Life, 144
Riley, N. D. : *Obituary* of Dr. K. G. Blair, 152
Rimington, Prof. C. : Haemoglobin Metabolism, 464
Rimington, Prof. C. (Cookson, G. H., and) : Porphobilinogen—Chemical Constitution, 875
Ring, J., and Wilcock, Dr. W. L. : Multi-layer Dielectric Reflecting Films at Wave-lengths between 4000 and 4600 A., 648
Ripper, Dr. W. E. : Biology as a Career, 251
Ritchie, A. B. : Handling of Radioactive and Toxic Substances, 294
Ritchie, A. C., and others : Latent Carcinogenic Action of Beta-Irradiation on Mouse Epidermis, 934
Ritson, Prof. J. A. S. : Retirement from the University of London chair of mining at the Royal School of Mines, 153 ; work of, 153
Rivers, Mrs. R. Pitt : The Thyroid Gland, 552
Rivet, Paul, et Créqui-Montfort, Georges de : Bibliographie des langues aymará et kičua, *review* by Dr. G. H. S. Bushnell, 1133
Rivett, D. E. A., and others : Fluoroacetate Poisoning—Comparison of Synthetic Fluorocitric Acid with the Enzymically Synthesized Fluorotricarboxylic Acid, 1111
Riviere, A. C. : Awarded an Australian National University scholarship for work in the Department of Nuclear Physics, 156
Roach, Dr. F. E. : Physics of the High Atmosphere, 146
Roach, Dr. W. A. : Soil Fertility and Crop Production, 68
Rob, Prof. G. C. : Preservation of Normal Tissues for Transplantation, 1049
Roberts, D. K. : Resignation as lecturer in mechanical engineering and sub-warden of Ranmoor House at the University of Sheffield, 959
Roberts, F. A. (Dennison, A. T., and) : Geophysical Prospecting, 202
Roberts, F. M. (Nutman, Dr. F. J., and) : Sudden-Death Disease of the Clove Tree, *Eugenia aromatica*, 128
Roberts, Dr. L. E. J. (Dresel, Miss E. M., and) : Closed Pores in Synthetic Graphite, 170
Robertson, F. W. (Reeve, E. C. R., and) : Analysis of Environmental Variability in Quantitative Inheritance, 874
Robertson, R. H. S. : Clay–Water Relationships, 682, 683
Robertson, Dr. R. N., and others : The Mitochondrial Membrane, 401
Robin, G. de Q. : Measurements of Ice Thickness in Dronning Maud Land, Antarctica, 55
  Awarded the Back Grant of the Royal Geographical Society, 636
Robineaux, Dr. R. : Awarded a Scholarship of the Lady Tata Memorial Trust, 1098
Robinson, Dr. E. : Appointed lecturer in the Department of Botany, University of Leeds, 549
Robinson, Dr. E., and Brown, Dr. R. : Cytoplasmic Particles in Bean Root Cells, 313
  Enzymic Systems in Root Apices, 636
Robinson, J. T. : The Nature of *Telanthropus capensis*, 33
Robinson, Sir Robert : Production and Utilization of Petroleum Raw Materials in the U.K. Chemical Industry, 681
  Awarded the Priestley Medal of the American Chemical Society, 777
Robson, Stanley : Elected secretary of the Royal Institution, 290
Robson, Prof. William A. : Problems of Nationalized Industry, 448
Roche, Prof. Jean : Chemistry and Inter-Relationships of Endocrine Systems and their Psychological Effects, 509
  The Thyroid Gland, 551
Rochester, G. D., and Wilson, J. G. : Cloud Chamber Photographs of the Cosmic Radiation, *review* by J. R. Atkinson, 495
Rockefeller Foundation : The Story of the (Raymond B. Fosdick), 987
Rockley, J. C. : Training in Industrial Radiology, 114
Rodger, Prof. Ferguson : Social Policy and the Social Sciences, 823
Rodgers, III, Andrew Denny : Erwin Frink Smith, a Story of North American Plant Pathology, *review*, 764
Roemer, Dr. M. I. : Social Policy and the Social Sciences, 823
Rogers, Dr. C. A. : Title of reader in mathematics in the University of London conferred on, 1054
Rogers, Dr. D. : Alleged Optical Activity in Crystal Class *m*, 929
Rogers, Lindsay, and others : Government Assistance to Universities in Great Britain (Memoranda submitted to the Commission on Financing Higher Education), 273
Rogerson, A. : Appointed scientific officer, East Africa High Commission, 421
Rojas, G., and others : Anti-diuretic and Oxytocic Substances liberated by the Digestion of Plasmatic Proteins with Pepsin, 82
Rollefson, G. K., and Powell, R. E. (edited by) : Annual Review of Physical Chemistry, Vol. 3, *review* by Dr. H. A. Skinner, 364
Roman, Dr. W. : *Obituary* of Dr. Franz K. Nagelschmidt, 17
Romer, Prof. A. S. : Elected a Foreign Member of the Linnean Society of London, 1003
Romer, Prof. A. S., and others : The Problem of Land Connections across the South Atlantic, with special reference to the Mesozoic, 669
Romwalter, Prof. A. : Awarded a Kossuth Prize for 1953, 1010
Rook, J. A. F. (Blaxter, K. L., and) : Indirect Determination of Water Retention in Cattle as a means of estimating Energy Exchange, 609
Rooksby, Dr. H. P. : Clay–Water Relationships, 683
Roscoe, Dr. R. : Elasticity in Liquids, 778
Rose, Dr. Arnold M. : Awarded a Prize of 1,000 dollars offered by the American Association for the Advancement of Science for an essay on theoretical sociology, 65
Rose, W. V. : Appointed deputy director of agriculture, Barbados, 958
Rosenbach, O. : Geophysical Prospecting, 202
Rosenberg, Edith, and others : Effect of Hyaluronidase on the Mortality from Experimental Burns, 431
Rosenhead, Prof. L. : Appointed a member of the Advisory Council on Scientific Research and Technical Development, 1095
Ross, A. H. H. : Appointed director of forestry for Scotland, 596
Ross, Prof. Alan S. C. : Structural Linguistics, *review*, 1084
Ross, E. J. : Insulin and the Permeability of Cell Membranes to Glucose, 125
Ross, Helen E., and others : Effect of L-Glutamic Acid Analogues on the Enzymatic Formation of Hydroxamic Acid, 45
Ross, K. F. A., and others : Refractometry of Living Cells, 720
Ross, M. (Charlesby, Dr. A., and) : Breakdown of Methyl Methacrylate Polymer by High-Energy Radiation, 1153
Ross, Dr. W. C. J. : Appointed to the University of London readership in chemistry at the Institute of Cancer Research (Royal Cancer Hospital), 333
Ross Institute of Tropical Hygiene : Course in Tropical Hygiene for Laymen, 333
Rossby, Prof. Carl-Gustav : Awarded the Symons Memorial Medal for 1953 of the Royal Meteorological Society, 866
Roston, Dr. B. : A Theoretical Approach to the Problem of determining the Relationship between the Constants of Circuits and their Intrinsic Safety, 397
Roth, Jay S. : Effect of Sulphydryl Reactants on Liver Ribonuclease, 127
Roth, L. : Descartes, *review*, 1083
Rothamsted Experimental Station : Report for 1951, 780
Rothé, Prof. J. P. : The Floor of the Atlantic Ocean, 859
Rothschild, Lord : A New Method of Measuring Sperm Speeds, 512
  Elected a Fellow of the Royal Society, 547
  Re-appointed chairman of the Agricultural Research Council, 1054
Rothwell, P. : Noise from Aircraft at Supersonic Speeds, 215
Rowland, Dr. P. R. : Mechanism of Electro-polishing, 931
Rowley, D. : Inhibition of *E. coli* Strains by Amino-Acids, 80
Rowson, L. E., and others : Influence of Ovarian Hormones on Uterine Infection, 749
Royal Aeronautical Society : Election of Sir William Farren as president, 635
Royal Aeronautical Society (Acoustics Group of the Physical Society and the) : Discussion on Aeronautical Acoustics and Jet Noise in particular, 914
Royal Agricultural Society of New South Wales : Election of Prof. W. L. Waterhouse as an honorary life member, 20
Royal Astronomical Society : Awards, 108
  Presentation of the Gold Medal to Dr. John Jackson, 379
  Election of Prof. V. A. Ambartsumian and Prof. A. Unsold as associates, 678
Royal Astronomical Society and the Geological Society : Geophysical Discussion on the Magnetic Properties of Rocks, 500
Royal Botanic Gardens, Kew : Centenary of the Herbarium and Library, 1086
Royal Cancer Hospital : Appointment of Dr. W. C. J. Ross to the University of London readership in chemistry at the Institute of Cancer Research, 333
  Appointment of Dr. J. A. V. Butler to the University of London chair of physical chemistry at the Chester Beatty Research Institute, 503
  Appointment of Dr. L. F. Lamerton to the readership in physics applied to medicine at the Institute of Cancer Research, 777
Royal College of Science and the Royal School of Mines : Summer School in Analytical Chemistry (Royal Institute of Chemistry and the Society of Public Analysts and other Analytical Chemists), 333
Royal Commission on Awards to Inventors : Third Report, 467
Royal Dublin Society : *Scientific Proceedings* of the, Vol. 26 (N.S.), No. 1, Fitzgerald Memorial Number, 206
Royal Dutch-Shell Group : Research Studentship in Geophysics, 729
  Booklets on Careers in the Petroleum Industry, 1004
Royal Geographical Society : Awards, 635
Royal Geographical Society and the National Institute of Oceanography : Exhibition entitled Exploring the Sea, 65
Royal Institute of Chemistry (London Section) (London Section of the British Association of Chemists and the) : Discussion on Education in Chemistry, 156, 465
Royal Institute of Chemistry and the Society of Public Analysts and other Analytical Chemists : Summer School in Analytical Chemistry in the Royal College of Science and the Royal School of Mines, 333
Royal Institution : Election of Stanley Robson as secretary, 290
  Appointment of Sir Lawrence Bragg as Fullerian professor of chemistry, resident professor and director of the laboratories, 819
  Election of Officers, 819
Royal Meteorological Society : Symons Memorial Medal awarded to Prof. Carl-Gustav Rossby, 866
Royal Microscopical Society : Conversazione, 959
Royal Microscopical Society (Industrial Section), and others : Discussion on Developments in Microscopical Methods, 245, 730
Royal Observatory, Cape of Good Hope : Report for 1951, 161
Royal Observatory, Greenwich : Historic buildings to be taken over by the National Maritime Museum, 374
  Observations at the, 1009
Royal Photographic Society : Centenary Celebrations, 108
  Centenary Exhibition of prints and photographic apparatus at the Science Museum, 290
Royal Photographic Society (Scientific and Technical Group) : Conference on Photographic Science and Technique, 777, 1143
Royal Sanitary Institute : Appointment of P. Arthur Wells as secretary, 20
  Annual Health Congress, 244
Royal Sanitary Institute, in collaboration with the Infestation Control Division of the Ministry of Agriculture and Fisheries : Rodent Control Exhibition, 867

Royal School of Mines : Retirement of Prof. J. A. S. Ritson from the University of London chair of mining, 153
  Appointment of Prof. J. C. Mitcheson to the University of London chair of mining, 154
Royal School of Mines (Royal College of Science and the) : Summer School in Analytical Chemistry (Royal Institute of Chemistry and the Society of Public Analysts and other Analytical Chemists), 333
Royal Scottish Forestry Society : Centenary Endowment Fund, 727
Royal Scottish Museum, Edinburgh : Panorama of Metals in the Service of Man, 1053
Royal Society : Mackinnon Research Studentships awarded to R. C. Jennison and Dr. F. K. Duxbury, 66
  Appointment of Sir James Chadwick as Rutherford Lecturer for 1953, 290
  Lectures for 1953, 290
  New Fellows of the, 546
  The Transliteration of Russian, Serbian and Bulgarian for Bibliographical Purposes, 548
  Election of Foreign Members, 775, 864, 956, 1002
  Discussion on the Function and Location of Enzymes in Cells, 815
  Discussion on the Floor of the Atlantic Ocean, 857
  Appointment of A. S. Laughton as John Murray Travelling Student in Oceanography and Limnology, 959
  Depository of Unpublished Mathematical Tables, 1140
Royal Society of Arts : Albert Medal for 1953 awarded to Dr. E. D. Adrian, 1005
Royal Society of Edinburgh : Offer of a David Anderson-Berry Silver-Gilt Medal and Prize, 20
  Election of Fellows, 418
  Gunning Victoria Jubilee Prize for 1948–52 awarded to Prof. A. C. Aitken, 867
  Makdougall-Brisbane Prize for 1950–52 awarded to Prof. E. M. Wright, 867
Royal Society of Medicine (Endocrinological Section), and the Society for Endocrinology : Symposium on the Thyroid Gland, 551
Royal Society of Medicine (Section of Pathology) . Symposium on Haemoglobin Metabolism, 464
Royal Society of New South Wales : James Cook Medal for 1952 awarded to Prof. W. L. Waterhouse, 678
Royal Society of South Africa : Election of Officers, 914
Royal Society Mond Laboratory, Cambridge (Dr. D. Shoenberg), 458
Royal Technical College, Glasgow : Appointment of Dr. D. C. Pack to the chair of mathematics, 287
  Report on Research during the Session 1951–52, 822
Rozsa, G., and Spicer, S. S. : Nature of Heinz Bodies, 84
Rubber Producers' Association, British : Appointment of Dr. L. C. Bateman as director of research, 1098
Rubinstein, Kurt (Kjær, Dr. Anders, and) : Paper Chromatography of Thioureas, 840
Ruddock, Prof. F. A. : *Obituary* of Prof. J. S. S. Brame, 286
Rudge, A. J. (Banks, A. A., and) : Selenium Hexafluoride—Dielectric Strength and some Chemical Properties, 390
Rudstam, Gosta, and Svedberg, Prof. The : Use of Tracers in Chemical Dosimetry, 648
Ruff, G. H. : Appointed director of grain storage, Tanganyika, 421
Rumford, a Bicentenary (Thomas Martin), 538
Rumford as a Scientist (Sir Eric Rideal), 540
Rumford, Count : Benjamin Thompson, *review* by T. Martin, 947
Runciman, W. A. : Numerical Methods and Automatic Computing in Atomic Theory, 869
Rural Life at Home and Overseas, Institute of, and others : Course on The Countryside, a Medium for Teaching, 549
Ruse, Prof. H. S. : The Ricci Calculus, 61
Rushbrooke, Prof. G. S. : Elasticity in Liquids, 778
Rushby, G. G. : Appointed deputy game warden, Tanganyika, 421
Russell, Archibald G. B. : Tradition and the Coronation, 948
Russell, Dr. E. W. : The Problem of Future World Food Supply, 161
Russell, P. S. : Oceanography in the United States, 71
  Fisheries Research in British Colonies, 159
Russell, Sir John : *Obituary* of Dr. J. Henderson Smith, 16
  India's Food Problems, *review*, 1038
  Elected a Foreign Member of the Finnish Academy of Science and Letters, 1054
Russell, Margaret P. (Bonser, Dr. Wilfrid, and) : Cost of German Medical and Scientific Periodicals, 403
Russian Institute of Scientific Information : Establishment of, 504
Ruston, Dr. A. F. : Appointed senior lecturer in pure mathematics at the University of Sheffield, 959
Rutgers, Prof. A. J., and Nagels, P. : Centrifugation Potentials in Sols of Silver Iodide, 568
Rutherford, Dr. D. E. : Classical Mechanics, *review* by Prof. H. T. H. Piaggio, 992
Ruyssen, R. (Cross, Dr. R., and) : Adsorption and Haemolytic Action of Diacetyldeoxycholate, 846
Ryan, Dr. Francis J. : Competitive Suppression of Prototrophs, 400
Rycroft, B. W. : Preservation of Normal Tissues for Transplantation, 1049
Ryhming, Miss I. : Human Performance, 961
Ryley, J. F. : Carbohydrate Metabolism in Protozoa and Metal-binding Substances, 747
Rzoska, Dr. J. : Hydrobiology and Inland Fisheries of Africa, 291

SACK, Dr. R. A. : Mean Square Radius of randomly coiled Molecular Chains, 310
Saha, Dr. N. N. (Astbury, Prof. W. T., and) : Structure of Algal Flagella, 280
Salisbury, Sir Edward : Garden Flora of Hardy Plants in France, *review*, 493
  Management and Conservation of Vegetation in Africa, *review*, 496
  A Manual on the Weeds of the Major Crops of Ceylon, *review*, 587
Salt, F. E. : Production and Utilization of Petroleum Raw Materials in the U.K. Chemical Industry, 680
Salter, Sir Arthur, and others : Parliament, a Survey, 183
Salter, P. J. (Hudson, J. P., and) : Effects of Different Water-regimes on the Growth of Tomatoes under Glass, 480
Sampford, M. R. : Statistical Method in Transport Management, 251
Sampson, Prof. Arthur W. : Range Management, Principles and Practices, *review*, 97
Sampson, H. C. : *Obituary* by Sir Geoffrey Evans, 16
Samson, H. R. : Clay–Water Relationships, 682
Sanders, Dr. F. K. : Preservation of Normal Tissues for Transplantation, 1049
Sandison, A. : Appointed deputy director of the National Institute of Agricultural Botany, 111
Sandler, Dr. Joseph, and others : Social Psychiatry, *review* by Dr. Clifford Allen, 667
Sandys, Duncan : Atomic Energy for Industrial Power and other Uses, 287
  Increased Expenditure for Research and Development by the Ministry of Supply, 288
Sanford, G. B. : Persistence of *Rhizoctonia solani* in Soil, 331
Sanger, Dr. F. : A Disulphide Interchange Reaction, 1025
Sanger, Dr. Ruth, and others . A New Blood-Group Antibody, Anti-$Jk^b$, 431
Sanitary Institute, Royal : Appointment of P. Arthur Wells as secretary, 20
  Annual Health Congress, 244
Sanitary Institute, Royal, in collaboration with the Infestation Control Division of the Ministry of Agriculture and Fisheries : Rodent Control Exhibition, 867
Sansom, H., and others : Reports on Experiments at Kongwa on Artificial Control of Rainfall, 829
Santen, Dr. J. H. van : Luminescence and Ferroelectricity, 1056
Sarabhai, V., and others : Daily Variation of Meson Intensity and its Possible Solar Origin, 122
Sarachek, A. (Lucke, W. H., and) : X-Ray Inactivation of Polyploid Saccharomyces, 1014
Sarjant, Prof. R. J. : Resignation from the chair of fuel technology in the University of Sheffield, 819 ; work of, 819
Sarton, Prof. George : A Guide to the History of Science, *review*, 807
  A History of Science, Ancient Science through the Golden Age of Greece, *review*, 807
Saunders, J. T. : Appointed principal of University College, Ibadan, 959
Saunders, P. R. : Properties of Gelatin Fractions, 1100
Saxena, A. P., and others : Langmuir Adsorption as a Determinant of Conductivity in a Low-frequency Electric Discharge, 929
Saxov, S. : Geophysical Prospecting, 202
Scadding, Dr. J. G. : Prevention of Tuberculosis, *review*, 626
Schaeffer, B., and others : The Problem of Land Connections across the South Atlantic, with special reference to the Mesozoic, 669
Schenck, Dr. James . Activation of Lithium Iodide by Europium, 518
Schepers, J., and others : Measurements on Superconductivity in Thin Tin Films, 834
Schinckel, P. G. : Follicle Development in the Australian Merino, 310

# TITLE INDEX

A IS Happy—B is Not'?, review by W L Sumner, 97
Aberdeen Depopulation and Rural Life in (Bertram Hutchinson), 643
Ablett Prize for 1952 of the Iron and Steel Institute awarded jointly to Dr S. A. Burke and G. A. Sparham, 506
Abnormalities in the Ionosphere at High Latitudes (W. R. Piggott), 124
Abomasal Mucosa of the Sheep Development of *Ostertagia circumcincta* in the (R. I. Sommerville), 482
Absorption of Glucose from the Intestine Active (S. Hestrin-Lerner and Prof. B. Shapiro), 745
Absorption of Polymyxin by Bacteria (Dr. A V. Few and Dr. J. H Schulman), 644
Absorption of Water by the Egg of the Garden Chafer, *Phyllopertha horticola* L. (Roger Laughlin), 577
Absorption Spectra of the Ethyl Chlorophyllides (W. F. Watson), 842
Abstracting and Library Work in the U.S.S.R (W. G. Cass), 555
Academic Freedom and the Unorthodox, 663
Accelerating Effect of an Extract of Vernalized Embryos of Winter Rye on Flower Initiation in Unvernalized Embryos (O. N. Purvis and Prof. F G. Gregory), 687
Acceleration of Heavy Ions to High Energies (Dr. D. Walker and Dr. J. H. Fremlin), 189
Accelerator · A Heavy-Particle (J. W Gallop), 306
  Travelling-Wave Linear, for X-Ray Therapy (C. W. Miller), 297
Accelerator (Proton Linear) · A New Focusing Principle applied to the (J S. Bell), 167
Acetaldehyde at High Intensity Limiting Products in the Photolysis of (M. A. Khan, Prof. R. G W. Norrish and Dr. G. Porter), 513
Acetic Acid in Fresh Grass (Dr A. J. G. Barnett and R. E B Duncan), 478
Acetoacetate . Effect of, on Glycogen Synthesis and Glucose Utilization in the Isolated Rat Diaphragm (A. Chain and E Wertheimer), 44
  Effect of, on the Succinic Acid Oxidase System (Prof M. C. Nath and V G. Hatwalne), 1158
  Enzymatic Breakdown and Synthesis of (Dr. Joseph R. Stern, Dr Minor J. Coon and Miss Alice Del Campillo), 28
2-Acetylaminofluorene . Rapid Production of Malignant Hepatomas by Simultaneous Administration of Tannic Acid and (Dr. Martha Mosonyi and Dr. Béla Korpássy), 791
Acetylations (Biological) : Narcotics and (W. J. Johnson and Prof. J. H. Quastel), 602
Acetylcholine from Brain Tissue . Extraction of (J. Crossland and A. J. Merrick), 267
Acids Anaerobic Growth of *Escherichia coli* in the Presence of certain (G. A. Morrison), 937
Acids (Fatty) · Role of Choline in the Oxidation of, by the Isolated Liver (Camillo Artom), 347
Acids (Rape-oil Fatty) . Urea Complexes of (J. H. Skellon and C. G. Taylor), 266
Acoustical Designing in Architecture (Prof. Vern O. Knudsen and Dr. Cyril M. Harris), *review*, 54
Acoustics : Aeronautical, and Jet Noise in particular (Acoustics Group of the Physical Society and the Royal Aeronautical Society Discussion on), 914
  An Introduction to (Prof Robert H. Randall), *review*, 142
  International Congress of, 332
  The Teaching of (Acoustics Group of the Physical Society and the Education Group of the Institute of Physics Discussion on), 21
Acrasin Aggregation in Cellular Slime Moulds—*in vitro* Isolation of (B. M. Shaffer), 975
Acrylonitrile in the Diels–Alder Reaction : Relative Reactivities of the Olefinic and Cyano Links of (Prof. G. J. Janz and N E Duncan), 933
ACTH : Relation of Adrenocorticotrophin, to the Melanophore Expanding (B) Hormone of the Pituitary (Prof. H. Waring and B. Ketterer), 862
Actin : Action of Cortisone on the Polymerization of (J B Cowie and Prof. R. H. Thorp), 1067
Action : Springs of (Present Question Conference on), 867
Action Potential from the Motor Nerves of the Jellyfish *Aurelia aurita* Lamarck. (Adrian Horridge), 400
Activation of Enzymes by Chelating Agents (S. H. Altmann and Dr. E M. Crook), 76
Activation of Lithium Iodide by Europium (Dr. James Schenck), 518
Activation of Lysozyme . Inhibition and (Dr. E. Kaiser), 607
Activity Data and the Association of Hydrogen Chloride in Concentrated Solutions (A. M. Posner), 519
Acyl Derivatives Estimation of the 9 10-Dihydroxystearic Acids and their (Dr. G. King), 566
*Adamsia rondeletii* Purple Pigment and Protein in the Threads of the Sea Anemone (Prof. Anast. Christomanos), 886
Adaptation to Galactose in *Saccharomyces cerevisiae* · Relationship between the Oxidative and Fermentative Phases during (Dr. A. Leonard Sheffner), 1073
Addition and Substitution Laws of, in Atomic Reactions of Halogens (Jean Adam, P. A. Gosselain and Prof. P. Goldfinger), 704
Adelie Penguin (Dr. W. J L. Sladen), 952
Adenine Formation of Adenine Nucleotides from, by Pigeon Liver Homogenates (Eugene Goldwasser), 126
Adenine Nucleotides · Formation of, from Adenine by Pigeon Liver Homogenates (Eugene Goldwasser), 126
Adenohypophysis and the Hypothalamus · Functional Relations of the (A. P D. Thomson and Prof. S Zuckerman), 970
Adenosine Triphosphate catalysed by Lobster Muscle Mechanism of Hydrolysis of (Edith Clarke and D. E. Koshland, jun.), 1023
Adrenal Cortex of the Rat · Nerve Fibres in the (J. D. Lever), 882
Adrenal Cortical Steroids and their Metabolites The Determination of (Society for Endocrinology Symposium on), 777
Adrenalin and Noradrenalin in the Human Foetal Adrenals and Aortic Bodies Determination of (Kalevi Niemineva and Aimo Pekkarinen), 436
Adrenalin and Noradrenalin from the Suprarenal Medulla · Influence of the Blood Glucose-Level on the Secretion of (Hans Dunér), 481
Adrenaline Detection of some Precursors of, by Paper Chromatography (D. M Shepherd and Dr. G. B. West), 1160
Adrenals and Aortic Bodies (Human Foetal) : Determination of Adrenalin and Noradrenalin in the (Kalevi Niemineva and Aimo Pekkarinen), 436
Adrenocorticotrophin (ACTH) . Relation of, to the Melanophore Expanding (B) Hormone of the Pituitary (Prof. H. Waring and B. Ketterer), 862
Adsorbed Molecules : Measurement of Activated Diffusion of (R. A. W. Haul), 519
Adsorption of DDT on Suspended Solids in River Water and its Role in Black-fly Control (F. J. H. Fredeen, A. P. Arnason and B. Berck), 700
Adsorption and Hæmolytic Action of Diacetyldeoxycholate (Dr. R Cross and R Ruyssen), 846
Aerial for Radio Astronomy · A High-Resolution (W. N. Christiansen), 831
Aerodynamic Techniques The Industrial Application of (National Physical Laboratory, Notes on Applied Science No. 2), 1097
Aeronautical Acoustics and Jet Noise in particular (Acoustics Group of the Physical Society and the Royal Aeronautical Society Discussion on), 914
Æsthetics and Cosmetology : Seventh International Congress of, 776
Affinity, a New Genetic Phenomenon in the House Mouse—Evidence from Distant Crosses (Donald Michie), 26 : Evidence from within Laboratory Stocks (Mrs. Margaret E. Wallace), 27
Africa · Education in, 1127
  Fossil Mammals of, No. 4, Miocene Anthracotheriidae from East Africa (D. G. MacInnes), 505 ; No. 5, The Miocene Lemuroids of East Africa (Prof. W. E. Le Gros Clark and D. P. Thomas), 505
  Hydrobiology and Inland Fisheries of (Scientific Council for Africa South of the Sahara Symposium on), 291
  Management and Conservation of Vegetation in, *review* by Sir Edward Salisbury, 496
  Prehistory in, *review* by Miles Burkitt, 231
  Problems of Distribution of Animals and Plants in (Linnean Society of London Discussion on), 639
Africa (East) . Miocene Anthracotheriidae from (D G. MacInnes), 505
  Miocene Lemuroids of (Prof W. E. Le Gros Clark and D. P. Thomas), 505
  Occurrence of *Puccinia polysora* Underw. in (R. M. Nattrass), 527
Africa (South-West) : Absence of the Sickle Cell Trait in the Bushmen of (S. B Griffiths), 577
Africa South of the Sahara · Sociological Research in (Meeting of the Scientific Council for Africa South of the Sahara to consider), 246
African Education . Stock-taking on (Olumbe Bassir), 1134
African Education, a Study of Educational Policy and Practice in British Tropical Africa (produced on behalf of the Nuffield Foundation and the Colonial Office), 1127, 1134
African Inland Waters : Sulphates in (R. S. A. Beauchamp), 769
African Olive Colobus Monkey, *Procolobus verus* (W. C. Osman Hill), 18
African Red-tailed Monkey, *Cercopithecus ascanius schmidti* (Dr. A J. Haddow), 18
African (South) Bantu . Serum Iron and Iron-binding Capacity in the (Th. Gerritsen and A. R P. Walker), 699
African (South) Waters The Shark, *Isurus oxyrinchus*, in (Prof. J. L. B. Smith), 977
Africans · Serum Proteins in (M W. Stanier), 880
'After-effect' in Aqueous Solutions of Deoxyribonucleic Acid irradiated with X-Rays (Malcolm Daniels, Dr. George Scholes and Dr. Joseph Weiss), 1153
Age and Evolution of the ζ Persei Group of *O*- and *B*-Type Stars (A. Blaauw), 1005
Ageing : Some Social and Psychological Problems of (British Association for the Advancement of Science, Section J (Psychology), Discussion on), 422
Agglutinin Linkage · Nature of (Colonel G W. G. Bird), 748
Aggregation in Cellular Slime Moulds—*in vitro* Isolation of Acrasin (B. M. Shaffer), 975
Agricultural Census in Iraq (Dr. K. G. Fenelon), 821
Agricultural Development (Colonial) : Insecticides and (Colston Research Society Symposium on), 824
Agricultural Machinery A Survey of the Trade in (Commonwealth Economic Committee), 199
Agricultural Research Careers in (Agricultural Research Council), 330
Agricultural and Forestry Research Stations in the British Commonwealth, 1952 . Gazetteer of, *review* by H. G. C , 54
Agriculture American (A. N. Duckham), 374
Agriculture (Dutch) · Water Problems in, 19
Agriculture in the University of Sydney, 594
Agronomy : Advances in, Vol. 3 (edited by A G. Norman), *review*, 946
Aircraft at Supersonic Speeds · Noise from (C. H. E. Warren), 214 ; (E. W. Bastin), 215 ; (P. Rothwell), 215 , (Dr. E. Esclangon), 827
Air-Liner . The 'Comet' (C. T Wilkins), 249
Albert Medal of the Royal Society of Arts for 1953 awarded to Dr. E. D. Adrian, 1005
Albumin (Bovine Serum) Organic Anion Binding by Denatured (Dr. L. L. Uzman), 653
Aldohexoses : A Biophysical Test for (W Lindquist), 393
Alga *Chlorella* . Demonstration of Transaminase Systems in the (J. W. Millbank), 476
Alga *Spongomorpha* (Marine) Variability in the X-Ray Diagram of the Cell Walls of the (E. Nicolai and Dr. R. D. Preston), 752
Alga (Red) Studies of a (Dr. K. M. Drew), 331

Algæ (Green): Number of Fibrils in the Cilia of the (Prof. I. Manton), 485
Algal Flagella: Structure of (Prof. W. T. Astbury and Dr. N. N. Saha), 280
Alkali: Artefacts produced from 3-Iodo-Tyrosine and 3 : 5-Di-Iodo-Tyrosine by Heating with (P. G. Stanley), 933
Alkali Metals: Resonance Radiation from Hydrogen Flames containing (C. G. James and Dr. T. M. Sugden), 428
Alkaloid Protopine: Origin of the Methylenedioxy Groups of the (M. Sribney and Prof. S. Kirkwood), 931
Alkaloids (Tropane): Conformation of (Dr. Ajay K. Bose and Dilip K. Roy Chaudhuri), 652
Alkaloids of *Aspidosperma oblongum* A.DC.: Pharmacology of the (J. N. Banerjee and J. J. Lewis), 802
Alkaloids of *Datura innoxia* (W. C. Evans and Dr. M. W. Partridge), 656
Alkyl Groups in Nucleophilic Substitution: Effects of (C. W. L. Bevan, Prof. E. D. Hughes and Prof. C. K. Ingold), 301
Alloy (Aluminium–Copper): Exudation of Material from Slip Bands at the Surface of Fatigued Crystals of an (P. J. E. Forsyth), 172
Alloys (Magnesium–Lithium β-Phase): Structure of (R. L. P. Berry and Prof. G. V. Raynor), 1078
Alloys (Non-Ferrous Metals and): The Cold Working of (Institute of Metals Symposium on Metallurgical Aspects of), *review* by Dr. A. J. Kennedy, 992
Alpha-Particles in Thin Films: Radiation Induced by (Amos Norman, M. A. Greenfield and Paul M. Kratz), 487
α-Track Autoradiographs of Biological Specimens: Improved (Dr. Hilde Levi), 123
A.C. Operation of Ion Chambers (Dr. A. H. Ward), 837
Alternative Soft Fibres to Jute, *review* by Sir Geoffrey Evans, 535
Aluminium (Anodized): Effects of Water Vapour on the Electrical Properties of (Dr. F. Ansbacher and Dr. A. C. Jason), 177
Aluminium Scheme: Volta River, 405
Aluminium Succinate in *Cardwellia sublimis* F. Muell: An Occurrence of (L. J. Webb), 656
Aluminium–Copper Alloy: Exudation of Material from Slip Bands at the Surface of Fatigued Crystals of (P. J. E. Forsyth), 172
'Amberlite IRA 400 (OH′)': Degradation of Sugars on Ion-Exchange Columns of (J. D. Phillips and Dr. A. Pollard), 41
America (Eastern North): Cytology of the *Dryopteris spinulosa* Complex in (Prof. I. Manton and S. Walker), 1116
America (Latin): Bibliography of Science in, 109
  Scientific Institutions and Scientists in (Ecuador, Vol. 1), 110; (Argentina, Vol. 3), 110
  Social Anthropological Studies of, 686
America and Polynesia: Prehistoric, *review* by Prof. Raymond Firth, 713
American in Europe, the Life of Benjamin Thompson, Count Rumford (Egon Larsen), *review* by T. Martin, 947
American Agriculture (A. N. Duckham), 374
American Chemical Society, 1876–1951, *review* by Sir Eric Rideal, 536
American Enterprise: Du Pont, the Autobiography of an, *review*, 993
American Eyes: The Sterling Area in, *review* by Mrs. Ursula K. Hicks, 537
American Indians in the Pacific (Thor Heyerdahl), *review* by Prof. Raymond Firth, 713
American-Asian Floristic Relationships (Hui-Lin Li), 206
Amine Oxidase in Liver: Histochemical Demonstration of (C. M. Francis), 701
Amino-Acids: Inhibition of *E. coli* Strains by (D. Rowley), 80
Amino Acids of Nisin: Sulphur-containing (G. G. F. Newton, Dr. E. P. Abraham and Dr. N. F. Berridge), 606
Amino-Acids and Proteins (compiled and edited by Prof. David M. Greenberg), *review* by Dr. C. H. Bamford, 765
*Amoeba discoides* recorded for Milngavie, Dumbartonshire (Sister Monica Taylor), 225
*Amoeba proteus*: A Biological Agent for securing Large Numbers of (Sister Monica Taylor), 704
  Effect of Thyroid Gland on the Cultivation of (Sister Monica Taylor), 313
Amorphous and Crystalline Chain Orientation in Polythene Film: Crossed (D. R. Holmes, R. G. Miller, R. P. Palmer and C. W. Bunn), 1104
Amphibian Blood Circulation: A Cinematographic Technique, using Ultra-violet Illumination, for (J. R. Simons and Dr. A. R. Michaelis), 801; (G. E. H. Foxon), 801
Amyl Acetate Vapour emanating from Marking Paint: Reversal of Phototaxis in Prepupae of Hymenoptera (Tenthredinidae) caused by (Dr. F. L. Waterhouse), 438
Anaerobes on English Flax: Sporulating (Esther Hellinger), 1119
Anaerobic Growth of *Escherichia coli* in the Presence of certain Acids (G. A. Morrison), 937
Anaesthetic Action: Synthesis of Quaternary Compounds possessing Lasting Local (Dr. K. Nádor, F. Herr, Gy. Pataky and J. Borsy), 788
Anaesthetic Properties: Quaternary Derivatives of Benzoyltropine and Benzoyl-ψ-tropine with Anticholinergic and Local (Dr. László Gyermek), 788
Analog Computers: Electronic (D–C Analog Computers), (Dr. Granino A. Korn and Theresa M. Korn), *review* by Dr. M. V. Wilkes, 1132
Analogue Computers: D.C., *review* by Dr. M. V. Wilkes, 1132
Analysis: Semimicro Qualitative (Prof. Paul Arthur and Prof. Otto M. Smith), third edition, *review* by Dr. J. A. Mair, 1133
Analysis (Differential Thermal): Bibliography of (Prof. W. J. Smothers, Y. Chiang and A. Wilson), 244
Analysis (Proximate and Functional): Second Symposium on, 776
Analysis of the Directivity of Solar Radio Emission from Sunspots: A Method of (T. Takakura), 445
Analysis of Urinary Steroids: Fluorometric (Dr. M. Finkelstein), 254
Anastomosis of the Hepatic Artery and Hepatic Vein within the Mammalian Liver: Anatomical and Physiological Evidence of (Dr. W. H. Horner Andrews and Prof. B. G. Maegraith), 222
Anatomical and Physiological Evidence of Anastomosis of the Hepatic Artery and Hepatic Vein within the Mammalian Liver (Dr. W. H. Horner Andrews and Prof. B. G. Maegraith), 222
Anatomy of Chromosomes, *review* by Dr. C. D. Darlington, 139
Anderson-Berry Silver-Gilt Medal and Prize of the Royal Society of Edinburgh, 20
Angiosperm Inflorescence Apex: Structure of the (Dr. John G. Vaughan and F. R. Jones), 751
Angiosperms: Plant Morphology and Plant Taxonomy—(G. Erdtman), *review* by Dr. W. B. Turrill, 362
Angle of Arrival of Z Echoes (G. R. Ellis), 258
Angler's Entomology: An (J. R. Harris), *review* by Prof. J. W. Munro, 320
Anglo-Saxon Magic and Medicine (J. H. G. Grattan and Charles Singer), *review* by Dr. Douglas Guthrie, 140
Anhydrides: Hydrolysis of, by Esterases (Prof. Felix Bergmann, Menachem Wurzel and Arela Shimoni), 744
Animal Breeding: Plant and (Joint Biology Committee and the Association of Agriculture Conference on), 110
Animal Geography: Ecological (Prof. W. C. Allee and Karl P. Schmidt), second edition, *review* by Charles Elton, 761
Animal Physiology: Comparative (Prof. David W. Bishop, Prof. Frank A. Brown, Jr., Prof. Theodore L. Jahn, Prof. C. Ladd Prosser and Prof. Verner J. Wulff), *review* by Prof. W. Burns, 363
Animal Ways: King Solomon's Ring, New Light on (Konrad Z. Lorenz), translated from the German by Marjorie Kerr Wilson, *review* by T. H. H., 1133
Animals: Cooperation among (Prof. W. C. Allee), *review* by Dr. W. H. Thorpe, 453
  Polyploidy in (Dr. C. D. Darlington), 191
  Synthesis of L-Ascorbic Acid in Plants and (Dr. F. A. Isherwood, Mrs. Y. T. Chen and Dr. L. W. Mapson), 348
Animals (Laboratory): The Supply of (Laboratory Animals Bureau Discussion on), 334
Animals (Marine): A New Technique for Microscopic Preparations of small (Jessie J. Rankin), 35
Animals (Small): An Olfactometer for observing the Behaviour of (Prof. G. C. Varley and Roy L. Edwards), 789
Animals (Wild): Birds and, including Marine Mammals (H. Trevor Jones), *review* by T. H. H., 143
Animals and Plants in Africa: Problems of Distribution of (Linnean Society of London Discussion on), 639
Anion Binding: Organic, by Denatured Bovine Serum Albumin (Dr. L. L. Uzman), 653
Anion-Exchange Resins and Solutions containing Sugars: An Action of Strongly Basic (Dr. A. C. Hulme), 610
*Anopheles claviger*, *quadrimaculatus* and *aquasalis*: Extension of the Salivary Chromosome Method to (Dr. G. Frizzi), 1072
Anthracene: Polarized Ultra-Violet Absorption of (Dr. D. P. Craig and P. C. Hobbins), 566
Anthracotheriidae: Miocene, from East Africa (D. G. MacInnes), 505
Anthrone: Interference of Pentose in the Estimation of Hexose Sugars with (R. Johanson), 176
Anthropological Studies: Social, of Latin America, 686
Anthropology (Palaeo-): A Classic of, *review* by Prof. W. E. Le Gros Clark, 361
Anti-D Sera separated by Paper Electrophoresis: Serological Activity of Globulin Fractions of (Branislav D. Janković and Herman W. Krijnen), 982
Antibiotics: Action of, on Avian Tubercle Bacilli studied with the Electron Microscope (E. M. Brieger, Dr. V. E. Cosslett and Audrey M. Glauert), 211
  Applications of Electrophoresis in studying New (N. Kelso King and Hazel M. Doery), 878
Antibiotics, their Production and Uses in Industry (Society for Applied Bacteriology Symposium on), 914
Antibody, Anti-$Be^a$: A New Blood-Group (Dr. Gertrude Plaut, Elizabeth W. Ikin, Dr. A. E. Mourant, Dr. Ruth Sanger and Dr. R. R. Race), 431
Anticholinergic and Local Anaesthetic Properties: Quaternary Derivatives of Benzoyltropine and Benzoyl-ψ-tropine with (Dr. László Gyermek), 788
Anti-cholinesterase Drugs: Bibliography on Cholinesterases and the (Dr. K.-B. Augustinsson), 729
Anti-diuretic and Oxytocic Substances liberated by the Digestion of Plasmatic Proteins with Pepsin (Prof. H. Croxatto, L. Barnafi, G. Rojas, A. Reyes and A. Infante), 82
Anti-Fouling Research: Gregariousness in Barnacles in relation to the Fouling of Ships and to (Dr. E. W. Knight-Jones and Dr. D. J. Crisp), 1109
Antifungal Substance of Fungal Origin: A New (P. Delmotte and J. Delmotte-Plaquee), 344
Antigen devoid of Ribonucleic Acid: Occurrence in Plants Infected with Tobacco Mosaic Virus of a Crystallizable (Prof. R. Jeener and P. Lemoine), 935
Antigenic Structure in Bacteria: Some Relationships between Morphology and (Dr. K. A. Bisset), 1118
Antiquities: Hawaiian (Moolelo Hawaii), (David Malo), translated from the Hawaiian by Dr. Nathaniel B. Emerson, second edition, *review* by Dr. G. H. S. Bushnell, 764
Antiquities (Egyptian): Flinders Petrie Collection of (Exhibition in the Museum of Egyptology, University College, London), 914
Antitumorigenic Corticoids: Structural Features of (Dr. Elvira Mardones, Dr. Rigoberto Iglesias and Prof. A. Lipschutz), 1026
Aortic Bodies: Determination of Adrenalin and Noradrenalin in the Human Foetal Adrenals and (Kalevi Niemineva and Aimo Pekkarinen), 436
Aphid Genus *Periphyllus* (Prof. E. O. Essig and Frieda Abernathy), *review* by J. P. Doncaster, 765
Aphids: Infectivity of, after Several Hours on Tobacco Infected with Potato Virus Y (Dr. R. H. E. Bradley), 755
  A Method of obtaining Phloem Sap via the Mouth-parts of (Dr. J. S. Kennedy and T. E. Mittler), 528
Apiculus Colour: A Gene for Photoperiod Sensitivity in Rice linked with (Dr. M. P. Chandraratna), 1162
Apple Trees: Nitrogen Metabolism of (E. G. Bollard), 571
*Applied Microbiology*, No. 1 (Society of American Bacteriologists), 638
*Aptenodytes forsteri*: Embryology of the Emperor Penguin (T. W. Glenister), 357
Aqueous Solution: Molecular Configuration of Dextrans in (Dr. A. G. Ogston and E. F. Woods), 221
Aqueous Solutions of Deoxyribonucleic Acid Irradiated with X-Rays: 'After-effect' in (Malcolm Daniels, Dr. Gerald Scholes and Dr. Joseph Weiss), 1153

Aqueous Solutions of Inorganic Salts: Specific Volume of Cellulose in (Dr. S. M. Neale and G. R. Williamson), 842
Aqueous Stains: Permeability of Insect Cuticle to, and Vulnerability to Insecticides (S. Mukerji and S. N. Chatterjee), 119
Aqueous Systems: Formation of Labile Phosphate Esters by Irradiation of Nucleic Acids with X-Rays in (Dr. George Scholes and Dr. Joseph Weiss), 920
Arabinose and Xylose in Jute: Association of Glucose, (Dr. D. B. Das, M. K. Mitra and J. F. Wareham), 613
Archæological Excavations in the Hotu Cave, Iran (C. S. Coon), 821; (Louis B. Dupree), 821; (J. L. Angel), 821
Archæology: Gods, Graves and Scholars, the Story of (C. W. Ceram), translated from the German by E. B. Garside, *review* by M. C. Burkitt, 765
Arches in the Solar Corona: A Theoretical Model for (Dr. J. W. Dungey), 618
Architecture: Acoustical Designing in (Prof. Vern O. Knudsen and Dr. Cyril M. Harris), *review*, 54
Arithmetic: The Higher (Prof. H. Davenport), *review*, 233
Aromatic Compounds: Graphitic Acid from, by Peroxide Treatment (G. A. Bottomley and J. G. Blackman), 620
  Optical Exaltation in (D. W. van Krevelen, L. Blom and H. A. G. Chermin), 1075
Aromatic N-Glucosides: Transglucosylation of (Prof. R. Bognár and P. Nánási), 475
Aromatic Nucleus: Simultaneous Sulphonation and Nitration in an (A. Bryson and J. L. Garnett), 41
Arsenic-71: Beta-Spectrum of (Hugo Atterling and Sigvard Thulin), 927
Art and Technics (Lewis Mumford), 359
Art Gallery: Scientific Method and the (F. I. G. Rawlins and Dr. A. E. Werner), 199
Artefacts produced from 3-Iodo-Tyrosine and 3:5-Di-Iodo-Tyrosine by Heating with Alkali (P. G. Stanley), 933
Arterio-Venous Oxygen and Carbon Dioxide Differences across the Kidney: Effect of Nervous Stimulation on the (Dr. Joseph H. Cort), 784
Arthropods (Soil): Effects of DDT and BHC on (J. G. Sheals), 978
Artificial Control of Rainfall: Reports on Experiments at Kongwa on (D. A. Davies, D. Hepburn and H. Sansom), 829
Asci of Yeast: Genetic Analysis of Intact Incomplete (E. A. Bevan), 576
Ascites Tumours: Conversion of Solid into (Dr. George Klein), 398
L-Ascorbic Acid in Plants and Animals: Synthesis of (Dr. F. A. Isherwood, Mrs. Y. T. Chen and Dr. L. W. Mapson), 348
Ash Pictures (Prof. Gosta Edman), 1008
Ashby Curves: Red-Cell Survival and (Robert L. Evans and D. S. Amatuzio), 798
Ashes (Plant): Microscopy of (Dr. J. W. Fairbairn), 1008
Asia (South): Bibliography of Scientific Publications of (South Asia Science Co-operation Office), No. 6, July–December 1951, 246
Asia (South and South-East): Technical Assistance to, 956
Asparagine: Structure of (Dr. S. J. Leach and Dr. H. Lindley), 1062; (Prof. F. C. Steward and Dr. J. F. Thompson), 1063
Asparagine in Blood Plasma (J. M. Barry), 1123
'*Aspergillus niger* β-Glucosidase': Relative Specificity of the Chemically Modified (Dr. Yutaka Murakami), 522
*Aspidosperma oblongum* A.DC: Pharmacology of the Alkaloids of (J. N. Banerjee and J. J. Lewis), 802
*Asterias rubens*: Protoporphyrin in the Integument of (G. Y. Kennedy and Dr. H. G. Vevers), 81
A.S.T.M. Index of X-Ray Powder Diffraction Data (American Society for Testing Materials), 155
Astronomer (Amateur): Photography and the (Dr. G. Merton), 244
Astronomy: School (N. G. Matthew), 779
Astronomy at Geneva, 331
Atlantic (North): British Dependencies in the Caribbean and, 1939–1952 (Colonial Office), 380
Atlantic (South): The—Land Bridges or Continental Drift? (Prof. Arthur Holmes), 669
  The Problem of Land Connections across the, with special reference to the Mesozoic (E. Mayr, M. Ewing, W. H. Bucher, K. E. Caster, C. O. Dunbar, M. Kay, G. G. Simpson, D. I. Axelrod, T. Just, W. H. Camp, P. J. Darlington, jun., A. E. Emerson, B. Schaeffer, D. H. Dunkle, E. H. Colbert and A. S. Romer), 669
  The Role of the, in Biogeography and Evolution (Society for the Study of Evolution Symposium on, Proceedings), 669
Atlantic Ocean: The Floor of the (Royal Society Discussion on), 857
Atmosphere (High): Physics of the (British Association for the Advancement of Science, Section A (Physics and Mathematics), Discussion on), 146
Atmosphere (Lower): Scattering of 56-Mc./s. Radio Waves from the (P. A. Forsyth, Prof. B. W. Currie and F. E. Vawter), 352
Atmosphere (Upper): Cosmic-Ray Intensity and the Temperature of the (Harald Trefall), 888
  Physics and Medicine of the (edited by Dr. Clayton S. White and Brig.-General Otis O. Benson, Jr.), *review* by Dr. K. E. Spells, 51
  Synoptic Rocket Observations of the (Dr. S. F. Singer), 1108
Atmospherics with Very Low-frequency Components (F. Hepburn and E. T. Pierce), 837
Atomic Energy: Electronic Instruments in (Course at the Isotope School of the Atomic Energy Research Establishment), 290
  International Bibliography on (United Nations Atomic Energy Section of the Department of Security Council Affairs), 1003
Atomic Energy for Industrial Power and other Uses (Hector Hughes), 287; (Duncan Sandys), 287
Atomic Energy Establishments in Britain, 820
Atomic Energy Piles: Declassified Information on, 110
Atomic Energy Research in Britain, 820
Atomic Energy Research at Harwell, 205
Atomic Nuclei: Difference between the Density Distribution of Neutrons and Protons in (Prof. P. Gombás), 979, *erratum*, 1054
Atomic Power (Walter Isard and Vincent Whitney), 535
Atomic Reactions of Halogens: Laws of Addition and Substitution in (Jean Adam, P. A. Gosselain and Prof. P. Goldfinger), 704
Atomic Theory: Numerical Methods and Automatic Computing in (Symposium in the University Mathematical Laboratory, Cambridge), 868
*Aurelia aurita* Lamarck: An Action Potential from the Motor Nerves of the Jellyfish (Adrian Horridge), 430
Aureomycin in *Theileria parva* Infection (Dr. W. O. Neitz), 34
Aurora and Terrestrial Magnetic Storms: Radio Echoes observed during, using 35 and 74 Mc./s. Waves Simultaneously (Prof. L. Harang and B. Landmark), 1017
Austenite (Retained): An X-Ray Diffraction Study of the Transformation of, by Fracture (L. W. Pateman and H. S. Peiser), 696
Australia: Sir Joseph Banks, 'The Father of, *review* by Dr. Charles Singer, 449
Australian Merino: Follicle Development in the (P. G. Schinckel), 310
Autocrat of the Philosophers: Sir Joseph Banks, K.B., F.R.S., the (Dr. Hector Charles Cameron), *review* by Dr. Charles Singer, 449
Automatic Computing in Atomic Theory: Numerical Methods and (Symposium in the University Mathematical Laboratory, Cambridge), 868
Autonomy of Universities in Great Britain, 273
Autoradiographs: Improved α-Track, of Biological Specimens (Dr. Hilde Levi), 123
Auxin Precursors in Plants: Auxins and (Dr. Poul Larsen and Erik Bonde), 180
Auxins and Auxin Precursors in Plants (Dr. Poul Larsen and Erik Bonde), 180
Avian Tubercle Bacilli studied with the Electron Microscope: Action of Antibiotics on (E. M. Brieger, Dr. V. E. Cosslett and Audrey M. Glauert), 211
Aviation Medicine: Some Future Problems in, *review* by Dr. K. E. Spells, 51
Aymará et kičua: Bibliographie des langues (Paul Rivet et Georges de Créqui-Montfort), *review* by Dr. G. H. S. Bushnell, 1133
8-Azaguanine: Incorporation of, into Nucleic Acid of Tobacco Mosaic Virus (Dr. R. E. F. Matthews), 1065
Axon Formation in the Midbrain of the Chicken Embryo: Growth and (Dr. R. J. O'Connor), 131
*Azotobacter chroococcum*: Contamination of, by Gram-negative Bacterial Rods (Ernest A. Gray), 1163

BACK Grant of the Royal Geographical Society awarded to G. de Q. Robin, 636
Back-Mutation Tests with Mutants of *Neurospora*: Inhibition Effects in (C. M. Stevens and A. Mylroie), 179
Bacteria: Absorption of Polymyxin by (Dr. A. V. Few and Dr. J. H. Schulman), 644
  Chemical Constitution of the *L*-Forms of (Dr. Roger Vendrely and Prof. Robert Tulasne), 262
  Origin of Acquired Drug Resistance in (Prof. John Yudkin), 541
  Physiology of the Host-Parasite Relationship in Fungi and (Prof. W. Brown), 22
  Some Relationships between Morphology and Antigenic Structure in (Dr. K. A. Bisset), 1118
Bacteria (Catalase-negative): Susceptibility of, to Ultra-violet Irradiation (Sidney Mittler and John A. Laverty), 793
Bacteria (Sulphate-reducing): Cultivation of (Joy P. Grossman and Dr. John R. Postgate), 603
Bacteria on Microscope Slides: A New Method in Staining (Prof. P. H. H. Gray), 1030
Bacterial Degradation of Choline (B. P. Eddy), 573
Bacterial Fractions (Rumen): Encapsulation in (P. N. Hobson and Margaret J. MacPherson), 129
Bacterial Genetics: Terminology in (Prof. Boris Ephrussi, Dr. Urs Leopold, Dr. J. D. Watson and Prof. J. J. Weigle), 701
Bacterial Products: Fixation of, by Erythrocytes *in vivo* and by Leucocytes (Stephen V. Boyden), 402
Bacterial Reduction of Nitrate: Occurrence of Hydroxylamine in Lake Waters as an Intermediate in (Motoharu Tanaka), 1160
Bacterial Rods: Contamination of *Azotobacter chroococcum* by Gram-negative (Ernest A. Gray), 1163
Bacterial Viability Counts: A New Procedure for, and its Biophysical Applications (R. C. Valentine and Dr. J. R. G. Bradfield), 878
*Bacterium coli*: A Variant of (M. L. De, A. Guha and Dr. N. N. Das Gupta), 879
Bakerian Lecture for 1953 of the Royal Society (Prof. N. F. Mott), 290
Bang: The Supersonic (G. M. Lilley, R. Westley, A. H. Yates and J. R. Busing), 994
Bantu (South African): Serum Iron and Iron-binding Capacity in the (Th. Gerritsen and A. R. P. Walker), 699
Barium-Strontium-Calcium Triple Carbonate: Crystal Structure of (Jitsuo Terada), 517
Barnacles: Gregariousness in, in relation to the Fouling of Ships and to Anti-Fouling Research (Dr. E. W. Knight-Jones and Dr. D. J. Crisp), 1109
Barrier Layer Cells: Height of the Potential Layer in (M. S. Ridout), 219, *erratum*, 246
Basuto: The (Hugh Ashton), *review* by G. I. Jones, 142
Bay: The (Gilbert C. Klingel), *review*, 993
Bean Root Cells: Cytoplasmic Particles in (Dr. E. Robinson and R. Brown), 313; (G. L. Brown, S. Fitton Jackson and J. Chayen), 1113
Bearing Metals (Sleeve): Some Experiments with (Dr. Borge Lunn), 827
Bearing Properties of Metals: Testing of (Dr. D. Tabor), 827
Bee-eater: The Blue-cheeked (Miss Hilda M. Quick), 331
Beetle, *Potamodytes tuberosus*, Hinton: The Respiratory Bubble of the Aquatic (George A. Stride), 885
Beetle (Confused Flour): A Simple Method for Sexing the (J. A. Hope), 265
Behaviour (Insect): A Simple 'Response Balance' for studying (Dr. H. Hurst), 1120
Behaviour of Engineering Structures (Prof. A. J. S. Pippard), 766, 867
Behaviour of Small Animals: An Olfactometer for observing the (Prof. G. C. Varley and Roy L. Edwards), 789
Behaviour of Spider Crabs in the Presence of Octopuses (H. J. Boal), 887
Behaviour of the Swift: Breeding (David and Elizabeth Lack), 382
Beit Memorial Fellowships for Medical Research: Awards, 1097
Belgian Congo: Pedo-Botanical Surveys in the, 154
Belshahr, Iran: Archæological Excavations near, 821

Bengal System : Hydroponics, the (J. Sholto Douglas), *review* by Prof. R. H. Stoughton, 364
Benguela Current · Plankton of the (Dr. T. J. Hart), 631
  Upwelling in the (Ronald Currie), 497
Benzoyltropine and Benzoyl-ψ-tropine with Anticholinergic and Local Anæsthetic Properties : Quaternary Derivatives of (Dr. László Gyermek), 788
Benzoyl-ψ-tropine with Anticholinergic and Local Anæsthetic Properties : Quaternary Derivatives of Benzoyltropine and (Dr. László Gyermek), 788
Berkeley Symposium on Mathematical Statistics and Probability · Proceedings of the Second (edited by Jerzy Neyman), *review* by Prof. M. G. Kendall, 410, 463
Berseem (*Trifolium alexandrinum*) · Effect of Boron and Molybdenum Fertilizers on (N. P. Datta and H. Gurubasava Raj), 134
Bessel Functions of the First Kind of Orders Seventy-nine through One Hundred and Thirty-five : Tables of the (Staff of the Computation Laboratory of Harvard University), *review* by Prof. W. G. Bickley, 993
Bessemer Medal for 1953 of the Iron and Steel Institute awarded to R. Mather, 506
β-Forms of Fibrous Proteins and Synthetic Polypeptides (Dr. C. H. Bamford, L. Brown, Dr. A. Elliott, W. E. Hanby and I. F. Trotter), 1149
Beta-Irradiation on Mouse Epidermis : Latent Carcinogenic Action of (Dr. Philippe Shubik, A. Robert Goldfarb, A. C. Ritchie and Hermann Lisco), 934
Beta-Spectrum of Arsenic-71 (Hugo Atterling and Sigvard Thulin), 927
Beta-Spectrum of Radium E (J. Pniewski and M. Danysz), 694
BHC : Effects of DDT and, on Soil Arthropods (J. G. Sheals), 978
Bibliographical Purposes : The Transliteration of Russian, Serbian and Bulgarian for (Royal Society), 548
Bibliographie des langues aymará et kičua (Paul Rivet et Georges de Créqui-Montfort), *review* by Dr. G. H. S. Bushnell, 1133
Bibliography on Atomic Energy : International (United Nations Atomic Energy Section of the Department of Security Council Affairs), 1003
Bibliography on Cholinesterases and the Anti-cholinesterase Drugs (Dr. K.-B. Augustinsson), 729
Bibliography of Differential Thermal Analysis (Prof. W. J. Smothers, Y. Chiang and A. Wilson), 244
Bibliography of Geiger-Muller Counters (J. E. Walker), 677
Bibliography of Science in Latin America, 109
Bibliography of Scientific Publications of South Asia (South Asia Science Co-operation Office), No. 6, July–December 1951, 246
Bile Salts : Formation of Gall Stones—Physical Properties of (A. J. H. Rains and N. Crawford), 829
Biliverdin in Parasitic Cirripede Crustacea : Hæmoglobin and (Prof. H. Munro Fox), 162
Binucleate Cells in the Livers of Adult Rats . Percentage of (Marion F. Harrison), 611
Biochemistry : Careers in (Prof. G. F. Marrian), 780
Biochemistry of Phosphorus Compounds, *review* by Dr. T. Mann, 808
Biogeography and Evolution · The Role of the South Atlantic in (Society for the Study of Evolution Symposium on, Proceedings), 669
Biological Acetylations : Narcotics and (W. J. Johnson and Prof. J. H. Quastel), 602
Biological Activity of Insecticides Physical Factors in relation to (Crop Protection Panel of the Agriculture Group of the Society of Chemical Industry Discussion on), 869
Biological Agent for securing Large Numbers of *Amoeba proteus* (Sister Monica Taylor), 704
Biological Correlations : Variability of Internal Environment and the Mechanisms of (Eugène Schreider), 339
Biological Implications : Winter Cascading from an Oceanic Island and its (Brian P. Boden and Elizabeth M. Kampa), 426
Biological Research in Europe : Aid for (New York Zoological Society), 638
Biological Specimens : Improved α-Track Autoradiographs of (Dr. Hilde Levi), 123
Biological Students : Statistics for Medical and other (L. Bernstein and M. Weatherall), *review*, 278
Biological Systems Deformation and Flow in (edited by Prof. A. Frey-Wyssling), *review* by D. R. Wilkie, 53
Biology : New, 13 (edited by M. L. Johnson and Michael Abercrombie), *review*, 453
  A New School (Dr. F. J. Wyeth), Parts 1 and 2, *review* by D. M. Reid, 279
  Recent Marine (Dr. N. B. Eales), 24
Biology (Quantitative) Eighteenth Cold Spring Harbor Symposium on—Viruses, 333
Biology as a Career (Institute of Biology second Symposium on), 250
Biology of the Leaf Miners (Prof. E. Martin Hering), *review* by V. W. Fowler, 763
Biology and Cultivation of the Mushroom : Second International Conference on the, 506
Biology and Productivity of the Sea (Institute of Biology Symposium on), 1005
Biology and the Social Sciences : Fellowships, Scholarships and Bursaries in Dentistry, (Nuffield Foundation), 246
Biometric Conference : Third International (Biometric Society), 462
Biophysical Applications . A New Procedure for Bacterial Viability Counts and its (R. C. Valentine and Dr. J. R. G. Bradfield), 878
Biophysical Test for Aldohexoses (W. Lindquist), 393
Biosynthesis (Protein) . The Template Theory and the Role of Transpeptidation in (Dr. C. E. Dalgliesh), 1027
Biosynthesis of Proteins (Dr. P. N. Campbell and Dr. T. S. Work), 997
Biosynthesis and Energy Transport by Enzymic Reduction of 'Onium' Salts (Dr. D. W. Woolley), 323
Bird Migrants (Eric Simms), *review* by R. M. Lockley, 142
Birds . The Epigenetics of (Prof. C. H. Waddington), *review* by Prof. Nelson T. Spratt, jun., 141
  Experimental Embryology of, *review* by Prof. Nelson T. Spratt, junr., 141
Birds of Great Britain and Ireland : Check-List of the (British Ornithologists' Union), 781
Birds and Eggs (British) . Museum Collections of (Colin Matheson), 957
Birds and Wild Animals, including Marine Mammals (H. Trevor Jones), *review* by T. H. H., 143
Birefringent Crystals : Transmission-like Reflexion Fringes in (Ajit Ram Verma), 396
Birth of Neo-Positivism, *review* by F. I. G. Rawlins, 947
Black-fly Control : Adsorption of DDT on Suspended Solids in River Water and its Role in (F. J. H. Fredeen, A. P. Arnason and B. Berck), 700
Blindness (Color) . New Means of Studying, and Normal Foveal Color Vision (G. L. Walls and R. W. Mathews), *review* by Prof. W. D. Wright, 5
Blood : Grants, Scholarships and Fellowships for research on Diseases of the (Lady Tata Memorial Fund), 246
Blood Cell Studies (Red) · Isotope Curves in (D. S. Amatuzio and Robert L. Evans), 797
Blood Circulation (Amphibian) · A Cinematographic Technique, using Ultra-violet Illumination, for (J. R. Simons and Dr. A. R. Michaelis), 801 ; (G. E. H. Foxon), 801
Blood Composition and Œstrogen-Induced Oviduct Growth in the Folic-Acid Deficient Chick . Effect of Dietary Penicillin on (W. O. Brown), 845
Blood Factors, Homozygous, and the Search for New Blood Groups : 'Private' (Dr. Bruce Chown and Marion Lewis), 700
Blood Glucose-Level : Influence of the, on the Secretion of Adrenalin and Noradrenalin from the Suprarenal Medulla (Hans Dunér), 481
Blood-Group Antibody, Anti-$Jk^b$ : A New (Dr. Gertrude Plaut, Elizabeth W. Ikin, Dr. A. E. Mourant, Dr. Ruth Sanger and Dr. R. R. Race), 431
Blood Groups : 'Private' Blood Factors, Homozygosis, and the Search for New (Dr. Bruce Chown and Marion Lewis), 700
Blood Plasma . Asparagine in (J. M. Barry), 1123
Blood Transfusion : Awarded for work on (Oliver Memorial Fund), 959
Blowfly (*Calliphora erythrocephala*) : Prepupal Moult in the (Dr. P. Tate), 341
Blue-cheeked Bee-eater (Miss Hilda M. Quick), 331
Body Lice · Forms of Insecticide-Resistance in Houseflies and (Dr. J. R. Busvine), 118
*Boletus variegatus* (Sw.) Fr. : Transfer of Labelled Nitrogen from Glutamic Acid to Pine Seedlings through the Mycelium of (Prof. Elias Melin and Harald Nilsson), 134
Bolivia (Eastern) : Nomads of the Long Bow, the Siriono of (Allan R. Holmberg), 686
Bond-Energy (Phosphate) : The Concept of (Dr. R. J. Gillespie, Dr. G. A. Maw and C. A. Vernon), 1147
Bonding (Covalent) : Paramagnetic Resonance and (J. Owen and K. W. H. Stevens), 836
Bone : Low-angle X-Ray Diffraction of (Prof. A. Engström and J. B. Finean), 564
  Vitamin C and (Bone and Tooth Society Symposium on), 596
Bone Implements : Polished-edge (Dr. A. J. D. Meiring), 867
Bone-Marrow of the Golden Hamster : Production of 'Three-Group Metaphases' in the (Dr. R. Parmentier), 1029
Book Service for Industrial Operatives (National Book League), 420
Books · Recent Scientific and Technical, Supp. vi, January 31 , Supp. vi, February 28 ; Supp. viii, March 28 ; Supp. vi, April 25 ; Supp. vii, May 30 ; Supp. viii, June 27
Boric Acid : Electron Diffraction Study of the Hydrogen Bonds in (Dr. J. M. Cowley), 440
Boron and Molybdenum Fertilizers on Berseem (*Trifolium alexandrinum*) · Effect of (N. P. Datta and H. Gurubasava Raj), 134
Bose Memorial Lecture (Dr. R. C. Mazumdar), 468
Botanical Taxonomy, *review* by J. S. L. Gilmour, 585
Botanical Teaching and Training : University (Prof. V. J. Chapman), 314 , (Prof. N. P. Badenhuizen), 314
Botanist's Quo Vadis—Integration or Specialization, *review* by Prof. W. H. Pearsall, 230
Botany (Prof. Carl L. Wilson), *review*, 233
  Economic (Albert F. Hill), second edition, *review* by Prof. Ronald Good, 898
Botany (Practical) · Textbook of (Prof. R. C. McLean and Dr. W. R. Ivimey-Cook), *review* by Prof. F. W. Jane, 451
Botany at Oxford, 373
Botany of the Scottish Highlands, *review* by Dr. George Taylor, 187
Bottom Fauna of the Dogger Bank Area : Change in the Composition of the (L. Birkett), 265
Boundaries (Concentration) . Moving-Boundary Electrophoresis of Colloidal Electrolytes using (Dr. Hira Lal), 175
Boundary Phenomena and Deformation in Metals : A Dislocation Model for the Study of (W. I. Pumphrey), 218
Bovine Serum Albumin : Organic Anion Binding by Denatured (Dr. L. L. Uzman), 653
Bowen Prizes of the Scientific Instrument Manufacturers' Association of Great Britain awarded by the Institute of Physics, 959
Bowie (William) Medal of the American Geophysical Union awarded to Dr. Beno Gutenberg, 1139
Brachiopoda (Telotrematous) : Orientation of (Prof. E. Percival), 436
Brain (Human) : Vesalius on the (Charles Singer), *review* by Prof. F. J. Cole, 899
Brain Tissue . Extraction of Acetylcholine from (J. Crossland and A. J. Merrick), 267
  Inhibitory Effect of Malonate on the Respiration of, with special reference to the Potassium Effect (Y. Kimura and T. Niwa), 881
*Brassica campestris* L. Organization of Shoot Apex during the Ontogeny of (S. C. Chakravarti), 223
Brazilian Village : Cruz das Almas, a (Donald Pierson and others), 686
Breakdown of a Concrete Sea-wall . A Crystalline Hydrated Magnesium Silicate formed in the (W. F. Cole), 354
Breakdown of Methyl Methacrylate Polymer by High-Energy Radiation (Dr. A. Charlesby and M. Ross), 1153
Breeding Behaviour of the Swift (David and Elizabeth Lack), 382
Breeding-back of the Tarpan, 1008
Britain : Atomic Energy Establishments in, 820
  Atomic Energy Research in, 820
  The Changing Wild Life of (H. L. Edlin), *review* by Dr. L. Harrison Matthews, 714
  The Civil Service in, *review* by R. Brightman, 855
  Conifers in (B. Alwyn Jay), *review* by Prof. J. Doyle, 492
  Higher Technological Education in, 242
  Industry and the Universities in—Conference in Nottingham, 962

Natural Gas in, 1052
Saprophytic *Cladosporium* in (Merfyn Richards), 615
Technical and Technological Education in (C. L. Bott), 958
*See also under* Great Britain
Britain's Forests—Thornthwaite, 557
British Birds and Eggs . Museum Collections of (Colin Matheson), 957
British *Chemical Abstracts*, 18, 330
British Chemicals and their Manufacturers . Press Guide to (Association of British Chemical Manufacturers), 821
British Colonial Territories  Research in, 112, 157
British Colonies  Fisheries Research in (F. S. Russell), 159
British Commonwealth : Congress of the Universities of the, 1141
Radio Research in the, 683
British Commonwealth, 1952 . Gazetteer of Agricultural and Forestry Research Stations in the, *review* by H. G. C., 54
British Commonwealth Scientific Conference : Report of the Proceedings, 377
British Dependencies in the Caribbean and North Atlantic, 1939–1952 (Colonial Office), 380
British Dyestuffs Industry, 916
British Flora during 1952  Study of the (J. E. Lousley), 335
British Instrument Industries' Exhibition  Second, 822
British Isles · Climatological Atlas of the (Air Ministry : Meteorological Office), *review* by Prof. Gordon Manley, 809
Habitat of *Polycelis felina* (= *cornuta*) and *Crenobia alpina* in the (Dr. T. B. Reynoldson), 660
The New Flora of the (Clapham, Tutin and Warburg), (*Errata* slip for the first edition), 333
British Mollusca · Shell Regeneration in some (Dr. L. E. Wagge and T. Mittler), 528
British Pharmacopoeia, 1953 (published under the direction of the General Medical Council), *review* by Prof. J. H. Gaddum, 990
British Plastics Exhibition and Convention, 867
British Scientists of the Twentieth Century (J. G. Crowther), *review* by W L. Sumner, 97
British Universities during 1951–52  Scientific Research in, 109
British West Indies : Meteorological Expedition to the, 419
British Wild Life  Impact of Man on, *review* by Dr. L. Harrison Matthews, 714
Brittle Specimens of Wood for Sectioning . A Method of Embedding (J. F. Levy), 984
Bronchitis (Parasitic) : Fog Fever Syndrome in (J F. Michel), 940
*Brucella abortus* (Strain 19) · A Growth-Inhibitor for Streptomycin-resistant Mutants in Dense Suspensions of (Dr. A. L. Olitzki), 132
Budgets of the Scientific Departments of the University of Cambridge (Sir Lawrence Bragg), 642
Buds : Endogenous, in *Ophioglossum vulgatum* L. (Prof. C. W. Wardlaw), 88
Buffalo · Longevity and Production in the (Dr. K. A. Alim), 755
Buffaloes · Some Factors affecting Heat Tolerance of Cattle and (A. A. Asker, M. T. Ragab and M. A. Ghany), 1074
Bulgarian for Bibliographical Purposes . The Transliteration of Russian, Serbian and (Royal Society), 548
Bulk Growth of a Parasitic Protozoan : A Method for the (Dr. Joseph G. Feinberg), 1165
Burns (Experimental)  Effect of Hyaluronidase on the Mortality from (Edith Rosenberg, C. R. McComb, A. W. Farmer and W. R. Franks), 431
Bursaries : Fellowships, Scholarships and, in Dentistry, Biology and the Social Sciences (Nuffield Foundation), 246
Bursts of Signal in Long-Distance Very-High-Frequency Propagation · Multiple (G. A. Isted), 617
Bushmen of South-West Africa · Absence of the Sickle Cell Trait in the (S. B. Griffiths), 577

CADBURY (Edward) Lectures in the University of Birmingham for 1950 (E. A. Milne), *review* by Sir Harold Spencer Jones, 584
*Calanus finmarchicus* and related Forms (Dr. S. M. Marshall, A. P. Orr and C. B. Rees), 1163
Calcite Crystals and Gaseous Carbon Dioxide . Exchange of Carbon-13 Dioxide between (R. A. W. Haul, L. H. Stein and J. W. L. de Villiers), 619
Calcium Chloride  Effect of, on Choline Esterase (Dr. C. van der Meer), 78
Calculating Machinery (Large-Scale Digital) · Proceedings of a Second Symposium on (jointly sponsored by the Navy Department, Bureau of Ordnance and Harvard University), *review* by M. V. Wilkes, 54
Calculation (Rigorous)  An Electrostatic Single Lens permitting (Dr. Peter Schiske), 443
Calculus · The Ricci (Prof. H. S. Ruse), 61
Calendar · The, Past, Present and Future (Sir Harold Spencer Jones), 1004
Calf Thymus Extract · Vitamin $B_1$, Content of (W. J. Kaipainen, Dr. Antti Telkka and Kimmo K. Mustakallio), 845
California . Sardine Fishery of, 872
*Calliphora erythrocephala*  Prepupal Moult in the Blowfly (Dr. P. Tate), 341
Camera (Pocket-Lens)  Conifers under the, *review* by Prof. J. Doyle, 492
Canada (East Coast of)  Swarming of *Nereis succinea* (Leuckart) off the (C. Berkeley and E. Berkeley), 847
Canoe in use in Vendaland  A Dug-out (Dr. A. C. Hoffman), 867
Capper Pass Awards by the Institution of Mining and Metallurgy and the Institute of Metals, 959
Carbohydrate Metabolism in Protozoa and Metal-binding Substances (J. F. Ryley), 747
Carbohydrates and Polyols . A New Spraying Agent for Paper Chromatography of (D. J. D. Hockenhull), 982
Carbon . An Unusual Form of (W. R. Davis, R. J. Slawson and Dr. G. R. Rigby), 756
Carbon Dioxide  Dissociative Chemisorption of, on Solid Catalysts (Prof. T. Kwan and Y. Fujita), 705
Carbon Dioxide (Gaseous)  Exchange of Carbon-13 Dioxide between Calcite Crystals and (R. A. W. Haul, L. H. Stein and J. W. L. de Villiers), 619
Carbon Dioxide Concentration and Maximum Quantum Yield in Photosynthesis (Prof. E. Steemann Nielsen), 1106
Carbon Dioxide Differences across the Kidney : Effect of Nervous Stimulation on the Arterio-Venous Oxygen and (Dr. Joseph H. Cort), 784
Carbon Dioxide Fixation in Mouse Liver : Short-Term (Lemuell C Leeper, Felix Friedberg and Lawrence M. Marshall), 748
Carbon-13 Dioxide · Exchange of, between Calcite Crystals and Gaseous Carbon Dioxide (R. A. W. Haul, L. H. Stein and J. W. L. de Villiers), 619
Carbonate : Crystal Structure of Barium-Strontium-Calcium Triple (Jitsuo Terada), 517
Carboxyl End . Stepwise Degradation of Polypeptides from the (R. A. Boissonnas), 304
Carcinogenic Action of Beta-Irradiation on Mouse Epidermis  Latent (Dr. Philippe Shubik, A. Robert Goldfarb, A. C. Ritchie and Hermann Lisco), 934
Cardanol and Cardol : Separation and Structural Determination of the Olefinic Components of Poison Ivy Urushiol (W. F. Symes and Prof. C. R. Dawson), 841
Cardol (Poison Ivy Urushiol, Cardanol and) : Separation and Structural Determination of the Olefinic Components of (W. F. Symes, and Prof. C. R Dawson), 841
*Cardwellia sublimis* F. Muell. : An Occurrence of Aluminium Succinate in (L. J. Webb), 656
Career · Biology as a (Institute of Biology second Symposium on), 250
Physics as a (Norman Clarke), *review*, 811
Careers in Agricultural Research (Agricultural Research Council), 330
Careers in Biochemistry (Prof. G. F. Marrian), 780
Careers in the Petroleum Industry (Shell Petroleum Co., Ltd. Booklets on), 1004
Caribbean and North Atlantic . British Dependencies in the, 1939–1952 (Colonial Office), 380
Carnegie (Andrew) Silver Medal for 1952 of the Iron and Steel Institute awarded to Dr. E. T. Turkdogan, 506
Carolina (South) · Flora and Fauna of, 677
Carp Muscle · Myoglobin from (G Hamoir), 345
Caste and Class in India (Prof. G. S. Ghurye), *review* by Prof. J. H. Hutton, 810
Catalase-negative Bacteria  Susceptibility of, to Ultra-violet Irradiation (Sidney Mittler and John A. Laverty), 793
Catalysis of the Decarboxylation of Oxalo Acetic Acid  Metal Ion (Dr. R. J. P. Williams), 304
Catalysts (Solid)  Dissociative Chemisorption of Carbon Dioxide on (Prof. T. Kwan and Y. Fujita), 705
Cattle  Indirect Determination of Water Retention in, as a means of estimating Energy Exchange (K. L Blaxter and J. A. F. Rook), 609
Cattle and Buffaloes  Some Factors affecting Heat Tolerance of (A. A. Asker, M. T. Ragab and M. A Ghany), 1074
Cecil Peace Prize for 1952 of the Association of Universities of the British Commonwealth awarded to K H Dawson, 549
Cell Biology · Eighth International Congress of the International Society for, 421
Cell Membranes. Insulin and the Permeability of, to Glucose (E. J. Ross), 125
Cell Walls (Plant) · The Molecular Architecture of (Dr. R. D. Preston), *review* by Dr. K Wilson, 98
Cell Walls of the Marine Alga *Spongomorpha* · Variability in the X-Ray Diagram of the (E. Nicolai and Dr. R. D Preston), 752
Cells . The Function and Location of Enzymes in (Royal Society Discussion on), 815
Cells (Bean Root) · Cytoplasmic Particles in (Dr. E. Robinson and R. Brown), 313 ; (G. L. Brown, S. Fitton Jackson and J. Chayen), 1113
Cells (Binucleate) : Percentage of, in the Livers of Adult Rats (Marion F. Harrison), 611
Cells (Living) · Refractometry of (Dr. R. Barer, K. F. A. Ross and S. Tkaczyk), 720
Cells (Plant)  Cytoplasmic Localization of Nucleic Acids in (J. Chayen and K. P. Norris), 472
Cells from Chick Embryos : Experimental Dissociation of (Dr. Sivatosh Mookerjee), 796
Cellulolytic Activity of *Cellvibrio* . Purification and (J. P. Voets and J K. Van Hove), 1073
Cellulose in Aqueous Solutions of Inorganic Salts : Specific Volume of (Dr. S. M. Neale and G. R. Williamson), 842
*Cellvibrio* · Purification and Cellulolytic Activity of (J. P. Voets and J. K. Van Hove), 1073
Census 1951, Great Britain  One Per Cent Sample Tables (General Register Office and General Registry Office Scotland), 816
Census of England and Wales  Decennial Supplement for 1931 for the, 549
Census in Iraq  Agricultural (Dr. K. G. Fenelon), 821
Centenaries in 1953  Scientific (Joan M. Eyles), 10
Centenary Lecture of the Chemical Society (Prof. A. Tiselius), 290
Centrifugation Potentials in Sols of Silver Iodide (Prof. A. J. Rutgers and P. Nagels), 568
Centrifuges and *p*H Meters (Institute of Biology Reports on), 155
Centromere . 'Diffuse', and other Cytological Observations on Two Desmids (G. C. King), 181
Cephalosporin *N*, a New Type of Penicillin (Dr. E. P. Abraham, G. G. F. Newton, K. Crawford, H. S. Burton and C. W. Hale), 343
*Cerastium arcticum* Lange (Olive E. Brett), 527
Cercariae : Probable Relationship between the *Rhodometopa* Group of, and the Trematode Genus *Renicola* Cohn (C. A Wright), 1072
*Cercopithecus ascanius schmidti* : The African Red-tailed Monkey (Dr. A. J. Haddow), 18
Ceylon · A Manual on the Weeds of the Major Crops of (Dr. J. C. Haigh and representatives of the Tea, Rubber and Coconut Research Institutes), *review* by Sir Edward Salisbury, 587
Chafer, *Phyllopertha horticola* L. : Absorption of Water by the Egg of the Garden (Roger Laughlin), 577
*Chauliodus sloani* Schneider . The Feeding Mechanisms of a Deep-Sea Fish (the late Dr. V. V. Tchernavin), 1096
Chelate Compounds : Effects of some, upon the Formation *in vitro* of Melanin (Saburo Isaka and Shuzo Ishida), 303
Chelating Agents . Activation of Enzymes by (S. M. Altmann and Dr. E. M. Crook), 76
*Chemical Abstracts* . *British*, 18, 330
Chemical Apparatus in the U.S A. (Office of European Economic Co-operation, Technical Assistance Mission No. 23), 204
Chemical Aspects of Normal Growth : Some (Prof F. Bergel), 905
Chemical Constitution of the *L*-Forms of Bacteria (Dr. Roger Vendrely and Prof. Robert Tulasne), 262

Chemical Dosimetry : Use of Tracers in (Gosta Rodstam and Prof. The Svedberg), 648
Chemical Dosimetry at High Dose-rates (Dr. N. Miller), 688
Chemical Engineering : Second Session of, 776
Chemical Equipment in the United States : Industrial (Prof. H. E. Watson), 204
Chemical Industries . Our Changing, an Appraisement (Dr. Herbert Levinstein), 916
Chemical Industry : Glass in, 1052
Chemical Industry (U.K.) . Production and Utilization of Petroleum Raw Materials in the (London Section of the Society of Chemical Industry and the Institute of Petroleum Symposium on), 679
Chemical Meetings in Paris during June, 776
Chemical Research : Ramsay Memorial Fellowships for, 421
Chemically Modified '*Aspergillus niger β*-Glucosidase' : Relative Specificity of the (Dr. Yutaka Murakami), 522
Chemicals (British) : Press Guide to, and their Manufacturers (Association of British Chemical Manufacturers), 821
Chemicals used in Crop Protection : Guide to the (H. Martin and J. R. W. Miles), 1004
Chemicals Industry in Great Britain : Petroleum, 679
Chemie : Fouriersynthese von Kristallen und ihre Anwendung in der (Prof. Werner Nowacki), *review* by Dr. C. H. Carlisle, 1131
Chemisorption : Dissociative, of Carbon Dioxide on Solid Catalysts (Prof. T. Kwan and Y. Fujita), 705
Chemistry : Education in (London Sections of the British Association of Chemists and the Royal Institute of Chemistry Discussion on), 156, 465
  Organic, in the University of Leeds, 418
  Physical, in the Chester Beatty Research Institute, 503
  Physical, at Manchester, 1051
  Practical, for Schools and Intermediate Students (J. W. Davis), *review*, 900
  Radioactivity Applied to (edited by Arthur C. Wahl and Norman A. Bonner), *review* by Prof. F. A. Paneth, 625
  Short Course in, for Teachers from Technical Colleges (Ministry of Education), 421
Chemistry (Analytical) : Summer School in (Royal Institute of Chemistry and the Society of Public Analysts and other Analytical Chemists), 333
Chemistry (Industrial) : Twenty-sixth International Congress of (Société de Chimie Industrielle), 776
Chemistry (Organic) : Some Recent Developments in (Dr. Neil Campbell), 780
Chemistry (Physical) : An Advanced Treatise on (Prof. J. R. Partington), Vol. 3, The Properties of Solids, *review* by R. P. Bell, 853
  Annual Review of (edited by G. K. Rollefson and R. E. Powell), Vol. 3, *review* by Dr. H. A. Skinner, 364
  A Treatise on (edited by Prof. Hugh S. Taylor and Samuel Glasstone), third edition, Vol. 2, States of Matter, *review* by R. P. Bell, 853
  Treatises on, *review* by R. P. Bell, 853
Chemistry (Protein) . Advances in (edited by M. L. Anson, Kenneth Bailey and John T. Edsall), Vol. 7, *review*, 276
Chemistry (Pure and Applied) : Thirteenth International Congress of, 245
Chemistry in Action (Prof. George M. Rawlins and Alden H. Struble), second edition, *review* by G. F., 1039
Chemistry and Inter-Relationships of Endocrine Systems and their Psychological Effects (Society for Visiting Scientists Discussion on), 509
Chemistry and Physics in Spain (Sir Eric Rideal), 915
Chemistry's Debt to Radioactivity, *review* by Prof. F. A. Paneth, 625
Chick (Folic-Acid Deficient) : Effect of Dietary Penicillin on Blood Composition and Œstrogen-induced Oviduct Growth in the (W. O. Brown), 845
Chick Chorion : Growth of Influenza Virus in the (Alick Isaacs and Dr. Forrest Fulton), 90
Chick Embryos : Experimental Dissociation of Cells from (Dr. Sivatosh Mookerjee), 796
Chicken Embryo : Growth and Axon Formation in the Midbrain of the (Dr. R. J. O'Connor), 131
Child (School) : Health of the, 996
Child's Mind . Formation of Symbols in the, *review* by Prof. John Cohen, 450
Childhood : Play, Dreams and Imitation in (Prof. Jean Piaget), translated by C. Gattegno and F. M. Hodgson, *review* by Prof. John Cohen, 450
Chinese Science Revisited (Dr. Joseph Needham) (1), 237 ; (2), 283
*Chlorella* . Demonstration of Transaminase Systems in the Alga (J. W. Millbank), 476
Chlorinated Phenyl Benzenesulphonates : Toxicity of, to Winter Eggs of the Fruit Tree Red Spider Mite, *Metatetranychus ulmi* (Koch), (Dr. A. H. M. Kirby and R. P. Tew), 479
Chlorine Dioxide with Flour : Interaction of—Certain Chemical Aspects (Dr. T. Moran, Dr. J. Pace and E. E. McDermott), 103
Chlorophyllides (Ethyl) : Absorption Spectra of the (W. F. Watson), 842
Choice and Judgment : Factors affecting (D. Sheppard), 847 ; (Dr. R. G. Hopkinson), 848
Cholesterol in New-born Rats : Lipoids and (Zdenek Dvorák), 432
Choline : Bacterial Degradation of (B. P. Eddy), 573
Choline in the Oxidation of Fatty Acids by the Isolated Liver : Role of (Camillo Artom), 347
Choline Esterase : Effect of Calcium Chloride on (Dr. C. van der Meer), 78
Choline Oxidase in Plant Tissues : Occurrence of (Dr. B. T. Cromwell and S. D. Rennie), 79
Cholinesterases and the Anti-cholinesterase Drugs : Bibliography on (Dr. K.-B. Augustinsson), 729
Christian Church : Religious Dances in the, and in Popular Medicine (Prof. E. Louis Backman), translated by E. Classen, *review* by M. C. Burkitt, 667
Christian Idea of God : Modern Cosmology and the (E. A. Milne), *review* by Sir Harold Spencer Jones, 584
Chromatograms (Paper) : Colour Reactions on, by a Dipping Technique (Ivor Smith), 43
  Detection of Phosphate Esters on (H. E. Wade and D. M. Morgan), 529
  Multi-spots in (Dr. A. S. Curry), 1026
Chromatographic Procedure : Determination of Glycerol in Fermentation Solutions—a Rapid (A. F. Williams), 655
Chromatography . Filter-Paper Disk (H. Proom and A. J. Woiwod), 42 ; (Prof. K. V. Giri), 1159
  Paper, of Œstrogens (P. H. Jellinek), 750
  Paper, of Phosphate Esters (E. Fletcher and Dr. F. H. Malpress), 838
  Paper, of Thioureas (Dr. Anders Kjaer and Kurt Rubinstein), 840
  Paper Partition, of Natural Œstrogens (Dr. C. Heusghem), 42
Chromatography (Paper) : Detection of some Precursors of Adrenaline by (D. M. Shepherd and Dr. G. B. West), 1160
  Ion Exchange in (J. B. Schute), 839
  A New Method for the, of Oligosaccharides (R. J. Bayly and Dr. E. J. Bourne), 385
  A New Spraying Agent for, of Carbohydrates and Polyols (D. J. D. Hockenhull), 982
  Use of Ion-Exchange Resins in, of Sugars (Dr. L. I. Woolf), 841
  Use of Unneutralized Hydrolysates in, of Sugars (Blanche D. E. Gaillard), 1160
Chromatography (Paper-Partition) . Identification of Recessive Gene Heterozygotes by means of (Prof. A. A. Buzzati-Traverso), 575
Chromatography of the Growth Substances in Plant Extracts (Prof. T. A. Bennet-Clark and N. P. Kefford), 645
Chromatography of Phycocyanin (E. C. Wassink and H. W. J. Ragetli), 376
Chromatophores and Eyespot in *Euglena* . Experimental Elimination of (E. G. and O. Pringsheim), 244
Chromosomal Re-arrangements in the Progeny of *Drosophila* Males treated with Mustard Gas (Dr. M. Mehtab), 262
Chromosome Method (Salivary) : Extension of the, to *Anopheles claviger, quadrimaculatus* and *aquasalis* (Dr. G. Frizzi), 1072
Chromosome Numbers in *Holcus mollis* (A. R. Beddows and Keith Jones), 928
Chromosomes : The Anatomy of, *review* by Dr. C. D. Darlington, 139
  Doubling of, Induced by Gloriosine isolated from *Gloriosa superba*, Linn. (L. S. S. Kumar), 791
Chromosomes of the Genus *Corchorus* (N. S. Rao and R. M. Datta), 754
Chromosphere . Kinetic Theory of the (Shotaro Miyamoto), 375
Chromous Acetate (Capric and) : X-Ray Evidence for Metal-to-Metal Bonds in (J. N. van Niekerk and R. F. L. Schoening), 36
Chronographs : Catalogue of Stop-watches and (Camerer Cuss and Co.), 636
Church (Christian) : Religious Dances in the, and in Popular Medicine (Prof. E. Louis Backman), translated by E. Classen, *review* by M. C. Burkitt, 667
Cilia (Plant) . Electron Microscopy of (Prof. I. Manton, B. Clarke, A. D. Greenwood and E. A. Flint), 289
Cilia of the Green Algae : Number of Fibrils in the (Prof. I. Manton), 485
Cinematographic Technique, using Ultra-violet Illumination, for Amphibian Blood Circulation (J. R. Simons and Dr. A. R. Michaelis), 801 ; (G. E. H. Foxon), 801
Circuits and their Intrinsic Safety : A Theoretical Approach to the Problem of determining the Relationship between the Constants of (Dr. B Roston), 397
Cirripede Crustacea (Parasitic) : Hæmoglobin and Biliverdin in (Prof. H. Munro Fox), 162
City of the Incas : Lost, the Story of Machu Picchu and its Builders (Hiram Bingham), *review*, 453
Civil Servants : Political Activities of, 1140
Civil Service in Britain, *review* by R. Brightman, 855
Civil Service in Great Britain, *review* by R. Brightman, 362
Civil Service Fellowships : Colonial, 777
  Dominion, 777
  Home (Commonwealth Fund), 596
Civil Service Works : How the (Bosworth Monck), *review* by R Brightman, 855
Cladoceran from the Plankton as a Possible Indicator for the Presence of the Nile Flood off the Israeli Coast (Dr. B Komarovsky), 937
*Cladosporium* in Britain : Saprophytic (Merfyn Richards), 615
Class in India : Caste and (Prof. G. S. Ghurye), *review* by Prof. J. H. Hutton, 810
Classification of Myxoma and Fibroma Viruses (Prof. Frank Fenner), 562
Clay Minerals : Randomly Stacked Layers in (Dr. Douglas M. C. MacEwan), 616
Clay–Water Relationships (Clay Minerals Group of the Mineralogical Society Discussion on), 681
Climatological Atlas of the British Isles (Air Ministry : Meteorological Office), *review* by Prof. Gordon Manley, 809
Climatology (Micro-) : Bases of (Sir David Brunt), 322
Clinical Research : Fellowships in (Medical Research Council), 20
Cloud Chamber : Cosmic Rays and the, *review* by J. R. Atkinson, 495
Cloud Chamber Photographs of the Cosmic Radiation (G. D. Rochester and J. G. Wilson), *review* by J. R. Atkinson, 495
Clouds (Magellanic) . Distances of the (Dr. A. D. Thackeray and A. J. Wesselink), 693
Clouds and Weather : Shore Life, Fish, (H. Trevor Jones), *review* by T. H. H., 143
Clove Tree, *Eugenia aromatica* . Sudden-Death Disease of the (Dr. F. J. Nutman and F. M. Roberts), 128
Coagulase-destroying Factor produced by variants of *Staphylococcus aureus* (Dr. Iwo Lominski, Douglas D. Smith and Robert B. Morrison), 214
Coal (Bituminous) : Structural Skeleton in a (Katsuya Inouye), 487
Coal Dust : Microscopical Identification of the Constituents of (Dr. R. G. H. B. Boddy), 928
Coal Mining . Research in, 676
Coal Products : Infra-Red Spectra of Coals and (C. G. Cannon), 308
Coals (Coking) : Plastic Properties of (Dr. J. Bronowski, D. Fitzgerald, D. W. Gillings and D. C. Rhys-Jones), 389
Coals and Coal Products : Infra-Red Spectra of (C. G. Cannon), 308
Coconut Milk : Dividing Nuclei in (Miss Mridula Dutt), 799
Cod and other Fish-liver Oils : Occurrence of Vitamin E in (Dr. F. Brown), 790
Coelacanth : The Second (Prof. J. L. B. Smith), 99
  Investigation of the (Prof. J. L. B. Smith), 389
Coelacanthid Fish : A Further, 17
Coenzyme A : Structure of (Dr. J. Baddiley, E. M. Thain, G. D. Novelli and F. Lipmann), 76
Coincidence and Overlap Errors in the Automatic Counting and Sizing of Particles (J. R. Hodkinson), 351
Coking Coals : Plastic Properties of (Dr. J. Bronowski, D. Fitzgerald, D. W. Gillings and D. C. Rhys-Jones), 389

Cold Spring Harbor : Eighteenth Symposium on Quantitative Biology—Viruses, 333
Cold Working of Non-Ferrous Metals and Alloys (Institute of Metals Symposium on Metallurgical Aspects of the), *review* by Dr. A. J. Kennedy, 992
Collagen : Decarboxylation of (Dr. Robert L. Sykes), 654
  The Nature and Structure of (Colloid and Biophysics Committee of the Faraday Society Discussion on), 110
  Reticulin and (S. G. Tomlin), 302
Colloidal Dispersions (Earl K. Fischer), *review* by Dr. A. S. C. Lawrence, 142
Colloidal Electrolytes : Moving-Boundary Electrophoresis of, using Concentration Boundaries (Dr. Hira Lal), 175
Colloidal Particles : Some Applications of the Separation of Large Molecules and (Prof. A. Tiselius), 290
Colonial Agricultural Development : Insecticides and (Colston Research Society Symposium on), 824
Colonial Civil Service Fellowships, 777
Colonial Exhibitions · Dominion and (Trinity College, Cambridge), 377
Colonial Research 1951–1952 (Colonial Office), 112
Colonial Territories (British) : Research in, 112, 157
Colonies : Problems of Parliamentary Government in (Hansard Society), 1130
Colonies (British) . Fisheries Research in (F. S. Russell), 159
Color Blindness and Normal Foveal Color Vision New Means of Studying (G. L. Walls and R. W. Mathews), *review* by Prof. W. D. Wright, 5
Color Vision (Foveal) · New Means of Studying Color Blindness and Normal (G. L. Walls and R. W. Mathews), *review* by Prof. W. D. Wright, 5
Colour Reactions on Paper Chromatograms by a Dipping Technique (Ivor Smith), 43
Colour Vision . 'Maxwell's Spot' in, *review* by Prof. W. D. Wright, 5
Colour Vision Variations . Inheritance of Minor (Dr. R. W. Pickford), 1167
Column Procedures for the Salt Fractionation of Enzyme Preparations (Sigmund Schwimmer), 442
Combustion of Solid Fuel Particles . Rates of (G. A. E. Godsave), 86
'Comet' Air-Liner (C. T. Wilkins), 249
Commonwealth . The Yearbook of the Universities of the, 1953 (published for the Association of Universities of the British Commonwealth), *review*, 1039
Commonwealth (British) : Congress of the Universities of the, 1141
  Radio Research in the, 683
Commonwealth (British), 1952 : Gazetteer of Agricultural and Forestry Research Stations in the, *review* by H. G. C., 54
Commonwealth Scientific Conference, British. Report of the Proceedings, 377
Community Factor in Modern Technology (Jerome F. Scott and R. P. Lynton), 533
Compensator in Electrophoresis : Photoelectric Control of the (Dr. R. L. Warren and Dr. P. A. Chartwood), 353
Composition of the Bottom Fauna of the Dogger Bank Area . Change in the (L. Birkett), 265
Compounds (Aromatic) : Graphitic Acid from, by Peroxide Treatment (G. A. Bottomley and J. G. Blackman), 620
  Optical Exaltation in (D. W. van Krevelin, L. Blom and H. A. G. Chermin), 1075
Computers · D. C. Analogue, review by Dr. M. V. Wilkes, 1132
  Electronic Analog (D-C Analog Computers), (Dr. Granino A. Korn and Theresa M. Korn), *review* by Dr. M. V. Wilkes, 1132
  Electronic Digital (American Institute of Electrical Engineers and the Institute of Radio Engineers Conference on), 599
Computing (Automatic) : Numerical Methods and, in Atomic Theory (Symposium in the University Mathematical Laboratory, Cambridge), 868
Computing and Control Circuits : Synthesis of Electronic (Staff of the Computation Laboratory of Harvard University), *review* by Dr. M. V. Wilkes, 453
Conceptual Situation in Physics and its Prospects of Development (Prof M. Born), 290
Concrete : Prestressed (Prof. Kurt Billig), *review* by W. Merchant, 854
Concrete Sea-wall · A Crystalline Hydrated Magnesium Silicate formed in the Breakdown of a (W. F. Cole), 354
Conductivity induced in Insulators by X-Rays · Effect of Temperature on the (J. F. Fowler and Dr. F. T. Farmer), 1020
Conductivity in a Low-frequency Electric Discharge Langmuir Adsorption as a Determinant of (A. P. Saxena, M. G. Bhatawdekar and N. A. Ramaiah), 929
Configuration of the Purine Nucleotides in Ribonucleic Acids : Natural—Chemical Hydrolyses of the Dinucleoside Phosphates (P. R. Whitfeld and Dr. Roy Markham), 1151 , Enzymatic Splitting of Purine Internucleotide Linkages (Dr. Leon A. Heppel, Dr. Roy Markham and R. J. Hilmoe), 1152
Configurations of Polypeptide Chains Compound Helical—Structure of Proteins of the $\alpha$-Keratin Type (Prof. Linus Pauling and Prof. Robert B. Corey), 59
Conflicts of Loyalties ? (Present Question Conference on), 665
Conformal Mapping (Prof. Zeev Nehari), *review* by Prof. H. T. H. Piaggio, 715
Conformal Representation (C. Carathéodory), second edition, *review* by Prof. H. T. H. Piaggio, 715
Conformation of Tropane Alkaloids (Dr. Ajay K. Bose and Dilip K. Roy Chaudhuri), 652
Congo (Belgian) . Pedo-Botanical Surveys in the, 154
Conifers in Britain (B. Alwyn Jay), *review* by Prof. J. Doyle, 492
Conifers under the Pocket-Lens Camera, *review* by Prof. J. Doyle, 492
Consciousness during Curarization : Assessment of (Phyllis G. Croft), 261
*Conservation, Studies in*, No. 1, 199
Conservation of Vegetation in Africa : Management and, *review* by Sir Edward Salisbury, 496
Conservation of World Resources, 1
Constants of Circuits and their Intrinsic Safety . A Theoretical Approach to the Problem of determining the Relationship between the (Dr. B. Roston), 397
Constituents of Coal Dust : Microscopical Identification of the (Dr. R. G. H. B. Boddy), 928
Contamination of *Azotobacter chroococcum* by Gram-negative Bacterial Rods (Ernest A. Gray), 1163
Contamination of Nectar with the Systemic Insecticide 'Schradan' (Dr. G. D. Glynne Jones and Dr. W. D. E. Thomas), 263
Continental Drift · The South Atlantic—Land Bridges or (Prof. Arthur Holmes), 669
Control · Automatic and Manual (Papers contributed to the Conference at Cranfield, 1951), *review* by Dr. A. J. Kennedy, 1133
Control Circuits : Synthesis of Electronic Computing and (Staff of the Computation Laboratory of Harvard University), *review* by Dr M. V. Wilkes, 453
Controlling Effect of Salts on the Activity of the Cytochrome Oxidase (Prof. H. Lundegårdh), 477
Convolution Operations : Calculation of Electron-Density Distribution in Crystals with the Help of (R. Hosemann and S. N. Bagchi), 785
Cook (James) Medal for 1952 of the Royal Society of New South Wales awarded to Prof. W. L. Waterhouse, 678
Copolymers ('Block') : A Flow Method for the Synthesis of (J. A. Hicks and Prof. H. W. Melville), 300
Copper under Stress Pulses : Creep of (Dr. A. J. Kennedy), 927
Copper Supplement . Effect of a, to the Rations of Milking Cows (Dr. George Dunlop), 356
Copyright Convention Universal (Unesco), 956
*Corchorus* : Chromosomes of the Genus (N. S. Rao and R. M. Datta), 754
Coronation : The, 943
  Radio and the, 1050
  Tradition and the (Archibald G. B. Russell), 948
Coronation Honours, 1002
Cortex (Visual) : Pattern Discrimination and the (D. A. Sholl and A. M. Uttley), 387
Corticoids (Antitumorigenic) : Structural Features of (Dr. Elvira Mardones, Dr. Rigoberto Iglesias and Prof. A. Lipschutz), 1026
Cortisone : Action of, on the Polymerization of Actin (J. B. Cowie and Prof. R. H. Thorp), 1067
  Effect of, on Tissue Potentials in Man (Geoffrey E. Loxton and David Le Vay), 524
Cortisone and the Suprarenal Cortex (Società Italiana di Reumatologia Symposium on), 463
*Coryphaena hippurus* (L.) in the Western Indian Ocean : Catches of (F. Williams), 703
Cosmetology : Seventh International Congress of Aesthetics and, 776
Cosmic Radiation · Cloud Chamber Photographs of the (G. D. Rochester and J. G. Wilson), *review* by J. R. Atkinson, 495
Cosmic-Ray Intensity and the Temperature of the Upper Atmosphere (Harald Trefall), 888
Cosmic-Ray Solar Daily Variation : World-wide Changes in the Phase of the (T. Thambyahpillai and Dr. H. Elliot), 918
Cosmic Rays (University of Toulouse Colloquium on), 332
  Light Pulses from the Night Sky associated with (Dr. W. Galbraith and Dr. J. V. Jelley), 349
Cosmic Rays and the Cloud Chamber, *review* by J. R. Atkinson, 495
Cosmology and the Christian Idea of God : Modern (E. A. Milne), *review* by Sir Harold Spencer Jones, 584
Cotton in Culture Filtrate of *Fusarium vasinfectum* : Rooting of Cut Shoots of (R. Kalyanasundaram and K. Lakshminarayanan), 1120
Cotton Industry War Memorial Trust Scholarship in Textile Technology (Textile Institute), 506
Counting Small Particles suspended in a Fluid through a Tube . A Device for (Dr. P. J. Crosland-Taylor), 37
Counting and Sizing of Particles : Coincidence and Overlap Errors in the Automatic (J. R. Hodkinson), 351
Countryside . The—a Medium for Teaching (Association of Agriculture, the Institute of Rural Life at Home and Overseas, and Seale-Hayne Agricultural College Course on), 549
Covalent Bonding Paramagnetic Resonance and (J. Owen and K. W. H. Stevens), 836
Cow's Milk · Differences in the Vitamin $B_{12}$ Content of, during the Last Month Indoors and the First Week at Pasture (E. E. van Koetsveld), 483
  Microsomal Particles of Normal (Dr. R. K. Morton), 734
Cows (Lactating) : Feeding of Seaweed Meal to (Dr. George Dunlop), 439
Cows (Milking) : Effect of a Copper Supplement to the Rations of (Dr. George Dunlop), 356
Crabs (Spider) : Behaviour of, in the Presence of Octopuses (H. J. Beal), 887
Creatinine : Determination of, by the Jaffé Reaction (Dr. G. R. Hervey), 1125
Creative Process : The, a Symposium (edited by Brewster Ghiselin), 1034
Creator : Kinematic Relativity and the, *review* by Sir Harold Spencer Jones, 584
Credo : A Psychiatrist's, *review* by Dr. Clifford Allen, 232
Creep of Copper under Stress Pulses (Dr A. J. Kennedy), 927
*Crenobia alpina* in the British Isles : Habitat of *Polycelis felina* (= *cornuta*) and (Dr. T. B. Reynoldson), 660
*Creontiades pallidus*, Ramb. : A Predator on (Alan Goodman), 886
Croonian Lecture for 1953 of the Royal Society (Sir Ronald Fisher), 290
Crop Production . Soil Fertility and—Meeting in Dublin (T. Walsh), 67
Crop Protection—Symposium in Ghent (Prof. R. L. Wain), 1102
Crop Protection . Guide to the Chemicals used in (H. Martin and J. R. W. Miles), 1004
Crops of Ceylon . A Manual on the Weeds of the Major (Dr. J. C. Haigh and representatives of the Tea, Rubber and Coconut Research Institutes), *review* by Sir Edward Salisbury, 587
Cross (Dorothy Temple) Research Fellowships in Tuberculosis (Medical Research Council), 111
Crustacea : The X-Organ of (D. B. Carlisle and L. M. Passano), 1070
Crustacea (Parasitic Cirripede) : Haemoglobin and Biliverdin in (Prof. H. Munro Fox), 162
Crustaceans, Insects and Vertebrates . Neurosecretory Pathways in the Head of (Prof. Bertil Hanström), 72
Cruz das Almas, a Brazilian Village (Donald Pierson and others), 686
Crystal class *m* : Alleged Optical Activity in (Dr. D. Rogers), 929
Crystal Structure . Fourier Synthesis of, *review* by Dr. C. H. Carlisle, 1131
Crystal Structure of Barium-Strontium-Calcium Triple Carbonate (Jitsuo Terada), 517
Crystal Structure of Histidine Hydrochloride Monohydrate (Jerry Donohue), 258
Crystal Structure of *iso*Nicotinic Acid Hydrazide (L. H. Jensen), 217
Crystal Structure Analysis . A New Application of EDSAC to (W. Cochran and A. S. Douglas), 1112

Crystalline Chain Orientation in Polythene Film : Crossed Amorphous (D. R. Holmes, R. G. Miller, R. P. Palmer and C. W. Bunn), 1104
Crystalline Hydrated Magnesium Silicate formed in the Breakdown of a Concrete Sea-wall (W. F. Cole), 354
Crystalline Materials after Grinding Electrical Conductivity of certain (J. S. Dryden and Dr. R. J. Meakins), 307
Crystalline Potato Phosphorylase and Q-Enzyme : A Simple Method for the Preparation of (H. Baum and Dr. G. A. Gilbert), 983
Crystalline Synthetic Polymers . Morphology of (A. Keller), 170
Crystalline Trypsin (Dr. M. Bier and Prof. F. F. Nord), 1022
Crystallographic Methods (Optical) Postgraduate Summer School in (Department of Inorganic and Physical Chemistry of the University of Leeds in association with the Department of Adult Education and Extra-Mural Studies), 822
Crystallographic Technology : X-Ray (André Guinier), English translation by T. L. Tippell, edited by Prof. Kathleen Lonsdale, *review* by Dr. W. A. Wooster, 586
Crystallographical Structure Reports for 1949, *review* by H. J. Grenville-Wells, 1084
Crystallography (X-Ray) : International Tables for, Vol. 1, Symmetry Groups (edited by Norman F. M. Henry and Kathleen Lonsdale), *review* by Prof. P. P. Ewald, 944
Crystals : Calculation of Electron-Density Distribution in, with the Help of Convolution Operations (R. Hosemann and S. N. Bagchi), 785
Crystals (Birefringent) : Transmission-like Reflexion Fringes in (Ajit Ram Verma), 396
Crystals (Metal Single) : A Special Kind of Growth Structure in (Dr. F. Blaha), 650
Crystals (Real) : Progress in the Study of, *review* by Dr. B. A. Bilby, 991
Crystals (Stearic Acid) : Growth and Optical Properties of (P. M. Reynolds and Ajit Ram Verma), 486
Crystals of an Aluminium-Copper Alloy : Exudation of Material from Slip Bands at the Surface of Fatigued (P. J. E. Forsyth), 172
Crystals of Titanium : Preparation of Single, and their Mode of Deformation (Dr. A. T. Churchman), 706
Crystals of Zinc Kramer and Russell Effects with Single (L. Grunberg and Dr. K. H. R. Wright), 890, *erratum*, 914
Cultivation of *Amoeba proteus* . Effect of Thyroid Gland on the (Sister Monica Taylor), 313
Culture (Sterile) : Pea Embryos in (W. Kruyt), 420
Culture Filtrate of *Fusarium vasinfectum* : Rooting of Cut Shoots of Cotton in (R. Kalyanasundaram and K. Lakshminarayanan), 1120
Cupric and Chromous Acetate . X-Ray Evidence for Metal-to-Metal Bonds in (J. N. van Niekerk and R. F. L. Schoening), 36
Curarization . Assessment of Consciousness during (Phyllis G. Croft), 261
Curd Feeding : Influence of Sulphaguanidine on the Intestinal Flora and Thiamine Synthesis brought about by (S. Balakrishnan and Dr. R. Rajagopalan), 608
Cuticle (Insect) . Permeability of, to Aqueous Stains and Vulnerability to Insecticides (S. Mukerji and S. N. Chatterjee), 119
Cyano Links of Acrylonitrile in the Diels–Alder Reaction : Relative Reactivities of the Olefinic and (Prof. G. J. Janz and N. E. Duncan), 933
*Cycloclypeus carpenteri* Brady : Nuclei of (Dr. Margaret W. Jepps), 1114
Cyrillic Script : Transliteration of, 548 ; (M. Aurousseau), 940
Cysts of the Potato Root Eelworm : Seasonal Fluctuations in the Degree of Hatching from (David W. Fenwick and Elizabeth Reid), 47
Cytochemistry, a Critical Approach (Prof. J. F. Danielli), *review* by Dr. Geoffrey H. Bourne, 1082
Cytochemistry : Trials and Tribulations of, *review* by Dr. Geoffrey H. Bourne, 1082
Cytochrome Oxidase : Controlling Effect of Salts on the Activity of the (Prof. H. Lundegårdh), 477
Cytochrome Oxidase and the 'Pasteur Enzyme' (Prof. D. Keilin and Dr. E. F. Hartree), 413
Cytochrome System : Reaction Kinetics of the (Prof. H. Lundegårdh), 521
Cytological Observations on Two Desmids : 'Diffuse' Centromere, and other (G. C. King), 181
Cytology : International Review of (edited by G. H. Bourne and J. F. Danielli), Vol. 1, *review* by Dr. E. N. Willmer, 52
    Progress in, *review* by Dr. E. N. Willmer, 52
Cytology of the *Dryopteris spinulosa* Complex in Eastern North America (Prof. I. Manton and S. Walker), 1116
Cytoplasmic Double Membranes : Electron Microscopy of Mitochondria and (Dr. Fritiof S. Sjostrand), 30
Cytoplasmic Localization of Nucleic Acids in Plant Cells (J. Chayen and K. P. Norris), 472
Cytoplasmic Particles in Bean Root Cells (Dr. E. Robinson and R. Brown), 313 ; (G. L. Brown, S. Fitton Jackson and J. Chayen), 1113

DAMPING of Turbulence by a Magnetic Field (W. Murgatroyd), 217
Dances in the Christian Church and in Popular Medicine : Religious (Prof. E. Louis Backman), translated by E. Classen, *review* by M. C. Burkitt, 667
Dancing in Religion : The Place of, *review* by M. C. Burkitt, 667
*Daphnia* : Influence of Temperature and Iron on Hæmoglobin Synthesis by (Prof. H. Munro Fox, Elizabeth A. Phear and Barbara M. Gilchrist), 347
*Datura innoxia* : Alkaloids of (W. C. Evans and Dr. M. W. Partridge), 656
DDT : Adsorption of, on Suspended Solids in River Water and its Role in Black-fly Control (F. J. H. Fredeen, A. P. Arnason and B. Berck), 700
DDT and BHC : Effects of, on Soil Arthropods (J. G. Sheals), 978
Decarboxylation of Collagen (Dr. Robert L. Sykes), 654
Decarboxylation of Oxalo-Acetic Acid : Metal Ion Catalysis of the (Dr. R. J. P. Williams), 304
Decomposition of Ethyl Nitrate : Effect of Nitric Oxide on the Thermal (Dr. F. H. Pollard, H. S. B. Marshall and A. E. Pedler), 1154
Decomposition of Litter ; Microbiological (Prof. Jan Smit and Dr. K. T. Wieringa), 794
Decontamination (Radiological) Ion-exchanging Surfaces in (E. W. Jackson and Miss L. Garrard), 442
Deep-Sea Floor and the History of the Earth (International Joint Commission on Oceanography of the International Council of Scientific Unions Symposium on), 1054
Deep-Sea Investigations : Magnetic Measurements in—Construction of Non-magnetic Containers (Dr. Niels Arley, Børge Lunn, Max Nielsen and Carl Nørgaard), 383 ; Magnetic Investigations on the *Galathea* Expedition (Dr. Niels Arley, Povl Andreasen, Jørgen Espersen and Johannes Olsen), 384
Deep-Sea Sediments : Ionium Determination in (Mlle. N. Isaac and Dr. E. Picciotto), 742
    Vertical Distribution of Radium in (Dr. Viktor St. Kroll), 742
Deep-Sea Trawling (Dr. O. Nybelin), 595
Deformation : Preparation of Single Crystals of Titanium and their Mode of (Dr. A. T. Churchman), 706
Deformation in Metals : A Dislocation Model for the Study of Boundary Phenomena and (W. I. Pumphrey), 218
Deformation and Flow in Biological Systems (edited by Prof. A. Frey-Wyssling), *review* by D. R. Wilkie, 53
Degradation of Methionine by Hydrogen Peroxide (Yoshihiko Matsuo), 1021
Degradation of Polypeptides from the Carboxyl End Stepwise (R. A. Boissonnas), 304
Degradation of Polystyrene : Thermal (Paul D. Zemany), 391
Degradation of Sugars on Ion-Exchange Columns of 'Amberlite IRA 400 (OH′)', (J. D. Phillips and Dr. A. Pollard), 41
Degradation of Wool by Diazomethane Solutions . Apparent (I. J. O'Donnell and Dr. J. M. Swan), 571
Dehydrogenase (Succinic) : Histochemistry of (Dr. H. A. Malaty and Dr. G. H. Bourne), 295
Dehydrogenation of various Substrates by *Vibrio choleræ* (A. Dudani, S. N. Iyer, C. R. Krishna Murti and D. L. Shrivastava), 81
Democracy : Mechanism of Government in a, 183
Density Distribution of Neutrons and Protons in Atomic Nuclei . Difference between the (Prof. P. Gombás), 979, *erratum*, 1054
Dentistry, Biology and the Social Sciences : Fellowships, Scholarships and Bursaries in (Nuffield Foundation), 246
Deodar as Pencil Wood (M. A. Rehman and Jai Kishen), 732
2-Deoxy-D-ribose . A New Synthesis of (Y. Matsushima and Y. Imanaga), 475
Deoxypentose Nucleic Acids : Molecular Structure of (Dr. M. H. F. Wilkins, Dr. A. R. Stokes and H. R. Wilson), 738
Deoxyribonucleic Acid : Genetical Implications of the Structure of (J. D. Watson and F. H. C. Crick), 964
Deoxyribonucleic Acid Irradiated with X-Rays : 'After-effect' in Aqueous Solutions of (Malcolm Daniels, Dr. George Scholes and Dr. Joseph Weiss), 1153
Deoxyribose Nucleic Acid A Structure for (J. D. Watson and F. H. C. Crick), 737
Depopulation and Rural Life in Aberdeen (Bertram Hutchinson), 643
Depopulation and Rural Life in Scotland, 643
Depopulation and Rural Life in the Solway Counties (Bertram Hutchinson), 643
Depopulation and Rural Life in the Tweed Valley (Bertram Hutchinson), 643
Depressant of Primary Inhibition : Strychnine as a (K. Bradley and Prof. J. C. Eccles), 1061
Desiccation : Recovery of Caprinized and Lapinized Rinderpest Viruses from Condensed Water Vapour removed during (A. L. C. Thorne), 609
Desmids . 'Diffuse' Centromere, and other Cytological Observations on Two (G. C. King), 181
Detergents (Synthetic) . Committee on the Effects of, 912
Determinant of Conductivity in a Low-frequency Electric Discharge : Langmuir Adsorption as a (A. P. Saxena, M. G. Bhatawdekar and N. A. Ramaiah), 929
Determination of Creatinine by the Jaffé Reaction (Dr. G. R. Hervey), 1125
Determination of the Relative Electrode Potential of an Uncharged Metal in Solution (Dr. J. O'M. Bockris and R. Parry-Jones), 930
Development by the Ministry of Supply : Increased Expenditure for Research and, 288
Development of the Sea Urchin : Somatic Reduction Division in the (Prof. Per Eric Lindahl), 437
Development and Man-power Problems : Overseas, 405
Dextran : Photo-insolubilization of (F. G. Pautard), 302
Dextrans in Aqueous Solution : Molecular Configuration of (Dr. A. G. Ogston and E. F. Woods), 221
3 : 5-Di-iodo-Tyrosine : Artefacts produced from 3-Iodo-Tyrosine and, by Heating with Alkali (P. G. Stanley), 933
Diabetogenic Effect of Nucleic Acid (Dr. Z. Brada), 524
Diacetyldeoxycholate : Adsorption and Hæmolytic Action of (Dr. R. Croes and R. Ruyssen), 846
*Diadema* : Light Emission and Light Perception in Species of (Prof. N. Millott), 973
Diazomethane Solutions : Apparent Degradation of Wool by (I. J. O'Donnell and Dr. J. M. Swan), 571
Dichloropropene Dichloropropane Soil Fumigant : Tainting of Tobacco by a (R. McChlery), 578
Dictionary of Scientific and Technical Words : An Explaining and Pronouncing (Dr. W. E. Flood and Dr. Michael West), *review* by W. L. Sumner, 993
Dielectric Reflecting Films : Multi-layer, at Wave-lengths between 4000 and 4600 A. (J. Ring and Dr. W. L. Wilcock), 648
Dielectric Relaxation Time of Polar Molecules in Solution (Nora E. Hill), 836
Dielectric Strength (High) : Negative-Ion Formation in Gases of (Dr. J. W. Warren, J. Marriott and Dr. J. D. Craggs), 514
Diels–Alder Reaction : Relative Reactivities of the Olefinic and Cyano Links of Acrylonitrile in the (Prof. G. J. Janz and N. E. Duncan), 933
Dietary Penicillin Effect of, on Blood Composition and Œstrogen-induced Oviduct Growth in the Folic-Acid Deficient Chick (W. O. Brown), 845
Differential Fluorescence in Identification of Tobacco Trashy Leaf (R. Johanson), 753
Differential Thermal Analysis : Bibliography of (Prof. W. J. Smothers, Y. Chiang and A. Wilson), 244
Diffraction (Electron) . Investigation of Nuclear Motion by (L. S. Bartell and Prof. L. O. Brockway), 978
Diffraction (X-Ray) . Fortieth Anniversary of the Discovery of (J. Thewlis), 106
Diffraction of Bone . Low-Angle X-Ray (Prof. A. Engstrom and J. B. Finean), 564

Diffraction Data : A.S.T.M. Index of X-Ray Powder (American Society for Testing Materials), 155
Diffraction Study : Electron, of the Hydrogen Bonds in Boric Acid (Dr. J. M. Cowley), 440
  X-Ray, of the Transformation of Retained Austenite by Fracture (L. W. Pateman and H. S. Peiser), 696
'Diffuse' Centromere, and other Cytological Observations on Two Desmids (G. C. King), 181
Diffusion (Activated) : Measurement of, of Adsorbed Molecules (R. A. W. Haul), 519
Diffusion of Silicon in Ferrite (F. J. Bradshaw, G. Hoyle and K. Speight), 488
Digestion of Plasmatic Proteins with Pepsin : Anti-diuretic and Oxytocic Substances liberated by the (Prof. H. Croxatto, L. Barnafi, G. Rojas, A. Reyes and A. Infante), 82
Digital Calculating Machinery : Proceedings of a Second Symposium on Large-Scale (jointly sponsored by the Navy Department, Bureau of Ordnance and Harvard University), *review* by Dr. M. V. Wilkes, 54
Digital Computers : Electronic (American Institute of Electrical Engineers and the Institute of Radio Engineers Conference on), 599
9 : 10-Dihydroxystearic Acids and their Acyl Derivatives . Estimation of the (Dr. G. King), 566
1 : 3-Diketo-2-phenyl-5-bromoindan : Thermochromism and Keto-Enol Tautomerism of Solutions of (Prof. A. Schönberg, Dr. A. Mustafa and Dr. W. Asker), 222
Diploid Embryos of *Habrobracon* : Effects of Methyl *bis* (beta-Chloroethyl) Amine Hydrochloride on Haploid and (A. M. Clark and W. C. Besser, Jun.), 178
Dipole Moments of Metal Oleates (A. Gillmour, S. M. Nelson and Dr. R. C. Pink), 1075
Dipping Technique : Colour Reactions on Paper Chromatograms by a (Ivor Smith), 43
D. C. Analogue Computers, *review* by Dr. M. V. Wilkes, 1132
Direct-Reading Emission Spectroscopy, 596
Direction : Travelling Disturbances in the Ionosphere—Diurnal Variation of (G. H. Munro), 693
Directivity of Solar Radio Emission from Sunspots A Method of Analysis of the (T. Takakura), 445
Discharges : Ionization Phenomena in (Clarendon Laboratory, the Institute of Physics, the Physical Society and the British Electrical and Allied Industries Research Association Conference on), 463
Discovery of X-Ray Diffraction : Fortieth Anniversary of the (J. Thewlis), 106
Diseases (Plant Pests and) : Assessment of (Association of Applied Biologists Symposium on), 553
Diseases of the Blood : Grants, Scholarships and Fellowships for Research on (Lady Tata Memorial Fund), 246
Dislocation Model for the Study of Boundary Phenomena and Deformation in Metals (W. I. Pumphrey), 218
Dislocations : Etch-pits and (R. Gevers), 171
Dislocations and the Theory of Solids (Prof. N. F. Mott), 234
Disorder in Vitreous Materials : Internal Stresses caused by (H. Rawson), 169
Dispersions : Colloidal (Earl K. Fischer), *review* by Dr. A. S. C. Lawrence, 142
Dissociation of Cells from Chick Embryos : Experimental (Dr. Sivatosh Mookerjee), 796
Dissociation of Insulin : Reversible (Eugène Fredericq), 570
Dissociative Chemisorption of Carbon Dioxide on Solid Catalysts (Prof. T. Kwan and Y. Fujita), 705
Distillation of some Organic Substances : Fractionation of Isotopes by (P. Baertschi, Prof. W. Kuhn and H. Kuhn), 1018
Distribution . Vertical, of Radium in Deep-Sea Sediments (Dr. Viktor St. Kroll), 742
  Vertical, of *Teredo norvegica* (G. Owen), 484
Distribution of Animals and Plants in Africa : Problems of (Linnean Society of London Discussion on), 639
Disulphide Interchange Reaction (Dr. F. Sanger), 1025
Ditetrazolium Chloride . Histochemical Detection with, of some Enzymatic Activities in Isolated Mitochondria (Dr. Mario Umberto Dianzani), 125
Diurnal Variation of Direction : Travelling Disturbances in the Ionosphere —(G. H. Munro), 693
Division : Somatic Reduction, in the Development of the Sea Urchin (Prof. Per Eric Lindahl), 437
Dizygotic Twin Lambs : Intolerance of, to Skin Homografts (G. H. Lampkin), 973
Dogger Bank Area : Change in the Composition of the Bottom Fauna of the (L. Birkett), 265
Dominion Civil Service Fellowships, 777
Dominion and Colonial Exhibitions (Trinity College, Cambridge), 377
Dosimetry : Chemical, at High Dose-rates (Dr. N. Miller), 688
Dosimetry (Chemical) : Use of Tracers in (Gosta Rudstam and Prof. The Svedberg), 648
Dragonfly Nymphs : 'Giant' Fibres in (Dr. G. M. Hughes), 87
Drawing Synthetic Fibres (I. Marshall and A. B. Thompson), 38
Dreams and Imitation in Childhood : Play, (Prof. Jean Piaget), translated by C. Gattegno and F. M. Hodgson, *review* by Prof. John Cohen, 450
Dronning Maud Land, Antarctica : Measurements of Ice Thickness in (G. de Q. Robin), 55
Droplets : Oscillating (J. B. Lewis and H. R. C. Pratt), 1155
*Drosophila* Males treated with Mustard Gas : Chromosomal Re-arrangements in the Progeny of (Dr. M. Mehtab), 262
*Drosophila polymorpha* : A Further Analysis of the Polymorphism of (A. Brito da Cunha), 887
Drug Resistance in Bacteria : Origin of Acquired (Prof. John Yudkin), 541
Drugs (Cholinesterases and the Anti-cholinesterase) . Bibliography on (Dr. K.-B. Augustinsson), 729
Dry Rot in Wood (K. St. G. Cartwright and Dr. W. P. K. Findlay), fifth edition, 1053
Drying of Hides and Skins (J. R. Furlong), 294
*Dryopteris spinulosa* Complex in Eastern North America : Cytology of the (Prof. I. Manton and S. Walker), 1116
Du Pont, the Autobiography of an American Enterprise, *review*, 993
*Duboisia myoporoides* R. Br. . Occurrence of Nicotine together with Hyoscine in (K. Loftus Hills, W. Bottomley and P. L. Mortimer), 435
Dug-out Canoe in use in Vendaland (Dr. A. C. Hoffman), 867
Duns, Spinners and Sedges, *review* by Prof. J. W. Munro, 320
Dust (Coal) : Microscopical Identification of the Constituents of (Dr. R. G. H. B. Boddy), 928
Dutch Agriculture : Water Problems in, 19
Dyes : Uptake of, into Cut Leaves (Arwyn Charles), 435
Dyes (Polyhaptenic) : Non-specific Precipitation of Proteins by (Dr. John L. Morrison), 346
Dyestuffs Industry : The British, 916
Dynamic Potentials of Freshly Formed Liquid Surfaces (Dr. C. C. Addison and D. Litherland), 393

EARTH : The (Dr. Harold Jeffreys), third edition, *review* by Prof. B. Gutenberg, 408
  Deep-Sea Floor and the History of the (International Joint Commission on Oceanography of the International Council of Scientific Unions Symposium on), 1054
  The Origin of the (Prof. W. M. Smart), *review* by Prof. W. M. H. Greaves, 3
  Physics of the, *review* by Prof. B. Gutenberg, 408
  Temperature of the Interior of the (Prof. J. A. Jacobs), 835
Earth's Core : Earthquake Waves reflected at the (R. A. Garrick), 506
Earthquake of March 18 . The Turkish (Ernest Tillotson), 557
Earthquake Waves reflected at the Earth's Core (R. A. Garrick), 506
Earthquakes during 1952 (Ernest Tillotson), 732
East Africa : Miocene Anthracotheriidae from (D. G. MacInnes), 505
  Miocene Lemuroids of (Prof. W. E. Le Gros Clark and D. P. Thomas), 505
  Occurrence of *Puccinia polysora* Underw. in (R. M. Nattrass), 527
Eclipse of the Sun on June 30, 1954 Total, 505
Ecological Animal Geography (Prof. W. C. Allee and Karl P. Schmidt), second edition, *review* by Charles Elton, 761
Econometrics (Prof. Gerhard Tintner), *review* by Prof. M. G. Kendall, 275
Economics : Can, become an Exact Science ?, *review* by Prof. M. G. Kendall, 275
Economics of the Protection of Plants, *review* by Dr. I. Thomas, 665
Eddington Medal of the Royal Astronomical Society awarded to Canon G. Lemaître, 108
EDSAC : A New Application of, to Crystal Structure Analysis (W. Cochran and A. S. Douglas), 1112
Education : Adult, in Great Britain, 759
  Adult, at Leeds, 548
  African, a Study of Educational Policy and Practice in British Tropical Africa (produced on behalf of the Nuffield Foundation and the Colonial Office), 1127, 1134
  Health (Cyril Bibby), *review* by Miss P. M. Taylor, 186
  Health, in Rumania (Dr. S. Leff), 728
  Higher Technological, in Britain, 242
  Museums and (Dr. D. A. Allan), 1004
  Technical and Technological, in Britain (C. L. Bott), 958
  Technological, in Britain, 1095
Education (Adult) : Appointment of a Committee on, 1095
  Role of Universities in, 805
  Universities in, 759
Education (African) : Stock-taking on (Olumbe Bassir), 1134
Education (Technical) : Basis of, 964
Education (Technological) : Function of, 533
  A Policy for (Association of Scientific Workers Report on), 109
Education (Technological and Technical) . Expansion of, 581
Education in Africa, 1127
Education in India, 733
Education in Chemistry (London Section of the British Association of Chemists and the London Section of the Royal Institute of Chemistry Discussion on), 156, 465
Education in a Technological Society (Unesco Tensions and Technology Series), 533, 964
Educational Grants for Training in Plastics (Plastics Industry Education Fund), 200
Eel : A Freshwater, on Zanzibar Island (Prof. J. L. B. Smith), 129
Eelworms (Root) (*Heterodera* spp.) : Hatching Responses in (F. G. W. Jones and R. D. Winslow), 478
Egg of the Garden Chafer, *Phyllopertha horticola* L. : Absorption of Water by the (Roger Laughlin), 577
Eggs (British Birds and) : Museum Collections of (Colin Matheson), 957
Eggs of the Fruit Tree Red Spider Mite, *Metatetranychus ulmi* (Koch) : Toxicity of Chlorinated Phenyl Benzenesulphonates to Winter (Dr. A. H. M. Kirby and R. P. Tew), 479
Egypt ; Ancient (J. E. Manchip White), *review* by Miles Burkitt, 96
Egyptian Antiquities : Flinders Petrie Collection of (Exhibition in the Museum of Egyptology, University College, London), 914
Elastase : Elastin and (I. Banga and Prof. J. Baló), 44
Elasticity in Liquids (British Society of Rheology Symposium on), 778
Elastin and Elastase (I. Banga and Prof. J. Baló), 44
Electric Discharge (Low-frequency) . Langmuir Adsorption as a Determinant of Conductivity in a (A. P. Saxena, M. G. Bhatawdekar and N. A. Ramaiah), 929
Electric and Magnetic Shielding : High-frequency (Y. Asami and A. Matsumoto), 957 ; (T. Matsumoto), 957
Electrical Conductivity of certain Crystalline Materials after Grinding (J. S. Dryden and Dr. R. J. Meakins), 307
Electrical Devices for Controlling the Movements of Anadromous Fish, 591
Electrical Direct Heating Some Researches on High-Frequency Phenomena and, 957
Electrical Engineering Failures : Analysis of Mechanical and (Prof. F. C. Thompson), 510
Electrical Properties of Anodized Aluminium : Effects of Water Vapour on the (Dr. F. Ansbacher and Dr. A. C. Jason), 177
Electrical Resistance of Fibre Bundles . A Method of Determining the (G. Morris and A. N. D. Young), 220
Electrical Resistivity of Metals : Lattice Defects and the (T. Broom), 1104
Electrical Units : A Theoretical and Practical Approach to the Teaching in the M. K. S. System of (F. A. Meier), 779
Electrification . Static (Institute of Physics Conference on), 20
Electrification (Rural) : Research in—Work at the Electrical Research Association, 1103
Electrification of Polar Polymers : Frictional (J. A. Medley), 1077

Electroacoustics · International Congress on, 776
Electrode Potential (Relative) · Determination of the, of an Uncharged Metal in Solution (Dr. J. O'M. Bockris and R. Parry-Jones), 930
Electrodes (Towed) : Measurement of Wind Currents in the Sea by the Method of (K. F. Bowden), 735
Electrodynamics : The New Classical (Prof. M. Avramy Melvin), 890
Electrolytes (Colloidal) : Moving-Boundary Electrophoresis of, using Concentration Boundaries (Dr. Hira Lal), 175
Electrolytic Polishing of Lead in a Sodium Acetate–Acetic Acid Bath (Elizabeth Jones and H. R. Thirsk), 843
Electron Diffraction · Investigation of Nuclear Motion by (L. S. Bartell and Prof. L. O. Brockway), 978
Electron Diffraction Study of the Hydrogen Bonds in Boric Acid (Dr. J. M. Cowley), 440
Electron Microscope : Action of Antibiotics on Avian Tubercle Bacilli studied with the (E. M. Brieger, Dr. V. E. Cosslett and Audrey M. Glauert), 211
  Determinations of Size of Particles with the (E. Atherton), 350
  Summer Laboratory Course in Techniques and Applications of the (Cornell University), 729
Electron Microscope and Microdissection (R. Bovey), 155
Electron Microscope Specimen Support Films . A New Method of making (D. E. Bradley), 1076
Electron Microscope Studies of the Structure of the Influenza Virus (L. Hoyle, Dr. R. Reed and Prof. W. T. Astbury), 256
Electron Microscopy of Mitochondria and Cytoplasmic Double Membranes (Dr. Fritiof S. Sjostrand), 30
Electron Microscopy of Plant Cilia (Prof. I. Manton, B. Clarke, A. D. Greenwood and E. A. Flint), 289
Electron Multiplication Process : A New (W. L. Harries and Dr. A. von Engel), 517
Electron Optics · Recent Research on (Physical Society Discussion on), 596
Electron-Density Distribution in Crystals : Calculation of, with the Help of Convolution Operations (R. Hosemann and S. N. Bagchi), 785
Electronic Analog Computers (D–C Analog Computers), (Dr. Granino A. Korn and Theresa M. Korn), *review* by Dr. M. V. Wilkes, 1132
Electronic Computing and Control Circuits : Synthesis of (Staff of the Computation Laboratory of Harvard University), *review* by Dr. M. V. Wilkes, 453
Electronic Devices : Eighth Annual Exhibition of (North-Western Branch of the Institution of Electronics), 822
Electronic Digital Computers (American Institute of Electrical Engineers and the Institute of Radio Engineers Conference on), 599
Electronic Instruments in Atomic Energy (Course at the Isotope School of the Atomic Energy Research Establishment), 290
Electronic Pump : Methods of obtaining High Vacuum by Ionization—Construction of an (Dr. Helmut Schwarz), 600
Electronically controlled Spectrographic Spark Source (Dr. Á. Bardócz), 1156
Electronics · Advances in (edited by L. Marton), Vols. 3 and 4, *review* by Dr. R. L. Smith-Rose, 897
  The Progress of, *review* by Dr. R. L. Smith-Rose, 897
  Research Fellowships in the field of (Massachusetts Institute of Technology), 377
Electrons for the Examination of Metals : The Use of (University of Cambridge in, co-operation with the Institute of Metals Summer School in), 867
Electrophoresis · Applications of, in studying New Antibiotics (N. Kelso King and Hazel M. Doery), 878
  Course on (Unesco Science Co-operation Office for Latin America), 1005
  Moving-Boundary, of Colloidal Electrolytes using Concentration Boundaries (Dr. Hira Lal), 175
  Paper, of Polyglutamyl Peptide (R. E. Strange and N. Harkness), 77
  Photoelectric Control of the Compensator in (Dr. R. L. Warren and Dr. P. A. Charlwood), 353
Electrophoresis (Paper) · Serological Activity of Globulin Fractions of Anti-D Sera separated by (Branislav D. Janković and Herman W. Krijnen), 982
Electropolishing Mechanism of (Dr. P. R. Rowland), 931
Electrostatic Single Lens permitting Rigorous Calculation (Dr. Peter Schiske), 443
Elephant : Serological Relationships of Hyrax and (Bernard Weitz), 261
Elimination of Chromatophores and Eyespot in *Euglena* : Experimental (E. G. and O. Pringsheim), 244
Embedding Brittle Specimens of Wood for Sectioning : A Method of (J. F. Levy), 984
Embedding of small Mineralized Plant Fossils Staining and Plastic (Dr. Henning Horn af Rantzien), 516
Embryo (Chicken) : Growth and Axon Formation in the Midbrain of the (Dr. R. J. O'Connor), 131
Embryology of Birds . Experimental, *review* by Prof. Nelson T. Spratt, jun., 141
Embryology of the Emperor Penguin (*Aptenodytes forsteri*), (T. W. Glenister), 357
Embryology of the Orobanchaceae (B. Tiagi), 728
*Embryology and Experimental Morphology, Journal of* (D. R. Newth), 339
Embryos (Chick) : Experimental Dissociation of Cells from (Dr. Sivatosh Mookerjee), 796
Emission of Molecular Complexes of Nitro-compounds (R. Foster and D. Ll. Hammick), 40
Emission Spectroscopic Determination of Metals in Non-Metallic Samples (American Association of Spectrographers Symposium on), 66
Emperor Penguin (*Aptenodytes forsteri*) : Embryology of the (T. W. Glenister), 357
Employment in an Ageing Population : Problems of, 623
Encapsulation in Rumen Bacterial Fractions (P. N. Hobson and Margaret J. MacPherson), 129
*Endeavour* Prizes for Science Essays (British Association for the Advancement of Science), 421
Endocrine Systems and their Psychological Effects . Chemistry and Inter-Relationships of (Society for Visiting Scientists Discussion on), 509
Endogenous Buds in *Ophioglossum vulgatum* L. (Prof. C. W. Wardlaw), 88
Energies (High) Acceleration of Heavy Ions to (Dr. D. Walker and Dr. J. H. Fremlin), 189
Energy Exchange Indirect Determination of Water Retention in Cattle as a means of estimating (K. L. Blaxter and J. A. F. Rook), 609
Energy Transport by Enzymic Reduction of 'Onium' Salts : Biosynthesis and (Dr D. W. Woolley), 323
Engineering Scholarships in Science and (National Research Council of Canada), 66
Engineering (Foundation) : Third International Conference on Soil Mechanics and, 245
Engineering in the University of Nottingham, 1099
Engineering Structures . Behaviour of (Prof. A. J. S. Pippard), 766, 867
England (Southern) · Humidity of the Upper Troposphere and Lower Stratosphere over (J. K. Bannon, R. Frith and H. C. Shellard), 381
England and Wales . Decennial Supplement for 1931 for the Census of, 549
English Course : An (Stanley Day and S. H. Wiltshire), *review* by W. L. Sumner, 587
English Flax · Sporulating Anaerobes on (Esther Hellinger), 1119
Enlightenment · The Philosophy of the (Ernst Cassirer), translated by Fritz C. A. Koelln and James P. Pettegrove, *review* by F. I. G. Rawlins, 900
Enolase : Interaction of Manganous Ions with (Dr. Bo G. Malmström), 392
Entomology · An Angler's (J. R. Harris), *review* by Prof. J. W. Munro, 320
Entwicklungsphysiologie (L. v. Ubisch), *review* by Prof. C. H. Waddington, 992
Environmental Variability in Quantitative Inheritance . Analysis of (E. C. R. Reeve and F. W. Robertson), 874
Enzymatic Activities in Isolated Mitochondria : Histochemical Detection with Ditetrazolium Chloride of some (Dr. Mario Umberto Dianzani), 125
Enzymatic Breakdown and Synthesis of Acetoacetate (Dr Joseph R. Stern, Dr. Minor J. Coon and Miss Alice Del Campillo), 28
Enzymatic Formation of Hydroxamic Acid : Effect of L-Glutamic Acid Analogues on the (N. Lichtenstein, Helen E. Ross and Prof. Philip P. Cohen), 45
Enzymatic Transoximation (Prof. Kazuo Yamafuji), 745
Enzyme' ('Pasteur') . Cytochrome Oxidase and the (Prof. D. Keilin and Dr. E. F. Hartree), 413
Q-Enzyme : A Simple Method for the Preparation of Crystalline Potato Phosphorylase and (H. Baum and Dr. G. A. Gilbert), 983
Enzyme Preparations : Column Procedures for the Salt Fractionation of (Sigmund Schwimmer), 442
Enzymes : Activation of, by Chelating Agents (S. M. Altmann and Dr. E. M. Crook), 76
Enzymes (Proteolytic) : Possible Role of, in Protein Synthesis (Robert B. Loftfield, John W. Grover and Mary L. Stephenson), 1024
Enzymes in Cells : The Function and Location of (Royal Society Discussion on), 815
Enzymic Reduction of 'Onium' Salts : Biosynthesis and Energy Transport by (Dr. D. W. Woolley), 323
Enzymic Systems in Root Apices (E. Robinson and R. Brown), 636
Eosinophils in Rats : Influence of Trypan Blue on the Number of Circulating (Dr. Ines Wesley), 266
Epicuticle of Insects : Homology of the Layers of the (Prof. R. Dennell and Dr. S. R. A. Malek), 298
Epidermis (Mouse) · Latent Carcinogenic Action of Beta-Irradiation on (Dr. Philippe Shubik, A. Robert Goldfarb, A. C. Ritchie and Hermann Lisco), 934
Epigenetics of Birds (Prof. C. H. Waddington), *review* by Prof. Nelson T. Spratt, jun., 141
Equilibrium and Non-Equilibrium States · Summer Course in the Thermodynamics of the (Massachusetts Institute of Technology), 729
Equilibrium Properties of Solutions of Non-Electrolytes (Faraday Society General Discussion on), 462
Equine Osteodystrophia : Excess of Molybdenum in Herbage as a Possible Contributory Factor in (Dr. T. Walsh and Dr. L. B. O'Moore), 1166
Erythrocytes *in vivo*: Fixation of Bacterial Products by, and by Leucocytes (Stephen V. Boyden), 402
*Escherichia coli* : Anaerobic Growth of, in the Presence of certain Acids (G. A. Morrison), 937
*E. coli* Strains : Inhibition of, by Amino-Acids (D. Rowley), 80
Esterases : Hydrolysis of Anhydrides by (Prof. Felix Bergmann, Menachem Wurzel and Arela Shimoni), 744
Esters (Phosphate) : Detection of, on Paper Chromatograms (H. E. Wade and D. M. Morgan), 529
  Paper Chromatography of (E. Fletcher and Dr. F. H. Malpress), 838
État solide, Rapports et Discussions (Institut International de Physique Solvay, Neuvième Conseil de Physique tenu à l'Université Libre de Bruxelles du 25 au 29 septembre 1951), *review* by Dr. B. A. Bilby, 991
Etch-pits and Dislocations (R. Gevers), 171
Ethanol Solution · Kinetics of Reaction in, from —80° C. to + 20° C. (Dr. E. F. Caldin, G. Long and F. W. Trowse), 1124
Ethyl Chlorophyllides : Absorption Spectra of the (W. F. Watson), 842
Ethyl Nitrate Effect of Nitric Oxide on the Thermal Decomposition of (Dr. F. H. Pollard, H. S. B. Marshall and A. E. Pedler), 1154
*Eucalyptus citriodora* Hooker . Physiological Forms of (A. R. Penfold and J. L. Willis), 883
*Eucalyptus regnans* Wood : Identification of 4-Methyl-D-glucuronic Acid in (C. M. Stewart and D. H. Foster), 792
*Eugenia aromatica* : Sudden-Death Disease of the Clove Tree (Dr. P. J. Nutman and F. M. Roberts), 128
*Euglena* Experimental Elimination of Chromatophores and Eyespot in (E. G. and O. Pringsheim), 244
Europe Aid for Biological Research in (New York Zoological Society), 638
  An American in, the Life of Benjamin Thompson, Count Rumford (Egon Larsen), *review* by T. Martin, 947
Europe since 1939 . Population Changes in (Gregory Frumkin), *review* by H. Silcock, 494
Europium · Activation of Lithium Iodide by (Dr. James Schenck), 518
Everest, 1051
Evolution : Organic (National Institute of Sciences of India Conference on), 637
  The Role of the South Atlantic in Biogeography and (Society for the Study of Evolution Symposium on, Proceedings), 669
  A Textbook of (Prof. Edward O. Dodson), *review*, 188
Evolution of the ζ Persei Group of O- and B-Type Stars · Age and (A. Blaauw), 1005

Evolutionary Implications: A Possible New Principle in Taxonomy, and its (R. A. Crowson), 883
Ewe's Oviduct: Mucin Secretion in the (Dr. R. Hadek), 750
Examination Question: From, to Industrial Problem (J. F. Hinsley), 779
Exercise (Enforced): Effect of, on Myoglobin Concentration in Muscle (Dr. R. A. Lawrie), 1069
Expenditure: Increased, for Research and Development by the Ministry of Supply, 288
Experiment: The Logic of (Dr. J. Bronowski), 194
Experimental Physics in University College, Dublin, 287
Exploring the Sea (Royal Geographical Society and the National Institute of Oceanography Exhibition), 65
Explosion in Liquids and Solids: Initiation and Growth of (F. P. Bowden and A. D. Yoffe), *review* by Dr. James Taylor, 186
Explosions: Birth and Growth of, *review* by Dr. James Taylor, 186
Extension Growth of Root and Shoot Segments of *Pisum sativum*: Effects of Trichloroacetic Acid on the (Sen Gita and E. K. Woodford), 936
Extra-Cellular Photosynthetic Reactions in Entire Leaf Macerates (Dr. F. C. Gerretsen), 207
Extra-mural Function of Universities (Thomas Kelly), 776
Extraction of Radioiodide from Urine: A Rapid Method for the (D. G. Arnott and J. Wells-Cole), 269
Exudation of Material from Slip Bands at the Surface of Fatigued Crystals of an Aluminium-Copper Alloy (P. J. E. Forsyth), 172
Eyes of Trout: A New Trematode Metacercaria from the (Dr. M. B. Lal), 130
Eyespot in *Euglena*: Experimental Elimination of Chromatophores and (E. G. and O. Pringsheim), 244

$F_2$-Region Ionospheric Storms: Geo-Morphology of (Dr. D. F. Martyn), 14
'Facilitation' at a Single Nerve-Muscle Junction: Statistical Nature of (Dr. J. del Castillo and Prof. B. Katz), 1016
Fakes and Forgeries in Museums (Dr. H. J. Plenderleith), 18
Far Eastern Prehistoric Congress: Fourth, 913
Faraday Medal of the Institution of Electrical Engineers awarded to Sir Stanley Angwin, 287
Farm Weeds Illustrated: Common (Plant Protection, Ltd.), *review* by L. J. F. Brimble, 666
*Fasciola gigantica* Cobbold 1856: Life-history of (Dr. S. Brian Kendall and J. W. Parfitt), 1165
'Father of Australia': Sir Joseph Banks, The, *review* by Dr. Charles Singer, 449
Fatigued Crystals of an Aluminium-Copper Alloy: Exudation of Material from Slip Bands at the Surface of (P. J. E. Forsyth), 172
Fats: Oxidation of Oils and (Oils and Fats Group of the Society of Chemical Industry Symposium on), 678; (Prof. C. E. H. Bawn), 1057
Fatty Acids: Role of Choline in the Oxidation of, by the Isolated Liver (Camillo Artom), 347
Fatty Acids (Rape-oil): Urea Complexes of (J. H. Skellon and C. G. Taylor), 266
Fatty Materials: A Stain for some (R. H. Harris), 332
Fauna (Bottom): Change in the Composition of the, of the Dogger Bank Area (L. Birkett), 265
Fauna of South Carolina: Flora and, 677
Faune de France, 56, Orthoptéroides (Prof. Lucien Chopard), *review* by David R. Ragge, 626
Feeding of Seaweed Meal to Lactating Cows (Dr. George Dunlop), 439
Feeding Mechanisms of a Deep-Sea Fish *Chauliodus sloani* Schneider (the late Dr. V. V. Tchernavin), 1096
Feldspar Minerals: Investigation at Cambridge of the, 636
Fellowship: Gerontological Research (Nuffield Foundation), 462
Fellowships: Colonial Civil Service, 777
  Dominion Civil Service, 777
  Home Civil Service (Commonwealth Fund), 596
  Frank B. Jewett (American Telephone and Telegraph Co. Awards), 332
  Grants, Scholarships and, for research on Diseases of the Blood (Lady Tata Memorial Fund), 246
  Merck (National Research Council, Ottawa, Awards), 1054
  Research, in the field of Electronics (Massachusetts Institute of Technology), 377
  Research, at Government Scientific Establishments, 200
  Senior Research, and Scholarships (Lady Tata Memorial Trust Awards), 1098
Fellowships for Chemical Research: Ramsay Memorial, 421
Fellowships in Clinical Research (Medical Research Council), 20
Fellowships for Medical Research: Beit Memorial (Awards), 1097
Fellowships in Medicine: Eli Lilly Travelling (Medical Research Council), 111
  Rockefeller Travelling (Medical Research Council), 111
Fellowships in Ophthalmology and Otology: Alexander Pigott Wernher Memorial Travelling (Medical Research Council), 111
Fellowships for Study in the United States (Commonwealth Fund), 596, 776
Fellowships in Tuberculosis: Dorothy Temple Cross Research (Medical Research Council), 111
Fellowships, Scholarships and Bursaries in Dentistry, Biology and the Social Sciences (Nuffield Foundation), 246
Fermentation Solutions: Determination of Glycerol in—a Rapid Chromatographic Procedure (A. F. Williams), 655
Fermentative Phases: Relationship between the Oxidative and, during Adaptation to Galactose in *Saccharomyces cerevisiae* (Dr. A. Leonard Sheffner), 1073
Ferns, Fungi, Trees: Wild Flowers, Grasses, (H. Trevor Jones), *review* by T. H. H., 143
Ferric Ion in Aqueous Solution: Reduction of, by γ-Radiation (C. B. Amphlett), 690
Ferrier Lecture for 1953 of the Royal Society (Dr. F. M. R. Walshe), 290
Ferrite: Diffusion of Silicon in (F. J. Bradshaw, G. Hoyle and K. Speight), 488
Fertility (Male): Effects of Daily Irradiation by Fast Neutrons on (G. J. Neary, R. J. Munson and R. H. Mole), 256
Fertility and Sterility: First World Congress on, 245
Fibre Bundles: A Method of determining the Electrical Resistance of (G. Morris and A. N. D. Young), 220
Fibres: Alternating Soft, to Jute, *review* by Sir Geoffrey Evans, 535
  Drawing Synthetic (L. Marshall and A. B. Thompson), 38
  Jute Substitute (A. E. Hearer), *review* by Sir Geoffrey Evans, 535
  Nerve, in the Adrenal Cortex of the Rat (J. D. Lever), 882
Fibres (Nerve): Hyaluronidase as an Adjuvant to Methylene Blue in staining of (Ian A. McGregor), 1070
  Silver Impregnation of (A. Peters), 613
Fibres in Dragonfly Nymphs: 'Giant' (Dr. G. M. Hughes), 87
Fibres from Protein Monolayers: Formation of (Dr. J. Gordin Kaplan and M. J. Fraser), 559
Fibrils in the Cilia of the Green Algae: Number of (Prof. I. Manton), 485
Fibrin Serum Factor (Dr. Sidney Shulman), 606
Fibroma Viruses: Classification of Myxoma and (Prof. Frank Fenner), 562
Fibrous Proteins: β-Forms of, and Synthetic Polypeptides (Dr. C. H. Bamford, L. Brown, Dr. A. Elliott, W. E. Hanby and I. F. Trotter), 1149
'Field Resistance' of the Potato to *Phytophthora infestans* de Bary: Nature of (K. O. Muller and J. C. Haigh), 781
Filariasis in the Pacific: The Fight against (Sir Philip Manson-Bahr), 368
*Film, Science and*, Vol. 1, No. 4, 243
Films: A New Method of making Electron Microscope Specimen Support (D. E. Bradley), 1076
Films (Thin): Radiation Induced by Alpha-Particles in (Amos Norman, M. A. Greenfield and Paul M. Kratz), 487
Finances of Research Associations, 503
Fish: A Further Coelacanthid, 17
  Spontaneous Parthenogenesis in a (Dr. H. Spurway), 437
Fish (Anadromous): Electrical Devices for Controlling the Movements of, 591
Fish (Deep-Sea): The Feeding Mechanisms of a, *Chauliodus sloani* Schneider (the late Dr. V. V. Tchernavin), 1096
Fish Muscle: Ribose and the Maillard Reaction in (Dr. H. L. A. Tarr), 344
Fish Research: Humber Laboratory for, 159
Fish, Clouds and Weather: Shore Life, (H. Trevor Jones), *review* by T. H. H., 143
Fish-liver Oils (Cod and other): Occurrence of Vitamin E in (Dr. F. Brown), 790
Fisheries of Africa: Hydrobiology and Inland (Scientific Council of Africa South of the Sahara Symposium on), 291
Fisheries Research in British Colonies (F. S. Russell), 159
Flagella (Algal): Structure of (Prof. W. T. Astbury and Dr N. N. Saha), 280
Flames (Hydrogen): Resonance Radiation from, containing Alkali Metals (C. G. James and Dr. T. M. Sugden), 428
Flamsteed's Observatory, 374
Flavour Assessment (Food Group of the Society of Chemical Industry, the Biological Methods Group of the Society of Public Analysts and other Analytical Chemists, and the Biometric Society Symposium on), 724
Flax: Seed Health in (Prof. A. E. Muskett), 66
Flax (English): Sporulating Anaerobes on (Esther Hellinger), 1119
Flight: The Birth of (Lord Brabazon of Tara), 640
Flight-tone and Wing-stroke Frequency of Insects (Dr. C. F. A. Pantin), 225
Floor of the Atlantic Ocean (Royal Society Discussion on), 857
Flora: Garden, of Hardy Plants in France, *review* by Sir Edward Salisbury, 493
Flora (British): Study of the, during 1952 (J. E. Lousley), 335
Flora of the British Isles: The New (Clapham, Tutin and Warburg), (*Errata* slip for the first edition), 333
Flora and Fauna of South Carolina, 677
Flora and Vegetation of Ireland, *review* by Prof. P. W. Richards, 1085
Flore illustrée des Jardins et des Parcs (Dr. P. Fournier), *review* by Sir Edward Salisbury, 493
Floristic Relationships: American-Asian (Hui-Lin Li), 206
Flour: Interaction of Chlorine Dioxide with—Certain Chemical Aspects (Dr. T. Moran, Dr. J. Pace and E. E. McDermott), 103
Flour Beetle (Confused): A Simple Method for Sexing the (J. A. Hope), 265
Flow in Biological Systems: Deformation and (edited by Prof. A. Frey-Wyssling), *review* by D. R. Wilkie, 53
Flow Method for the Synthesis of 'Block' Copolymers (J. A. Hicks and Prof. H. W. Melville), 300
Flow and Fracture: Studies in Large Plastic (Prof. P. W. Bridgman), *review* by Prof. A. H. Cottrell, 1130
Flower Book for the Pocket (Prof. Macgregor Skene), second edition, *review*, 143
Flower Initiation in Unvernalized Embryos: Accelerating Effect of an Extract of Vernalized Embryos of Winter Rye on (O. N. Purvis and Prof. F. G. Gregory), 687
Flowers: Wild; Grasses, Ferns, Fungi, Trees, (H. Trevor Jones), *review* by T. H. H., 143
Fluid through a Tube: A Device for Counting Small Particles suspended in a (Dr. P. J. Crosland-Taylor), 37
Fluorometric Analysis of Urinary Steroids (Dr. M. Finkelstein), 254
Fluorescence: Differential, in Identification of Tobacco Trashy Leaf (R. Johanson), 753
Fluoroacetate Poisoning—Comparison of Synthetic Fluorocitric Acid with the Enzymically Synthesized Fluorotricarboxylic Acid (Sir Rudolph Peters, R. W. Wakelin, D. E. A. Rivett and L. C. Thomas), 1111
Fluorocitric Acid (Synthetic): Fluoroacetate Poisoning—Comparison of, with the Enzymically Synthesized Fluorotricarboxylic Acid (Sir Rudolph Peters, R. W. Wakelin, D. E. A. Rivett and L. C. Thomas), 1111
Fluorosis and Pollution, 1097
Fluorotricarboxylic Acid (Synthesized): Fluoroacetate Poisoning—Comparison of Synthetic Fluorocitric Acid with the Enzymically (Sir Rudolph Peters, R. W. Wakelin, D. E. A. Rivett and L. C. Thomas), 1111
Foam: Sea (Miss E. M. Moore), 913
Focusing Principle: A New, applied to the Proton Linear Accelerator (J. S. Bell), 167
Foetal Adrenals and Aortic Bodies (Human): Determination of Adrenalin and Noradrenalin in the (Kalevi Niemineva and Aimo Pekkarinen), 436
Fog Fever Syndrome in Parasitic Bronchitis (J. F. Michel), 940
Folic-Acid Deficient Chick: Effect of Dietary Penicillin on Blood Composition and Œstrogen-Induced Oviduct Growth in the (W. O. Brown), 845

Follicle Development in the Australian Merino (P. G. Schinckel), 310
Food : Science Applied to, *review* by Dr. E. B. Hughes, 898
Food Consumption and Expenditure : Domestic, 1950, with a Supplement on Food Expenditure by Urban Working-Class Households, 1940–1949 (Annual Report of the National Food Survey Committee) (Ministry of Food), 426
Food Industries in India : Food and Population and Development of, *review* by Sir John Russell, 1038
Food Problems : India's, *review* by Sir John Russell, 1038
Food Products from Plants (Dr. A. E. Bender), 917, *errata*, 1099
Food Resources : Geography and (Association of Agriculture Course on), 777
Food Science (edited by Dr. E. C. Bate-Smith and T. N. Morris), *review* by Dr. E. B. Hughes, 898
Food Supply : The Problem of Future World (Nutrition Panel of the Food Group of the Society of Chemical Industry Meeting on), 160
Food and Population and Development of Food Industries in India, *review* by Sir John Russell, 1038
Foodstuffs : Newer Sources of (Nutrition Panel of the Society of Chemical Industry Discussion on), 917, *errata*, 1098
Foot in the Lucinacea (Eulamellibranchia) : Function of the (J. A. Allen), 1117
Forest Research : Statistical Methods in (J. N. R. Jeffers), 511
Forest Seeds in Sweden : Study of, 419
Forestry Research and Organization, 511
Forestry Research Stations in the British Commonwealth, 1952 : Gazetteer of Agricultural and, *review* by H. G. C., 54
Forests : Britain's—Thornthwaite, 557
  Organization of Sustained Yield in previously Unmanaged (N. V. Brasnett), 511
Forgeries in Museums : Fakes and (Dr. H. J. Plenderleith), 18
Formation *in vitro* of Melanin : Effects of some Chelate Compounds upon the (Saburo Isaka and Shuzo Ishida), 303
Fossil Hominoid Material collected by the British-Kenya Miocene Expedition (Prof. W. E. Le Gros Clark), 18
Fossil Mammals of Africa, No. 4, Miocene Anthracotheriidae from East Africa (D. G. MacInnes), 505 ; No. 5, The Miocene Lemuroids of East Africa (Prof. W. E. Le Gros Clark and D. P. Thomas), 505
Fossils (Mineralized Plant) : Staining and Plastic Embedding of small (Dr. Henning Horn af Rantzien), 316
Fouling of Ships : Gregariousness in Barnacles in relation to the, and to Anti-Fouling Research (Dr. E. W. Knight-Jones and Dr. D. J. Crisp), 1109
Foundation Engineering : Third International Conference on Soil Mechanics and, 245
Founder's Medal of the Royal Geographical Society awarded to P. D. Baird, 635
Fountains in Trafalgar Square, some Reflections on the Civil Service (C. K. Munro), *review* by R. Brightman, 362
Fourier Refinements : A 'Zero' Synthesis for (Andrew D. Booth), 168
Fourier Synthesis of Crystal Structure, *review* by Dr. C. H. Carlisle, 1131
Fouriersynthese von Kristallen und ihre Anwendung in der Chemie (Prof. Werner Nowacki), *review* by Dr. C. H. Carlisle, 1131
Fractionation of Isotopes by Distillation of some Organic Substances (P. Baertschi, Prof. W. Kuhn and H. Kuhn), 1018
Fracture : Studies in Large Plastic Flow and (Prof. P. W. Bridgman), *review* by Prof. A. H. Cottrell, 1130
  An X-Ray Diffraction Study of the Transformation of Retained Austenite by (L. W. Pateman and H. S. Peiser), 696
France : Faune de, 56, Orthoptéroides (Prof. Lucien Chopard), *review* by David R. Ragge, 626
  Garden Flora of Hardy Plants in, *review* by Sir Edward Salisbury, 493
  Orthopteroid Insects of, *review* by David R. Ragge, 626
Free-Energy of Solid Paraffin Wax : Surface (E. B. Greenhill and S. R. McDonald), 37
Freedom : Resources for (A Report to the President by the President's Materials Policy Commission), Vol. 1, Foundations for Growth and Security, Vol. 4, The Promise of Technology, 1
Freeze-drying Apparatus using the Principle of Short-path Sublimation : A Simple Tissue (Dr. L. O. Butler and Dr. L. G. E. Bell), 971
French Government Exchange Scholarships in Medical Science (Medical Research Council), 111
Freshwater Eel on Zanzibar Island (Prof. J. L. B. Smith), 129
Freshwater Science : Grants for Research in Marine or (Development Commission), 729
Friction : The Laws of (Dr. H. G. Howell), 220
Frictional Electrification of Polar Polymers (J. A. Medley), 1077
Frog (*Rana temporaria*) : Action of Insulin on the (C. L. Smith), 311
Frozen Terrains : Reflection Coefficient of Radio Waves from (J. R. Garlick), 259
Fructifications associated with Mycorrhizal Strawberry Roots (Barbara Mosse), 974
Fructose : Radioactive Starch, Glucose and, from Tobacco Leaves (H. K. Porter and R. V. Martin), 505
Fruit Tree Red Spider Mite (*Metatetranychus ulmi* (Koch)) : Toxicity of Chlorinated Phenyl Benzenesulphonates to the Winter Eggs of the (Dr. A. H. M. Kirby and R. P. Tew), 479
Fubini (Guido) Prize in Mathematics, 245
Fuel Particles (Solid) : Rates of Combustion of (G. A. E. Godsave), 86
Fuel Technology at Sheffield, 819
Fuel and Oil Industry : Some Applications of Physics in the (Dr. H. G. Nisbet), 779
Fumagillin : Effect of, upon *Nosema apis* (Zander), (Dr. L. Bailey), 212
Functional Relations of the Adenohypophysis and the Hypothalamus (A. P. D. Thomson and Prof. S. Zuckerman), 970
Functions of a Real Variable : The Theory of (Prof. R. L. Jeffery), *review* by Prof. H. T. H. Piaggio, 452
Fungal Origin : A New Antifungal Substance of (P. Delmotte and J. Delmotte-Plaquee), 344
Fungi and Bacteria : Physiology of the Host-Parasite Relationship in (Prof. W. Brown), 22
Fungi, Trees : Wild Flowers, Grasses, Ferns, (H. Trevor Jones), *review* by T. H. H., 143
*Fusarium* Contamination of Grain (W. L. Gordon), 375
*Fusarium vasinfectum* : Rooting of Cut Shoots of Cotton in Culture Filtrate of (R. Kalyanasundaram and K. Lakshminarayanan), 1120

GALACTOSE in *Saccharomyces cerevisiae* : Relationship between the Oxidative and Fermentative Phases during Adaptation to (Dr. A. Leonard Sheffner), 1073
Gall Stones : Formation of—Physical Properties of Bile Salts (A. J. H. Rains and N. Crawford), 829
Galvanized Iron : Effect of, on some Tree Seedlings (J. Hawkins and D. I. Cameron), 977
Games : Theory of (Dr. S. Vajda), 779
γ-Radiation : Reduction of Ferric Ion in Aqueous Solution by (C. B. Amphlett), 690
Gannet in New Zealand (C. A. Fleming and K. A. Wodzicki), 504
Garden Flora of Hardy Plants in France, *review* by Sir Edward Salisbury, 493
Garter Snakes : Seasonal Variation in the Reproductive System of (Wade Fox), 957
Gas : Natural, in Britain, 1052
  Natural, and Natural Gasoline (Prof. R. L. Huntington), *review*, 278
Gaseous Carbon Dioxide : Exchange of Carbon-13 Dioxide between Calcite Crystals and (R. A. W. Haul, L. H. Stein and J. W. L. de Villiers), 619
Gases of High Dielectric Strength : Negative-Ion Formation in (Dr. J. W. Warren, J. Marriott and Dr. J. D. Craggs), 514
Gasoline (Natural) : Natural Gas and (Prof. R. L. Huntington), *review*, 278
Gegenschein Studies in the Soviet Union : Recent, 555
Geiger-Muller Counters : Bibliography of (J. E. Walker), 677
Gene for Photoperiod Sensitivity in Rice linked with Apiculus Colour (Dr. M. F. Chandraratna), 1162
Gene Heterozygotes : Identification of Recessive, by means of Paper-Partition Chromatography (Prof. A. A. Buzzati-Traverso), 575
Genesis and Geology, a Study in the Relations of Scientific Thought, Natural Theology and Social Opinion in Great Britain, 1790–1850 (Charles Coulston Gillispie), *review* by V. A. Eyles, 714
Genetic Analysis of Intact Incomplete Asci of Yeast (E. A. Bevan), 576
Genetic Interaction between Influenza Viruses (Sir Macfarlane Burnet, K. B. Fraser and Patricia E. Lind), 163
Genetic Phenomenon in the House Mouse : Affinity, a New—Evidence from Distant Crosses (Donald Michie), 26 ; Evidence from within Laboratory Stocks (Mrs. Margaret E. Wallace), 27
Genetic and Morphological Evidence for Subspecific Differences between Naples and Plymouth Populations of *Ophryotrocha puerilis* (Dr. Guido Bacci and Dr. Marcello La Greca), 1115
Genetical Implications of the Structure of Deoxyribonucleic Acid (J. D. Watson and F. H. C. Crick), 964
Genetics : General (Adrian M. Srb and Ray D. Owen), *review* by Dr. G. Pontecorvo, 1039
  Microbial, at the University of Glasgow, 66
Genetics (Bacterial) : Terminology in (Prof. Boris Ephrussi, Dr. Urs Leopold, Dr. J. D. Watson and Prof. J. J. Weigle), 701
Genius : The Infirmities of (Dr. W. R. Bett), *review* by Dr. E. J. Dingwall, 586
  Psychopathology of, *review* by Dr. E. J. Dingwall, 586
Geography at Glasgow, 1094
Geography at Leeds, 1002
Geography at Oxford, 726
Geography and Food Resources (Association of Agriculture Course on), 777
Geological Survey of Great Britain (Sir Edward Bailey), *review* by Sir Arthur Trueman, 96
Geology : Genesis and, a Study in the Relations of Scientific Thought, Natural Theology and Social Opinion in Great Britain, 1790–1850 (Charles Coulston Gillispie), *review* by V. A. Eyles, 714
Geology in Great Britain : History of, *review* by Sir Arthur Trueman, 96
Geology and Prehistory of Uganda : The Pleistocene, Part 2, Prehistory (Dr. C. van Riet Lowe), *review* by M. C. Burkitt, 4
Geometrical Optical Aberrations : Newton's Work on (Prof. A. C. S. van Heel), 305
Geo-Morphology of $F_2$-Region Ionospheric Storms (Dr. D. F. Martyn), 14
Geophysical Prospecting (Dr. D. T. Germain-Jones), 202
*Geophysical Prospecting* : To be published by the European Association of Exploration Geophysicists, 202
Geophysical and Meteorological Changes in the Period January–April 1949 (Dr. W. J. G. Beynon and G. M. Brown), 967 ; (R. P. Waldo Lewis and D. H. McIntosh), 969
Geophysics : Research Studentship in (Royal Dutch-Shell Group), 729
Geophysics at the Carnegie Institution of Washington, 594
German Medical and Scientific Periodicals : Cost of (Springer Verlag), 403 ; (Dr. Wilfrid Bonser and Margaret P. Russell), 403
German Meteorological Service of the U.S. Zone, 331
Gerontological Research Fellowship (Nuffield Foundation), 462
'Giant' Fibres in Dragonfly Nymphs (Dr. G. M. Hughes), 87
Gill Memorial of the Royal Geographical Society awarded to B. H. Farmer, 636
Glass : Effects of Different Water-regimes on the Growth of Tomatoes under (J. P. Hudson and P. J. Salter), 480
Glass in Chemical Industry, 1052
Globulin Fractions of Anti-D Sera separated by Paper Electrophoresis : Serological Activity of (Branislav D. Janković and Herman W. Knjoen), 982
*Gloriosa superba*, Linn : Doubling of Chromosomes induced by Gloriosine isolated from (L. S. S. Kumar), 791
Gloriosine isolated from *Gloriosa superba*, Linn. : Doubling of Chromosomes induced by (L. S. S. Kumar), 791
Gloss of Papers (V. G. W. Harrison and S. R. C. Poulter), 651
D-Glucosamine : Inhibition of Tumour Growth by (Prof. J. H. Quastel and Dr. A. Cantero), 252
Glucose : Insulin and the Permeability of Cell Membranes to (E. J. Ross), 125
Glucose from the Intestine : Active Absorption of (S. Hestrin-Lerner and Prof. B. Shapiro), 745
Glucose, Arabinose and Xylose in Jute : Association of (Dr. D. B. Das, M. K. Mitra and J. F. Wareham), 613
Glucose and Fructose : Radioactive Starch, from Tobacco Leaves (H. K. Porter and R. V. Martin), 505
Glucose Utilization in the Isolated Rat Diaphragm : Effect of Acetoacetate on Glycogen Synthesis and (A. Chain and E. Wertheimer), 44

Glucose-Level (Blood): Influence of the, on the Secretion of Adrenalin and Noradrenalin from the Suprarenal Medulla (Hans Dunér), 481
Glycosides: A New Procedure for Correlating the Structure of (M. Abdel Akher, J. E. Cadotte, R. Montgomery, Prof. F. Smith, J. W. Van Cleve and Bertha A. Lewis), 474
N-Glucosides (Aromatic): Transglucosylation of (Prof. R. Bognár and P. Nánási), 475
Glutamic Acid: Transfer of Labelled Nitrogen from, to Pine Seedlings through the Mycelium of *Boletus variegatus* (Sw.) Fr. (Prof. Elias Melin and Harald Nilsson), 134
L-Glutamic Acid Analogues: Effect of, on the Enzymatic Formation of Hydroxamic Acid (N. Lichtenstein, Helen E. Ross and Prof. Philip P. Cohen), 45
Glutathione and Mercaptoethylamine: Therapeutic Action of, against a Lethal Dose of X-Rays (Prof. J. H. Maisin, G. Lambert, M. Mandart and H. Maisin), 971
Glycerol in Fermentation Solutions: Determination of—a Rapid Chromatographic Procedure (A. F. Williams), 655
Glycogen Synthesis and Glucose Utilization in the Isolated Rat Diaphragm: Effect of Acetoacetate on (A. Chari and E. Wertheimer), 44
Gnade: Leibniz und das Reich der (Kurt Hildebrandt), *review* by F. I. G. Rawlins, 992
God: Modern Cosmology and the Christian Idea of (E. A. Milne), *review* by Sir Harold Spencer Jones, 584
Gods, Graves and Scholars, the Story of Archæology (C. W. Ceram), translated from the German by E. B. Garside, *review* by M. C. Burkitt, 765
Gold Medal of the Royal Astronomical Society awarded to Prof. S. Chandrasekhar, 108
Goodacre (Walter) Medal and Gift of the British Astronomical Association presented to Frank Maurice Holborn, 244
*Gordoderina vitelliloba* (Olsson): Life-history of (E. Lees), 485
Gotland Island: Rabbit Problem in (G. Notini and S. Forsellus), 374
Government: Science and (Dr. L. A. DuBridge), 1059
Government (Parliamentary): Problems of, in Colonies (Hansard Society), 1130
Government in a Democracy: Mechanism of, 183
Government Assistance to Universities in Great Britain (Memoranda submitted to the Commission on Financing Higher Education by Harold W. Dodds, Louis M. Hacker and Lindsay Rogers), 273
Government Information and the Research Worker (edited by Ronald Staveley), *review* by R. B., 188
Government Scientific Establishments: Research Fellowships at, 200
Government Scientific Research in Great Britain, 709
Government Services: Science in, 1146
Grafting: Effect of, on Nodulation of *Trifolium ambiguum* (P. W. Hely, Ch. Bonnier and P. Manil), 884
Gram: *Fusarium* Contamination of (W. L. Gordon), 375
Gram-negative Bacterial Rods: Contamination of *Azotobacter chroococcum* by (Ernest A. Grey), 1163
Grants (Quinquennial): The Principle of, 317
Grants, Scholarships and Fellowships for research on Diseases of the Blood (Lady Tata Memorial Fund), 246
Graphite (Synthetic): Closed Pores in (Miss E. M. Dresel and Dr. L. E. J. Roberts), 170
Graphitic Acid from Aromatic Compounds by Peroxide Treatment (G. A. Bottomley and J. G. Blackman), 620
Grass (Fresh): Acetic Acid in (Dr. A. J. G. Barnett and R. E. B. Duncan), 478
Grasses, Ferns, Fungi, Trees, Wild Flowers, (H. Trevor Jones), *review* by T. H. H., 143
Graves and Scholars: Gods, the Story of Archæology (C. W. Ceram), translated from the German by E. B. Garside, *review* by M. C. Burkitt, 765
Great Britain: Adult Education in, 759
  Autonomy of Universities in, 273
  Careers in Agricultural Research in, 330
  The Civil Service in, *review* by R. Brightman, 362
  Geological Survey of (Sir Edward Bailey), *review* by Sir Arthur Trueman, 96
  Government Assistance to Universities in (Memoranda submitted to the Commission on Financing Higher Education by Harold W. Dodds, Louis M. Hacker and Lindsay Rogers), 273
  Government Scientific Research in, 709
  History of Geology in, *review* by Sir Arthur Trueman, 96
  Library Co-operation in; Report of the National Central Library and the Regional Library Bureaux (Robert F. Vollans), 1144
  Marine Biology Research in (Dr. N. B. Eales), 828
  National Parks in, 558
  Petroleum Chemicals Industry in, 679
  Recruitment of Scientists and Technologists in, 866
  Sample Tables for the 1951 Census of (E. Grebenik), 816
  Survey of Food Consumption and Expenditure in (Miss M. W. Grant), 426
  Technological Education in, 109
  See *also under* Britain
Great Britain and Ireland: Check-List of the Birds of (British Ornithologists' Union), 781
Green Thoughts (Sir Stephen Tallents), *review*, 188
Greenwich Meridian, 1140
Gregariousness in Barnacles in relation to the Fouling of Ships and to Anti-Fouling Research (Dr. E. W. Knight-Jones and Dr. D. J. Crisp), 1109
Greystone Hospital: Psychosurgical Studies at the, *review* by Dr. H. J. Eysenck, 231
Grinding: Electrical Conductivity of certain Crystalline Materials after (J. S. Dryden and Dr. R. J. Meakins), 307
Group Prejudices in India (edited by Sir Manilal B. Nanavati and C. N. Vakil), *review* by Prof. J. H. Hutton, 810
Growth: Effect of Continued Iron Administration on (Dr. J. A. Nissim), 1157
  Manganese Requirements of Tomato Plants at Different Phases of (M. Bakr Ahmed and Prof. E. S. Twyman), 438
Growth (Normal): Some Chemical Aspects of (Prof. F. Bergel), 905
Growth of Influenza Virus in the Chick Chorion (Alick Isaacs and Dr. Forrest Fulton), 90
Growth of a Parasitic Protozoan: A Method for the Bulk (Dr. Joseph G. Feinberg), 1165
Growth of Tomatoes under Glass: Effects of Different Water-regimes on the (J. P. Hudson and P. J. Salter), 480
Growth and Axon Formation in the Midbrain of the Chicken Embryo (Dr. R. J. O'Connor), 131
Growth and Optical Properties of Stearic Acid Crystals (P. M. Reynolds and Ajit Ram Verma), 486
Growth and Security: Foundations for (Resources for Freedom, a Report to the President by the President's Materials Policy Commission, Vol. I), 1
Growth-Factors for *Trichomonas foetus*: Serum as a Source of (J. K. Clausen), 1067
Growth-Inhibitor for Streptomycin-resistant Mutants in Dense Suspensions of *Brucella abortus* (Strain 19), (Dr. A. L. Olitzki), 132
Growth-Structure in Metal Single Crystals: A Special Kind of (Dr. P. Blaha), 650
Growth-Substances in Plant Extracts: Chromatography of the (Prof. T. A. Bennet-Clark and N. P. Kefford), 645
Gunning Victoria Jubilee Prize for 1948–52 of the Royal Society of Edinburgh awarded to Prof. A. C. Aitken, 867
Guthrie Lecture of the Physical Society (Prof. M. Born), 290

HABITAT, Vegetation and Man (Prof. W. H. Pearsall), 367
*Habrobracon*: Effects of Methyl *bis* (beta-Chloroethyl) Amine Hydrochloride on Haploid and Diploid Embryos of (A. M. Clark and W. C. Besser, Jun.), 178
Hadfield (Sir Robert) Medal for 1953 of the Iron and Steel Institute awarded to W. E. Bardgett, 506
Hæmagglutination (Influenza Virus): Separation of an Inhibitor of, from Human Sputum (G. Curtain, Dr. B. P. Marmion and J. Pye), 33
Hæmoglobin and Biliverdin in Parasitic Cirripede Crustacea (Prof. H. Munro Fox), 162
Hæmoglobin Metabolism (Section of Pathology of the Royal Society of Medicine Symposium on), 464
Hæmoglobin Molecule: Position of Hæms in the (Prof. D. Keilin), 922
Hæmoglobin Synthesis by *Daphnia*: Influence of Temperature and Iron on (Prof. H. Munro Fox, Elizabeth A. Phear and Barbara M. Gilchrist), 347
Hæmolytic Action of Diacetyldeoxycholate: Adsorption and (Dr. R. Cross and R. Ruyssen), 846
*Hæmonchus contortus* in Sheep fed on White Clover (*Trifolium repens*) High in Lotaustralin: Inhibition of Populations of (J. H. Tetley), 311
Hæms in the Hæmoglobin Molecule: Position of (Prof. D. Keilin), 922
*Halidrys siliquosa* Lyngb.: Incidence of Meiosis in the Life-cycle of (Dr. Eveline Elliot and Betty Moss), 357
Hall (Wilfred) Telescope, 154
Halogens: Laws of Addition and Substitution in Atomic Reactions of (Jean Adam, P. A. Gosselain and Prof. P. Goldfinger), 704
Hamster (Golden): Production of 'Three-Group Metaphases' in the Bone-Marrow of the (Dr. R. Parmentier), 1029
Haploid and Diploid Embryos of *Habrobracon*: Effects of Methyl *bis* (beta-Chloroethyl) Amine Hydrochloride on (A. M. Clark and W. C. Belser, Jun.), 178
Hardening of Kaolin on Rehydration (R. D. Hill), 567
Harmonics (Even and Half-odd): Piezo-electric Oscillations of Quartz Plates at (Dr. S. Parthasarathy, M. Pancholy and A. F. Chhapgar), 216
Harmony of Proportions, *review* by F. I. G. Rawlins, 1037
Harvest Untaken: Man's Loss of Crops from Pest, Weed and Disease (George Ordish), *review* by Dr. L. Thomas, 665
Harwell, the British Atomic Energy Research Establishment 1946–1951, 205
Harwell: Atomic Energy Research at, 205
Hatching from Cysts of the Potato Root Eelworm: Seasonal Fluctuations in the Degree of (David W. Fenwick and Elizabeth Reid), 47
Hatching Responses in Root Eelworms (*Heterodera* spp.), (F. G. W. Jones and R. D. Winslow), 478
Hauraki Gulf, New Zealand: Seasonal Variation in the Plankton and Salinity of the (A. S. Fuller), 525
Hawaii: Old, *review* by Dr. G. H. S. Bushnell, 764
Hawaiian Antiquities (Moolelo Hawaii), (David Malo), translated from the Hawaiian by Dr. Nathaniel B. Emerson, second edition, *review* by Dr. G. H. S. Bushnell, 764
Head of Crustaceans, Insects and Vertebrates: Neurosecretory Pathways in the (Prof. Bertil Hanström), 72
Health of the School Child, 996
Health Education (Cyril Bibby), *review* by Miss P. M. Taylor, 186
Health Education in Rumania (Dr. S. Leff), 728
Heat Exchanges of a Muscle Model (Dr. M. G. M. Pryor), 213
Heat Inactivation of Strawberry Viruses (Dr. A. F. Posnette), 312
Heat Tolerance of Cattle and Buffaloes: Some Factors affecting (A. A. Asker, M. T. Ragab and M. A. Ghany), 1074
Heating with Alkali: Artefacts produced from 3-Iodo-Tyrosine and 3:5-Di-iodo-Tyrosine by (P. G. Stanley), 933
Heavy-Particle Accelerator (J. W. Gallop), 306
Height: Shadow Microscopy for Measurement of (Prof. S. Tolansky), 564
Heineman (Dannie) Prize of the Heineman Foundation for Research, Educational, Charitable and Scientific Purposes awarded to Prof. Otto Neugebauer, 594
Heineman (Dannie) Prize of the Heineman Foundation for Research, Educational, Charitable and Scientific Purposes: Offer of a, 1005
Heinz Bodies: Nature of the (G. Rozsa and S. S. Spicer), 84
Hepatic Artery and Hepatic Vein within the Mammalian Liver: Anatomical and Physiological Evidence of Anastomoses of the (Dr. W. H. Horner Andrews and Prof. B. G. Maegraith), 222
Hepatomas (Malignant): Rapid Production of, by Simultaneous Administration of Tannic Acid and 2-Acetylaminofluorene (Dr. Martha Mosonyi and Dr. Béla Korpássy), 791
Herbage: Excess of Molybdenum in, as a Possible Contributory Factor in Equine Osteodystrophia (Dr. T. Walsh and Dr. L. B. O'Moore), 1166
Herbage on Acid Soils: High Molybdenum Levels in (Dr. T. Walsh, M. Neenan and Dr. L. B. O'Moore), 1120
Herbarium of Indian Plants at the Liverpool Public Museums (H. Stansfield), 1096
Heredity: Understanding (Richard B. Goldschmidt), *review* by Dr. G. Pontecorvo, 496

*Heterodera* spp. : Hatching Responses in Root Eelworms (F. G. W. Jones and R. D. Winslow), 478
Heterozygotes Identification of Recessive Gene, by means of Paper-Partition Chromatography (Prof. A. A. Buzzati-Traverso), 575
Hexose Sugars : Radioactive Starch and, 505
Hexose Sugars with Anthrone : Interference of Pentose in the Estimation of (R. Johanson), 176
Hides and Skins : Drying of (J. R. Furlong), 294
High-Frequency Phenomena and Electrical Direct Heating : Some Researches on, 957
High-Resolution Aerial for Radio Astronomy (W. N. Christiansen), 831
Hinchley Medal of the British Association of Chemists awarded to Dr. Herbert Levinstein, 333
Histidine Hydrochloride Monohydrate : Crystal Structure of (Jerry Donohue), 258
Histochemical Demonstration of Amine Oxidase in Liver (C. M. Francis), 701
Histochemical Detection with Ditetrazolium Chloride of some Enzymatic Activities in Isolated Mitochondria (Dr. Mario Umberto Dianzani), 125
Histochemical Observations on Periodic Acid–Amino-Acid Mechanisms Some (Dr. John F. Lhotka), 1123
Histochemistry of Succinic Dehydrogenase (Dr. H. A. Malaty and Dr. G. H. Bourne), 295
Historic Books on Machines : Exhibition of (Science Museum, London), 820
*Holcus mollis* : Chromosome Numbers in (A. R. Beddows and Keith Jones), 938
Holweck Medal and Prize for 1953 awarded to J. A. Ratcliffe, 678
Home Civil Service Fellowships (Commonwealth Fund), 596
Hominoid Material Fossil, collected by the British-Kenya Miocene Expedition (Prof. W. E. Le Gros Clark), 18
Hommes fossiles . Les (Prof. Marcellin Boule et Prof. Henri V. Vallois), quatrième édition, *review* by Prof. W. E. Le Gros Clark, 361
Homogenates (Pigeon Liver) . Formation of Adenine Nucleotides from Adenine by (Eugene Goldwasser), 126
Homografts (Skin) . Intolerance of Dizygotic Twin Lambs to (G. H. Lampkin), 975
Homology of the Layers of the Epicuticle of Insects (Prof. R. Dennell and Dr. S. R. A. Malek), 298
Homozygosis, and the Search for New Blood Groups 'Private' Blood Factors, (Dr. Bruce Chown and Marion Lewis), 700
Honours : Coronation, 1002
Honours List : New Year, 64
Hop Mosaic Transmission of, by *Phorodon humuli* (Schrank), (J. Paine and J. T. Legg), 263
Hop Stems Resistance of, to Invasion by *Verticillium albo-atrum* (W. G. Keyworth), 656
Hopkins Prize of the Cambridge Philosophical Society awarded to Sir John Lennard-Jones, 777
Hormonal Nature of Extracts of Parathyroid Gland stimulating Phosphate Excretion (Beryl M. A. Davies and A. H. Gordon), 1122
Hormone B (Melanophore Expanding) Relation of Adrenocorticotrophin (ACTH) to the, of the Pituitary (Prof. H. Waring and B. Ketterer), 862
Hormones (Ovarian) : Influence of, on Uterine Infection (L. E. Rowson, G. E. Lamming and R. M. Fry), 749
Horrebow Star-Pairs for the Determination of Northern Latitudes Catalogue of, 505
Host-Parasite Relationship in Fungi and Bacteria : Physiology of the (Prof. W. Brown), 22
Hotu Cave, Iran : Archæological Excavations in the (C. S. Coon), 821 ; (Louis B. Dupree), 821 , (J. L. Angel), 821
House Mouse Affinity, a New Genetic Phenomenon in the—Evidence from Distant Crosses (Donald Michie), 26 ; Evidence from within Laboratory Stocks (Mrs. Margaret E. Wallace), 27
  A Dominant Sex-linked Mutation in the (E. D. Garber), 332 ; (Dr. D. S. Falconer), 638
Houseflies and Body Lice : Forms of Insecticide-Resistance in (Dr. J. R. Busvine), 118
Housing in the Tropics (United Nations, Department of Social Affairs, Town and Country Planning Bulletin No. 6), 461
Howe (Harrison) Lecture for 1953 of the Rochester Section of the American Chemical Society (Prof. Herbert C. Brown), 1095
Human Brain Vesalius on the (Charles Singer), *review* by Prof. F. J. Cole, 899
Human Factors in Industry, 684
Human Foetal Adrenals and Aortic Bodies . Determination of Adrenalin and Noradrenalin in the (Kalevi Nieminева and Aimo Pekkarinen), 436
Human Performance (Ergonomics Research Society Symposium on), 290, 960
Human Relations in Industry, 137 ; (T. H. Hawkins), 338
Human Relations in Industry Conference : Report of the (Ministry of Labour and National Service), 623
Human Sputum : Separation of an Inhibitor of Influenza Virus Hæmagglutination from (C. Curtain, Dr. B. P. Marmion and J. Pye), 33
Humidity of the Upper Troposphere and Lower Stratosphere over Southern England (J. K. Bannon, R. Frith and H. C. Shellard), 381
Hyaluronidase : Effect of, on the Mortality from Experimental Burns (Edith Rosenberg, C. R. McComb, A. W. Farmer and W. R. Franks), 431
  Non-Effect of, on the Spread of Œstrone (Mary E. Bromhead (Mrs. Webster) and Prof. Paul G. 'Espinasse), 46
Hyaluronidase as an Adjuvant to Methylene Blue in staining of Nerve Fibres (Ian A. McGregor), 1070
Hyaluronidase and Salicylates (Dr. T. D. Day), 268
Hydration of Metal Cations (Dr. E. Glueckauf and G. P. Kitt), 1010
Hydrobiology and Inland Fisheries of Africa (Scientific Council for Africa South of the Sahara Symposium on), 291
Hydrochloride Monohydrate (Histidine) . Crystal Structure of (Jerry Donohue), 258
Hydro-electricity in North Wales, 332
Hydrogen Bonds in Boric Acid . Electron Diffraction Study of the (Dr. J. M. Cowley), 440
Hydrogen Chloride in Concentrated Solutions : Activity Data and the Association of (A. M. Potter), 519
Hydrogen Flames containing Alkali Metals : Resonance Radiation from (C. G. James and Dr. T. M. Sugden), 428
Hydrogen Peroxide : Degradation of Methionine by (Yoshihiko Matsuo), 1021
Hydrolysates (Unneutralized) Use of, in Paper Chromatography of Sugars (Blanche D. E. Gaillard), 1160
Hydrolysis of Adenosine Triphosphate catalysed by Lobster Muscle . Mechanism of (Edith Clarke and D. E. Koshland, jun.), 1023
Hydrolysis of Anhydrides by Esterases (Prof. Felix Bergmann, Menachem Wurzel and Arela Shimoni), 744
Hydroponics, the Bengal System (J. Sholto Douglas), *review* by Prof. R. H. Stoughton, 364
Hydroxamic Acid : Effect of L-Glutamic Acid Analogues on the Enzymatic Formation of (N. Lichtenstein, Helen E. Ross and Prof. Philip P. Cohen), 45
Hydroxylamine in Lake Waters as an Intermediate in Bacterial Reduction of Nitrate : Occurrence of (Motoharu Tanaka), 1160
Hygiene (Tropical) Course in, for Laymen (Ross Institute of Tropical Hygiene), 333
Hymenoptera (Tenthredinidæ) : Reversal of Phototaxis in Prepupæ of, caused by Amyl Acetate Vapour emanating from Marking Paint (Dr. F. L. Waterhouse), 438
Hyoscine in *Duboisia myoporoides* R. Br. : Occurrence of Nicotine together with (K. Loftus Hills, W. Bottomley and P. L. Mortimer), 435
Hypothalamus Functional Relations of the Adenohypophysis and (A. P. D. Thomson and Prof. S. Zuckerman), 970
Hyrax and Elephant : Serological Relationships of (Bernard Weitz), 261

ICE Thickness in Dronning Maud Land, Antarctica : Measurements of (G. de Q. Robin), 55
Identification of the Constituents of Coal Dust : Microscopical (Dr. R. G. H. B. Boddy), 928
Identification of 4-Methyl-D-glucuronic Acid in *Eucalyptus regnans* Wood (C. M. Stewart and D. H. Foster), 792
Identification of Radiosensitive Volume with Nucleic Acid Volume (H. T. Epstein), 394
Identification of Recessive Gene Heterozygotes by means of Paper-Partition Chromatography (Prof. A. A. Buzzati-Traverso), 575
Imitation in Childhood . Play, Dreams and (Prof. Jean Piaget), translated by C. Gattegno and F. M. Hodgson, *review* by Prof. John Cohen, 450
Immobilization Test (Treponemal) Elimination of Inconclusive Results in the (Hans Aage Nielsen), 1030
Inactivation of Polyploid *Saccharomyces* : X-Ray (W. H. Lucke and A. Sarachek), 1014
Inactivation of Strawberry Viruses : Heat (Dr. A. F. Posnette), 312
Incas . Lost City of the, the Story of Machu Picchu and its Builders (Hiram Bingham), *review*, 453
Inconclusive Results in the Treponemal Immobilization Test : Elimination of (Hans Aage Nielsen), 1030
India . Caste and Class in (Prof. G. S. Ghurye), *review* by Prof. J. H. Hutton, 810
  Education in, 733
  Food and Population and Development of Food Industries in, *review* by Sir John Russell, 1038
  Group Prejudices in (edited by Sir Manilal B. Nanavati and C. N. Vakil), *review* by Prof. J. H. Hutton, 810
  Occurrence of *Verticillium* in Potato Tubers in (Prof. K. S. Bhargava and Hari Kishore), 800
India's Food Problems, *review* by Sir John Russell, 1038
Indian Caste of Peru, 1795–1940 (George Kubler), 686
Indian Ocean (Western) Catches of *Coryphaena hippurus* (L.) in the (F. Williams), 703
Indian Plants at the Liverpool Public Museums Herbarium of (H. Stansfield), 1096
Indian Timbers Seasoning Behaviour of (M. A. Rehman), 504
Indian Views on Plural Society, *review* by Prof. J. H. Hutton, 810
Indicator Yellow Rhodopsin and (Dr. F. D. Collins), 469
3-Indolylacetonitrile, an Important Plant Hormone (J. A. Bentley, S. Housley and A. S. Bickel), 505
Indoors . Differences in the Vitamin $B_{12}$ Content of Cow's Milk during the Last Month; and the First Week at Pasture (E. E. van Koetsveld), 483
Induction of Male Cones in *Pinus sylvestris* . Experimental (Dr. P. F. Wareing), 47
Industrial Application of Aerodynamic Techniques (National Physical Laboratory, Notes on Applied Science No. 2), 1097
Industrial Chemical Equipment in the United States (Prof. H. E. Watson), 204
Industrial Chemistry . Twenty-sixth International Congress of (Société de Chimie Industrielle), 776
Industrial Firms Technical Resources of, 676
Industrial Operatives Book Service for (National Book League), 420
Industrial Problem From Examination Question to (J. F. Hinsley), 779
Industries (Nationalized) : Research in, 447
Industry . Antibiotics, their Production and Uses in (Society for Applied Bacteriology Symposium on), 914
  Human Factors in, 684
  Human Relations in, 137 ; (T. H. Hawkins), 338
  Human Relations in (Report of the Conference on), (Ministry of Labour and National Service), 623
  The Place of University Graduates in, 870
  Radioisotope Techniques in, 1007
  Science in (Sir Ben Lockspeiser), 65
  Scientific Instruments in Research and, 1081
  Scientific Instruments for Research and—Physical Society's Exhibition, 1953 (Dr. A. B. Wood), 812
  Secondary Technical Schools and (H. B. Brown), 636
  Soft Magnetic Materials used in (A. E. DeBarr), *review* by S. Weintroub, 1132
  Universities and , Report of the Conference on (Federation of British Industries and the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom, October 1952), 870
Industry (Nationalized) . Problems of (edited by Prof. William A. Robson), 448

- Industry and the Universities : Report of the Conference on (Federation of British Industries (North Midland Regional Council) and the University of Nottingham, September 1952), 962
- Infectivity of Aphids after Several Hours on Tobacco Infected with Potato Virus Y (Dr. R. H. E. Bradley), 755
- Infertility and Sterility : Prize for a contribution to the subject of (American Society for the Study of Sterility), 156
- Infiltration of Liquids into Leaves : Apparatus for (Arwyn Charles), 1166
- Infinity (Mathematical Association Discussion on), 779
- Infirmities of Genius (Dr. W. R. Bett), *review* by Dr. E. J. Dingwall, 586
- Inflorescence Apex (Angiosperm) Structure of the (Dr. John G. Vaughan and F. R. Jones), 751
- Influenza Virus Electron Microscope Studies of the Structure of the (L. Hoyle, Dr. R. Reed and Prof. W. T. Astbury), 256
- Influenza Virus in the Chick Chorion : Growth of (Alick Isaacs and Dr. Forrest Fulton), 90
- Influenza Virus Haemagglutination from Human Sputum : Separation of an Inhibitor of (C. Curtain, Dr. B. P. Marmion and J. Pye), 33
- Influenza Viruses : Genetic Interaction between (Sir Macfarlane Burnet, K. B. Fraser and Patricia E. Lind), 163
- Information (Technical) : Presentation of (J. W. Godfrey), 728
- Information and the Research Worker : Government (edited by Ronald Staveley), *review* by R. B., 188
- Infra-Red Radiation . New Spectrophotometer for Visible and Near (Unicam Instruments (Cambridge), Ltd.), 200
- Infra-Red Spectra of Coals and Coal Products (C. G. Cannon), 308
- Inheritance (Quantitative) : Analysis of Environmental Variability in (E. C. R. Reeve and F. W. Robertson), 874
- Inheritance of Minor Colour Vision Variations (Dr. R. W. Pickford), 1167
- Inherited Character in the Rat : Effect of Nitrogen Mustard on an (P. Armitage), 1117
- Inhibition (Primary) : Strychnine as a Depressant of (K. Bradley and Prof. J C. Eccles), 1061
- Inhibition of *E. coli* Strains by Amino-Acids (D. Rowley), 80
- Inhibition of Populations of *Haemonchus contortus* in Sheep fed on White Clover (*Trifolium repens*) High in Lotaustralin (J. H. Tetley), 311
- Inhibition by Surface-active Agents . Curves of Succinoxidase (Dr. Sumner M. Kalman), 568
- Inhibition of Tumour Growth by D-Glucosamine (Prof. J. H. Quastel and Dr. A. Cantero), 252
- Inhibition and Activation of Lysozyme (Dr E Kaiser), 607
- Inhibition Effects in Back-Mutation Tests with Mutants of *Neurospora* (C. M. Stevens and A. Mylroie), 179
- Inhibitor of Influenza Virus Haemagglutination from Human Sputum : Separation of an (C Curtain, Dr. B. P. Marmion and J. Pye), 33
- Inhibitory Effect of Malonate on the Respiration of Brain Tissue, with special reference to the Potassium Effect (Y. Kimura and T. Niwa), 881
- Insect Behaviour : A Simple 'Response Balance' for studying (Dr. H. Hurst), 1120
- Insect Cuticle : Permeability of, to Aqueous Stains and Vulnerability to Insecticides (S. Mukerji and S. N. Chatterjee), 119
- Insecticide Field Trials : Use of Repellents to simplify (K. A McKinlay), 658
- Insecticide 'Schradan' : Contamination of Nectar with the Systemic (Dr. G. D. Glynne Jones and Dr. W. D. E. Thomas), 263
- Insecticide-Resistance in Houseflies and Body Lice : Forms of (Dr. J. R. Busvine), 118
- Insecticides : Permeability of Insect Cuticle to Aqueous Stains and Vulnerability to (S. Mukerji and S. N Chatterjee), 119
  - Physical Factors in relation to Biological Activity of (Crop Protection Panel of the Agriculture Group of the Society of Chemical Industry Discussion on), 869
- Insecticides and Colonial Agricultural Development (Colston Research Society Symposium on), 824
- Insects Flight-tone and Wing-stroke Frequency of (Dr. C. F. A. Pantin), 225
  - Homology of the Layers of the Epicuticle of (Prof. R. Dennell and Dr. S. R. A. Malek), 298
  - Leaf-Mining, *review* by V. W. Fowler, 763
- Insects of France : Orthopteroid, *review* by David R. Ragge, 626
- Insects of Micronesia, 638
- Insects and Spiders (H. Trevor Jones), *review* by T. H. H., 143
- Insects and Vertebrates : Neurosecretory Pathways in the Head of Crustaceans, (Prof. Bertil Hanström), 72
- Instrument Industries Exhibition : Second British, 822
- Instrumentation of Nuclear Reactors (Institution of Electrical Engineers Symposium on), 411
- Insulators : Effect of Temperature on the Conductivity Induced in, by X-Rays (J. F Fowler and Dr. F. T. Farmer), 1020
- Insulin : Action of, on the Frog (*Rana temporaria*), (C. L Smith), 311
  - Reversible Dissociation of (Eugène Fredericq), 570
- Insulin and the Permeability of Cell Membranes to Glucose (E J. Ross), 125
- Integral : The Lebesgue (J. C. Burkill), *review* by Prof. H. T. H Piaggio, 452
- Integration Modern Theories of, *review* by Prof. H. T. H. Piaggio, 452
- Integration of Scientific Thought, 244
- Integrazione : Lezioni sulla teoria moderna dell' (Prof. Mauro Picone e Tullio Viola), *review* by Prof. H. T. H. Piaggio, 452
- Integument of *Asterias rubens* : Protoporphyrin in the (G. Y. Kennedy and Dr. H. G. Vevers), 81
- Intensity Distribution of the Second Positive Nitrogen Bands excited in a Nitrogen Ozonizer : Effect of Irradiation on the (Dr. S. K. Asundi and N. Appalanarasimham), 86
- Inter-Relationships of Endocrine Systems and their Psychological Effects : Chemistry and (Society for Visiting Scientists Discussion on), 509
- Interaction of Chlorine Dioxide with Flour—Certain Chemical Aspects (Dr. T. Moran, Dr. J. Pace and E. E. McDermott), 103
- Interaction of Manganous Ions with Enolase (Dr. Bo G. Malmström), 392
- Interchange Reaction : A Disulphide (Dr. F. Sanger), 1025
- Interferometer Microscope for the Accurate Measurement of Optical Thickness (J. Dyson), 743
- Interferometers : Modern (C. Candler), *review* by K. J. Habell, 321
  - Reference Book of, *review* by K. J. Habell, 321
- Interglacial Deposit at Ipswich : A Riss-Wurm (Harold E. P. Spencer), 578
- Interior of the Earth Temperature of the (Prof. J. A. Jacobs), 835
- Intermolecular Force and Transport Coefficients (B. N. Srivastava and M. P. Madan), 441

- International Tables for X-Ray Crystallography, Vol. I, Symmetry Groups (edited by Norman F. M. Henry and Kathleen Lonsdale), *review* by Prof. P. P. Ewald, 944
- International Trade in Agricultural Machinery, 199
- Internationalen Pflanzengeographischen Exkursion durch Irland 1949 : Ergebnisse der 9—Die Pflanzenwelt Irlands (redigiert von Werner Lüdi), *review* by Prof. P. W. Richards, 1085
- Interplanetary Orbits (J. G. Porter), 374
- Intestinal Flora and Thiamine Synthesis brought about by Curd Feeding : Influence of Sulphaguanidine on the (S. Balakrishnan and Dr. R. Rajagopalan), 608
- Intestine : Active Absorption of Glucose from the (S. Hestrin-Lerner and Prof. B. Shapiro), 745
- Intolerance of Dizygotic Twin Lambs to Skin Homografts (G. H. Lampkin), 975
- Iodination of Keratin (H. R. Richards and Prof. J. B. Speakman), 751
- 3-Iodo-Tyrosine and 3 : 5-Di-iodo-Tyrosine Artefacts produced from, by Heating with Alkali (P. G. Stanley), 933
- Iodoethane : Microwave Spectrum and Structure of (Dr. A. H. Sharbaugh, G. A. Heath, L. F. Thomas and Dr. J. Sheridan), 87
- Ion Absorption by Roots : Mechanism of (Emanuel Epstein), 83
- Ion Chambers . A. C. Operation of (Dr. A. H. Ward), 837
- Ion-Exchange in Paper Chromatography (J. B. Schute), 839
- Ion-Exchange Columns of 'Amberlite IRA 400 (OH')' : Degradation of Sugars on (J. D. Phillips and Dr. A. Pollard), 41
- Ion-Exchange Resins : Separation of Neutral Proteins on (N. K. Boardman and Dr. S. M. Partridge), 208
  - Use of, in Paper Chromatography of Sugars (Dr. L. I. Woolf), 841
- Ion-Exchanging Surfaces in Radiological Decontamination (E. W. Jackson and Miss L. Garrard), 442
- Ionium Determination in Deep-Sea Sediments (Mlle. N. Isaac and Dr. E. Picciotto), 742
- Ionization : Methods of obtaining High Vacuum by—Construction of an 'Electronic Pump' (Dr. Helmut Schwarz), 600
- Ionization Phenomena in Discharges (Clarendon Laboratory, the Institute of Physics, the Physical Society and the British Electrical and Allied Industries Research Association Conference on), 463
- Ionizing Radiation : Effect of Lymphocytes on (Prof. R. J. V. Pulvertaft, C. W. Wilson and Howard Jayne), 1157
- Ionophoresis and Microbiological Assay : Differentiation of Vitamin $B_{12}$ Active Compounds by—Ionophoresis (Dr. E. S. Holdsworth), 148 ; Microbiological Tests (J. E. Ford), 149 ; Occurrence of the various Vitamin $B_{12}$ Active Compounds (J. E. Ford, Dr. E. S. Holdsworth, Dr. S. K. Kon and Dr. J. W. G. Porter), 150
- Ionosphere . Abnormalities in the, at High Latitudes (W. R. Piggott), 124
  - Travelling Disturbances in the—Diurnal Variation of Direction (G. H. Munro), 693
  - Wave Hypothesis of Moving Irregularities in the (C. O. Hines), 980
- Ionospheric Echoes at 150 kc./s. . Long-Delay (J. J. Gibbons, R. L. Schrag and Prof. A. H. Waynick), 444
- Ionospheric Storms ($F_2$-Region) : Geo-Morphology of (Dr. D. F. Martyn), 14
- Ions (Heavy) . Acceleration of, to High Energies (Dr. D. Walker and Dr. J. H. Fremlin), 189
- Ions (Manganous) . Interaction of, with Enolase (Dr. Bo G. Malmström), 392
- Ipswich : A Riss-Wurm Interglacial Deposit at (Harold E. P. Spencer), 578
- Iraq : Agricultural Census in (Dr. K. G. Fenelon), 821
- Ireland : Check-List of the Birds of Great Britain and (British Ornithologists' Union), 781
  - Flora and Vegetation of, *review* by Prof. P. W. Richards, 1085
- Irlands : Die Pflanzenwelt (Ergebnisse der 9 Internationalen Pflanzengeographischen Exkursion durch Irland 1949, redigiert von Werner Lüdi), *review* by Prof. P. W. Richards, 1085
- Iron : Influence of Temperature and, on Haemoglobin Synthesis by *Daphnia* (Prof. H. Munro Fox, Elizabeth A. Phear and Barbara M. Gilchrist), 347
- Iron (Galvanized) : Effect of, on some Tree Seedlings (J. Hawkins and D. I. Cameron), 977
- Bis-cyclopentadienyl Iron, a Molecular Sandwich (J. D. Dunitz and L. E. Orgel), 121
- Iron Administration : Effect of Continued, on Growth (Dr. J. A. Nissim), 1157
- Iron-binding Capacity in the South African Bantu : Serum Iron and (Th. Gerritsen and A. R. P. Walker), 699
- Irradiation : Effect of, on the Intensity Distribution of the Second Positive Nitrogen Bands excited in a Nitrogen Ozonizer (Dr. R. K. Asundi and N. Appalanarasimham), 86
- Irradiation (Ultra-violet) : Susceptibility of Catalase-negative Bacteria to (Sidney Mittler and John A. Laverty), 793

Irradiation by Fast Neutrons : Effects of Daily, on Male Fertility (G. J. Neary, R. J. Munson and R. H. Mole), 256
Irradiation of Nucleic Acids with X-Rays in Aqueous Systems : Formation of Labile Phosphate Esters by (Dr. George Scholes and Dr. Joseph Weiss), 920
Irregularities in the Ionosphere : Wave Hypothesis of Moving (C. O. Hines), 980
Islamic Civilization and Culture (Library of the United States Congress and Princeton University Conference on), 822
Island (Oceanic) : Winter Cascading from an, and its Biological Implications (Brian P. Boden and Elizabeth M. Kampa), 426
Isotope Curves in Red Blood Cell Studies (D. S. Amatuzio and Robert L. Evans), 797
Isotopes : Fractionation of, by Distillation of some Organic Substances (P. Baertschi, Prof. W. Kuhn and H. Kuhn), 1018
Isotopes (Radioactive) : Instruments and Accessories for use with, 460
  Standards of (National Physical Laboratory), 676
Israeli Coast : A Cladoceran from the Plankton as a Possible Indicator for the Presence of the Nile Flood off the (Dr. B. Komarovsky), 937
*Isurus oxyrinchus*, in South African Waters, The Shark (Prof. J. L. B. Smith), 977

JACKSON-GWILT Medal and Gift of the Royal Astronomical Society awarded to J P. M. Prentice, 108
Jaffé Reaction : Determination of Creatinine by the (Dr. G. R. Harvey), 1125
Japanese Opisthobranchia, *review* by Dr. J. E. Forrest, 762
Jardins et des Parcs : Flore Illustrée des (Dr. P. Fournier), *review* by Sir Edward Salisbury, 493
Jellyfish *Aurellia aurita* Lamarck · An Action Potential from the Motor Nerves of the (Adrian Horridge), 400
Jet Noise in particular : Aeronautical Acoustics and (Acoustics Group of the Physical Society and the Royal Aeronautical Society Discussion on), 914
Jewett (Frank B.) Fellowship Awards (American Telephone and Telegraph Co.), 332
*Journal of Embryology and Experimental Morphology* (D R. Newth), 339
*Journal of the Institute of Metals*, Vol. 76, 1949–50 (edited by N. B. Vaughan), Vol. 77, 1950 (edited by N. B Vaughan), *review* by Dr. W. Hume-Rothery, 279
*Journal of Rational Mechanics and Analysis* (New quarterly published by the Graduate Institute for Applied Mathematics, Indiana University), 866
Joy and Verity, other Poems and a Poetic Drama (Dr. Marie C. Stopes), *review* by F. K., 900
Judgment · Factors affecting Choice and (D. Sheppard), 847 ; (Dr. R. G. Hopkinson), 848
Jute · Alternative Soft Fibres to, *review* by Sir Geoffrey Evans, 535
  Association of Glucose, Arabinose and Xylose in (Dr. D. B. Das, M. K. Mitra and J. F. Wareham), 613
Jute Substitute Fibres (A. E. Haarer), *review* by Sir Geoffrey Evans, 535

KAOLIN : Hardening of, on Rehydration (R. D. Hill), 567
Keratin · Iodination of (H. R. Richards and Prof. J B. Speakman), 751
α-Keratin Type . Compound Helical Configurations of Polypeptide Chains —Structure of Proteins of the (Prof. Linus Pauling and Prof. Robert B. Corey), 59
Kestrels : Short Circuits set up by (H. Lloyd), 243 ; (Miss Frances Pitt), 243
Keto-Enol Tautomerism of Solutions of 1 : 3-Diketo-2-phenyl-5-bromoindan : Thermochromism and (Prof. A. Schonberg, Dr. A. Mustafa and Dr. W. Asker), 222
Kičua : Bibliographie des langues aymará et (Paul Rivet et Georges de Créqui-Montfort), *review* by Dr. G. H. S. Bushnell, 1133
Kidney : Effect of Nervous Stimulation on the Arterio-Venous Oxygen and Carbon Dioxide Differences across the (Dr. Joseph H. Cort), 784
Kilimanjaro Area · Rock Engravings in the (H. A. Fosbrooke, sen., and Petro I. Marealle), 957
Kinematic Relativity and the Creator, *review* by Sir Harold Spencer Jones, 584
Kinetic Theory of the Chromosphere (Shotaro Miyamoto), 375
Kinetics : Reaction, of the Cytochrome System (Prof. H. Lundegårdh), 521
Kinetics (Electrochemical Thermodynamics and) . International Committee for—Meeting in London, 23
Kinetics of Reaction in Ethanol Solution from — 80° C. to + 20° C. (Dr. E. F. Caldin, G. Long and F. W. Trowse), 1124
Knowledge . Analysis and Synthesis of (Prof. P. Frank), 244 ; (President J. B. Conant), 244
  Diffusion of (Dr. L. Carmichael), 866
Kongwa : Reports on Experiments on Artificial Control of Rainfall at (D. A. Davies, D. Hepburn and H. Sansom), 829
Kossuth Prizes in Hungary for 1953, 1010
Kramer and Russell Effects with Single Crystals of Zinc (L. Grunberg and Dr. K. H. R. Wright), 890, *erratum*, 914
'Krilium', 198
'Krilium' and Synthetic Soil Conditioners (Prof. J. H. Quastel), 7
Kristallen : Fouriersynthese von, und ihre Anwendung in der Chemie (Prof. Werner Nowacki), *review* by Dr. C. H. Carlisle, 1131

LABILE Phosphate Esters : Formation of, by Irradiation of Nucleic Acids with X-Rays in Aqueous Systems (Dr. George Scholes and Dr. Joseph Weiss), 920
Laboratory Animals · The Supply of (Laboratory Animals Bureau Discussion on), 334
Lack of Water in a Land of Water (Dr. G. F. Makkink), 19
Lactate-oxidizing Systems in the Mycobacteria (Prof. N. L. Edson and P. B. Cousins), 702
Lactating Cows . Feeding of Seaweed Meal to (Dr. George Dunlop), 439
Lake District : Preservation of the, 31
Lake Waters : Occurrence of Hydroxylamine in, as an Intermediate in Bacterial Reduction of Nitrate (Motoharu Tanaka), 1160
Lambs (Dizygotic Twin) : Intolerance of, to Skin Homografts (G. H. Lampkin), 975
Lamellibranchia : The Ligament in the (G. Owen, E. R. Trueman and Prof. C. M. Yonge), 73
*Lamp, The*, No. 3 for 1952 (Standard Oil Co.), 246
Lancashire . Social Security and Unemployment in (Political and Economic Planning, Broadsheet No. 349), 382
Land of Water : Lack of Water in a (Dr. G. F. Makkink), 19
Land Bridges or Continental Drift : The South Atlantic— (Prof. Arthur Holmes), 669
Land Connections across the South Atlantic : The Problem of, with special reference to the Mesozoic (E. Mayr, M. Ewing, W. H. Bucher, K. E. Caster, C. O. Dunbar, M. Kay, G. G. Simpson, D I. Axelrod, T. Just, W. H. Camp, P. J. Darlington, Jun., A. E. Emerson, B. Schaeffer, D. H. Dunkle, E. H. Colbert and A. S. Romer), 669
Langmuir Adsorption as a Determinant of Conductivity in a Low-frequency Electric Discharge (A. P. Saxena, M. G. Bhatawdekar and N. A. Ramaiah), 929
Langues aymará et kičua : Bibliographie des (Paul Rivet et Georges de Créqui-Montfort), *review* by Dr. G. H. S Bushnell, 1133
Large-volume Measuring-Flasks (H. J. Elliott, Ltd.), 462
Larke (William J.) Medal for 1952 of the Institute of Welding awarded to J. Rennie, 377
Laterite : Vesicular (G ap Griffith), 530 ; (E. J. Wayland), 1079
Latin America : Bibliography of Science in, 109
  Scientific Institutions and Scientists in (Ecuador, Vol. 1), 110 ; (Argentine, Vol. 3), 110
  Social Anthropological Studies of, 686
Latin-American Course in Sao Paulo on Radioisotope Methodology, 289
Latitudes (High) : Abnormalities in the Ionosphere at (W. R. Piggott), 124
Latitudes (Northern) : Catalogue of Horrebow Star-Pairs for the Determination of, 505
Lattice Defects and the Electrical Resistivity of Metals (T. Broom), 1104
Laws of Addition and Substitution in Atomic Reactions of Halogens (Jean Adam, P. A. Gosselain and Prof. P. Goldfinger), 704
Laws of Friction (Dr. H. G. Howell), 220
Layers in Clay Minerals : Randomly Stacked (Dr. Douglas M. C MacEwan), 616
Layers of the Epicuticle of Insects : Homology of the (Prof. R Dennell and Dr. S. R. A. Malek), 298
Lead in a Sodium Acetate—Acetic Acid Bath : Electrolytic Polishing of (Elizabeth Jones and H. R. Thirsk), 843
Leaf (Tobacco Trashy) : Differential Fluorescence in Identification of (R. Johanson), 753
Leaf Macerates : Extra-Cellular Photosynthetic Reactions in (Dr. F. C. Gerretsen), 207
Leaf Miners : Biology of the (Prof. E. Martin Hering), *review* by V. W. Fowler, 763
Leaf Roll Virus Infection · Effect of, on the Soluble Nitrogen Composition of Potato Tubers (R. M. Allison), 573
*Leander serratus*: Neurosecretory Pathways in the Prawn (Dr. Francis G. W. Knowles), 131
Leaves : Apparatus for Infiltration of Liquids into (Arwyn Charles), 1166
Leaves (Cut) : Uptake of Dyes into (Arwyn Charles), 435
Lebesgue Integral (J. C. Burkill), *review* by Prof. H. T. H. Piaggio, 452
Leeuwenhoek Lecture for 1953 of the Royal Society (Dr. K. M. Smith), 290
Leibniz und das Reich der Gnade (Kurt Hildebrandt), *review* by F. I G. Rawlins, 992
Lemuroids : Miocene, of East Africa (Prof. W. E. Le Gros Clark and D. P. Thomas), 505
Lens : An Electrostatic Single, permitting Rigorous Calculation (Dr. Peter Schiske), 443
Lethal Dose of X-Rays : Therapeutic Action of Glutathione and Mercaptoethylamine against a (Prof. J. H. Maisin, G. Lambert, M. Mandart and H. Maisin), 971
Leucocytes · Fixation of Bacterial Products by Erythrocytes *in vivo* and by (Stephen V. Boyden), 402
Leukæmia and allied Diseases : Lady Tata Memorial Trust Awards for Research on, 1098
Library Co-operation in Great Britain, Report of the National Central Library and the Regional Library Bureaux (Robert F. Vollans), 1144
Library Work in the U.S.S.R. : Abstracting and (W. G. Cass), 555
Lice (Body) Forms of Insecticide-Resistance in Houseflies and (Dr. J. R. Busvine), 118
Liesegang Rings on Metallic Bases (Prof. Andrew VanHook and Edward J. Reardon), 177
Life : Mind and (A. G. Tansley), *review* by Dr. Clifford Allen, 364
  Raw Materials of (Dr. D. P. Riley and Dr. U. W. Arndt), 144
Life-cycle of *Halidrys siliquosa* Lyngb. : Incidence of Meiosis in the (Dr. Eveline Elliot and Betty Moss), 357
Life-history of *Fasciola gigantica* Cobbold 1856 (Dr. S. Brian Kendall and J. W. Parfitt), 1165
Life-history of *Gorgoderina vitelliloba* (Olsson), (E. Lees), 485
Ligament in the Lamellibranchia (G. Owen, E. R. Trueman and Prof. C. M. Yonge), 73
Light (Prof. R. W. Ditchburn), *review* by Dr. H. Lipson, 763
Light for Degree Students : Text-Book of, *review* by Dr. H. Lipson, 763
Light (Ultra-violet) : 'Parathion' and (Miss J. Payton), 355
Light Emission and Light Perception in Species of *Diadema* (Prof. N. Millott), 973
Light Microscopy · A New Method of (Prof. A. Wilska), 353, 698 ; (Dr. R. Barer), 697
Light Perception in Species of *Diadema* : Light Emission and (Prof. N. Millott), 973
Light Pulses from the Night Sky associated with Cosmic Rays (Dr. W. Galbraith and Dr. J. V. Jelley), 349
Light Scattering by very Stiff Chain Molecules (Prof. A. Peterlin), 259
Lilly (Eli) Travelling Fellowships in Medicine (Medical Research Council), 111
Lima Bean Phosphorylase : Effect of Added Primer on (Michinori Nakamura), 795
Limiting Products in the Photolysis of Acetaldehyde at High Intensity (M. A. Khan, Prof. R. G. W. Norrish and Dr. G. Porter), 513
Linear Transformations in *n*-Dimensional Vector Space (Prof. H. L. Hamburger and M. E. Grimshaw), *review*, 233

Linguistics (Structural): Methods in (Zellig S. Harris), review by Prof. Alan S. C. Ross, 1084
Linkage in Tobacco: A New (Dr. B. S. Kadam and B. Radhakrishnamurthy), 1028
Linnean Gold Medal for 1953 of the Linnean Society of London awarded to Prof. P. A. Buxton, 549, 1003
Lipid Metabolism (Biochemical Society Symposia No. 9, organized and edited by R. T. Williams), review, 494
Lipoids and Cholesterol in New-born Rats (Zdenek Dvorák), 432
Liquid Surfaces: Dynamic Potentials of Freshly Formed (Dr. C. C. Addison and D. Litherland), 393
Liquids: Apparatus for Infiltration of, into Leaves (Arwyn Charles), 1166
    Elasticity in (British Society of Rheology Symposium on), 778
    A New Precision Method for the Measurement of Ultrasonic Velocities in (Dr. R. Ramachandra Rao and K. Subba Rao), 1077
Liquids and Solids: Initiation and Growth of Explosion in (F. P. Bowden and A. D. Yoffe), review by Dr. James Taylor, 186
Lithium Iodide: Activation of, by Europium (Dr. James Schenck), 518
Litter: Microbiological Decomposition of (Prof. Jan Smit and Dr. K. T. Wieringa), 794
Liver: Histochemical Demonstration of Amine Oxidase in (C. M. Francis), 701
Liver (Isolated): Role of Choline in the Oxidation of Fatty Acids by the (Camillo Artom), 347
Liver (Mammalian): Anatomical and Physiological Evidence of Anastomosis of the Hepatic Artery and Hepatic Vein within the (Dr. W. H. Horner Andrews and Prof. B. G. Maegraith), 222
Liver (Mouse): Short-Term Carbon Dioxide Fixation in (Lemuel C. Leeper, Felix Friedberg and Lawrence M. Marshall), 748
Liver Ribonuclease: Effect of Sulphydryl Reactants on (Jay S. Roth), 127
Livers of Adult Rats: Percentage of Binucleate Cells in the (Marion F. Harrison), 611
Livestock Ranges: Management and Biology of, review, 97
Lobster Muscle: Mechanism of Hydrolysis of Adenosine Triphosphate catalysed by (Edith Clarke and D. E. Koshland, jun.), 1023
Logarithmic Tables to Base e and Base 10: Smithsonian (prepared by George Wellington Spenceley, Rheba Murray Spenceley and Eugene Rhodes Epperson), review by J. H. Pearce, 279
Logic: Medieval (Philotheus Boehner), review by A. D. R., 900
Logic of Experiment (Dr. J. Bronowski), 194
Lomonosov: Russia's (Boris N. Menshutkin), translated from the Russian by Jeannette Eyre Thal and Edward J. Webster, review by Prof. J. R. Partington, 138
London: The Proposed Science Centre for, 227
Long-chain Polymers: Effect of High-Energy Radiation on (Dr. A. Charlesby), 167
Long-Delay Ionospheric Echoes at 150 kc./s. (J. J. Gibbons, R. L. Schrag and Prof. A. H. Waynick), 444
Long-Distance Very-High-Frequency Propagation: Multiple Bursts of Signal in (G. A. Isted), 617
Longevity and Production in the Buffalo (Dr. K. A. Alim), 755
Lorentz Transformation (Dr. A. W. Ingleton), 618
Lost City of the Incas, the Story of Machu Picchu and its Builders (Hiram Bingham), review, 453
Lotaustralin: Inhibition of Populations of *Haemonchus contortus* in Sheep fed on White Clover (*Trifolium repens*) High in (J. H. Tetley), 311
Low-frequency Components: Atmospherics with Very (F. Hepburn and E. T. Pierce), 837
Loyalties: Conflicts of (Present Question Conference on), 665
Lucinacea (Eulamellibranchia): Function of the Foot in the (J. A. Allen), 1117
Luçon (Philippines): Les négritos de l'Ile de (Dr. E. Genet-Varcin), review by G. I. Jones, 811
*Lumbricus terrestris* L., Mull.: Spermatogenesis in (Dilys Rawson), 264
Luminosity generated by Shock Waves (R. N. Hollyer, jun., A. C. Hunting, Prof. Otto Laporte and E. B. Turner), 395
Lymnaeidae: Recent (Bengt Hubendick), 461
Lymphocytes: Effect of, on Ionizing Radiation (Prof. R. J. V. Pulvertaft, C. W. Wilson and Howard Jayne), 1157
Lysozyme: Inhibition and Activation of (Dr. E. Kaiser), 607

MACHINERY (Agricultural): A Survey of the Trade in (Commonwealth Economic Committee), 199
Machinery (Large-Scale Digital Calculating): Proceedings of a Second Symposium on (jointly sponsored by the Navy Department, Bureau of Ordnance and Harvard University), review by M. V. Wilkes, 54
Machinery and Implement Exhibition (Sports Turf Research Institute), 1142
Machines: Exhibition of Historic Books on (Science Museum, London), 820
Machu Picchu and its Builders: Lost City of the Incas, the Story of (Hiram Bingham), review, 453
Mackinnon Research Studentships of the Royal Society awarded to R. C. Jennison and Dr. F. K. Duxbury, 66
Macromolecules: Size and Shape of (Prof. H. W. Melville), 1087
Magellanic Clouds: Distances of the (Dr. A. D. Thackeray and A. J. Wesselink), 693
Magic and Medicine: Anglo-Saxon (J. H. G. Grattan and Charles Singer), review by Dr. Douglas Guthrie, 140
Magnesium Silicate: A Crystalline Hydrated, formed in the Breakdown of a Concrete Sea-wall (W. F. Cole), 354
Magnesium-Lithium $\beta$-Phase Alloys: Structure of (R. L. P. Berry and Prof. G. V. Raynor), 1078
Magnet Inhomogeneities in the Strong-focusing Synchrotron: Effect of (J. B. Adams, Dr. M. G. N. Hine and J. D. Lawson), 926
Magnetic Circuit: The (A. E. DeBarr), review by S. Weintroub, 1132
Magnetic Field: Damping of Turbulence by a (W. Murgatroyd), 217
Magnetic Materials used in Industry: Soft (A. E. DeBarr), review by S. Weintroub, 1132
Magnetic Measurements in Deep-Sea Investigations—Construction of Non-magnetic Containers (Dr. Niels Arley, Borge Lunn, Max Nielsen and Carl Norgaard), 383; Magnetic Investigations on the *Galathea* Expedition (Dr. Niels Arley, Povl Andreasen, Jorgen Espersen and Johannes Olsen), 384
Magnetic Properties of Rocks (Royal Astronomical Society and the Geological Society Geophysical Discussion on), 500
Magnetic Shielding: High-frequency Electric and (Y. Asami and A. Matsumoto), 957; (T. Matsumoto), 957
Magnetic Storms (Terrestrial): Radio Echoes observed during Aurora and, using 35 and 74 Mc./s. Waves Simultaneously (Prof. L. Harang and B. Landmark), 1017
Maillard Reaction in Fish Muscle: Ribose and the (Dr. H. L. A. Tarr), 344
Makdougall-Brisbane Prize for 1950–52 of the Royal Society of Edinburgh awarded to Prof. E. M. Wright, 867
Malabar Coast: Phosphate Content of the Mudbanks along the (G. Seshappa), 526
Malayan Timber Trees: Pocket Check List of, 461
Male Cones in *Pinus sylvestris*: Experimental Induction of (Dr. P. F. Wareing), 47
Malignant Hepatomas: Rapid Production of, by Simultaneous Administration of Tannic Acid and 2-Acetylaminofluorene (Dr. Martha Mosonyi and Dr. Béla Korpássy), 791
Malonate: Inhibitory Effect of, on the Respiration of Brain Tissue, with special reference to the Potassium Effect (Y. Kimura and T. Niwa), 881
Mammalian Liver: Anatomical and Physiological Evidence of Anastomosis of the Hepatic Artery and Hepatic Vein within the (Dr. W. H. Horner Andrews and Prof. B. G. Maegraith), 222
Mammals: Fossil, of Africa, No. 4, Miocene Anthracotheriidae from East Africa (D. G. MacInnes), 505; No. 5, The Miocene Lemuroids of East Africa (Prof. W. E. Le Gros Clark and D. P. Thomas), 505
Mammals (Marine): Birds and Wild Animals, including (H. Trevor Jones), review by T. H. H., 143
Man: Effect of Cortisone on Tissue Potentials in (Geoffrey E. Loxton and David Le Vay), 524
    Habitat, Vegetation and (Prof. W. H. Pearsall), 367
    Impact of, on British Wild Life, review by Dr. L. Harrison Matthews, 714
    Metals in the Service of (A. R. Hutchinson), 1053
    Speaking of (Dr. Abraham Myerson), review by Dr. Clifford Allen, 232
Man-power Problems: Overseas Development and, 405
Management: Three Studies in (Jerome F. Scott and R. P. Lynton), 49
Management and Conservation of Vegetation in Africa, review by Sir Edward Salisbury, 496
Manganese Requirements of Tomato Plants at Different Phases of Growth (M. Bakr Ahmed and Prof. E. S. Twyman), 438
Manganous Ions: Interaction of, with Enolase (Dr. Bo G. Malmstrom), 392
Marine Alga *Spongomorpha*: Variability in the X-Ray Diagram of the Cell Walls of the (E. Nicolai and Dr. R. D. Preston), 752
Marine Animals: A New Technique for Microscopic Preparations of small (Jessie J. Rankin), 35
Marine Biology: Recent (Dr. N. B. Eales), 24
Marine Biology Research in Great Britain (Dr. N. B. Eales), 828
Marine Biology or Oceanography: Grants in aid of Research in (Challenger Society), 1054
Marine Mammals: Birds and Wild Animals, including (H. Trevor Jones), review by T. H. H., 143
Marine or Freshwater Science: Grants for Research in (Development Commission), 729
Materials of Life: Raw (Dr. D. P. Riley and Dr. U. W. Arndt), 144
Mathematical Statistics and Probability: Proceedings of the Second Berkeley Symposium on (edited by Jerzy Neyman), review by Prof. M. G. Kendall, 410, 463
Mathematical Tables: Depository of Unpublished (Royal Society), 1140
Mathematics: Guido Fubini Prize in, 245
    School, To-day and To-morrow (K. S. Snell), 778
Mathematics (Applied): The Spirit of (Prof. C. A. Coulson), 912
Mathematics at Dundee, 1051
Mathematics at the Royal Technical College, Glasgow, 287
Mathematischen Wissenschaften: Wörterbuch der (Dr. Leo Herland) Band I, Deutsch–Englisch, review by Dr. L. S. Goddard, 811
Mather Lecture for 1953 of the Textile Institute (Dr. C. M. Whittaker), 377
Mating in *Taeniorhynchus* (*Mansonioides*) *uniformis* (Theobald): Nocturnal (Dr. S. H. Jayewickreme), 577
Matter: Awkward Properties of, review by D. R. Wilkie, 53
'Maxwell's Spot' in Colour Vision, review by Prof. W. D. Wright, 5
Measurement of Ultrasonic Velocities in Liquids: A New Precision Method for the (Dr. R. Ramachandra Rao and K. Subba Rao), 1077
Measuring Sperm Speeds: A New Method of (Lord Rothschild), 512
Measuring-flasks: Large-volume (H. J. Elliott, Ltd.), 462
Mechanical and Electrical Engineering Failures: Analysis of (Prof. F. C. Thompson), 510
Mechanics: Classical (Dr. D. E. Rutherford), review by Prof. H. T. H. Piaggio, 992
Mechanism of Electropolishing (Dr. P. R. Rowland), 931
Mechanism of Government in a Democracy, 183
Mechanism of Hydrolysis of Adenosine Triphosphate catalysed by Lobster Muscle (Edith Clarke and D. E. Koshland, jun.), 1023
Mechanism of Ion Absorption by Roots (Emanuel Epstein), 83
Mechanism of Protoplasmic Movement (Prof. William Seifriz), 1136
Mechanisms of Biological Correlations: Variability of Internal Environment and the (Eugène Schreider), 339
Medical Applications: Scintillation Counting and its (Prof. W. V. Mayneord), 813
Medical Research: Best Memorial Fellowships for (Awards), 1097
Medical Science: French Government Exchange Scholarships in (Medical Research Council), 111
Medical and other Biological Students: Statistics for (L. Bernstein and M. Weatherall), review, 278
Medicine: Anglo-Saxon Magic and (J. H. G. Grattan and Charles Singer), review by Dr. Douglas Guthrie, 140
    Eli Lilly Travelling Fellowships in (Medical Research Council), 111
    Rockefeller Travelling Fellowships in (Medical Research Council), 111
Medicine (Aviation): Some Future Problems in, review by Dr. K. E. Spells, 51
Medicine (Popular): Religious Dances in the Christian Church and in (Prof. E. Louis Backman), translated by E. Classen, review by M. C. Burkitt, 667
Medicine of the Upper Atmosphere: Physics and (edited by Dr. Clayton S. White and Brig.-General Otis O. Benson, Jr.), review by Dr. K. E. Spells, 51
Medieval Logic (Philotheus Boehner), review by A. D. R., 900

- Meiosis in the Life-cycle of *Halidrys siliquosa* Lyngb.: Incidence of (Dr. Eveline Elliot and Betty Moss), 357
- Melanin: Effects of some Chelate Compounds upon the Formation *in vitro* of (Saburo Iwata and Shuzo Ishida), 303
- Melanophore Expanding (B) Hormone of the Pituitary: Relation of Adrenocorticotrophin (ACTH) to the (Prof. H. Waring and B. Ketterer), 862
- Meldola Medals for 1952 of the Society of Maccabaeans awarded to T. L. Cottrell and Dr. B. C. L. Weedon, 726
- Mercaptoethylamine: Therapeutic Action of Glutathione and, against a Lethal Dose of X-Rays (Prof. J. H. Maisin, G. Lambert, M. Mandart and H. Maisin), 971
- Merck Fellowships of the National Research Council, Ottawa: Awards, 1054
- Meridian: The Greenwich, 1140
- Merino (Australian): Follicle Development in the (P. G. Schinckel), 310
- Meson Intensity: Daily Variation of, and its Possible Solar Origin (V. Sarabhai, U. D. Desai and R. P. Kane), 122
- Meson Production: Multiple (Dr. L. S. Kothari), 309
- $\mu$-Meson Capture: X-Rays accompanying (Columbia University 'Press Release' on), 1097
- Mesozoic: The Problem of Land Connections across the South Atlantic, with special reference to the (E. Mayr, M. Ewing, W. H. Bucher, K. E. Caster, C. O. Dunbar, M. Kay, G. G. Simpson, D. I. Axelrod, T. Just, W. H. Camp, P. J. Darlington, Jun., A. E. Emerson, B. Schaeffer, D. H. Dunkle, E. H. Colbert and A. S. Romer), 669
- Metabolic Processes: The Role of Vitamins in (Nutrition Society Symposium on), 456
- Metabolism: Carbohydrate, in Protozoa and Metal-binding Substances (J. F. Ryley), 747
  - Haemoglobin (Section of Pathology of the Royal Society of Medicine Symposium on), 464
  - Lipid (Biochemical Society Symposia No. 9, organized and edited by R. T. Williams), *review*, 494
  - Nitrogen, of Apple Trees (E. G. Bollard), 571
  - Phosphorus, a Symposium on the Role of Phosphorus in the Metabolism of Plants and Animals (sponsored by the McCollum-Pratt Institute of the Johns Hopkins University), Vol. I (edited by William D. McElroy and Bentley Glass), *review* by Dr. T. Mann, 808
- Metabolism of Microorganisms: The Integration of Research on the Nutrition and (Dr. D. D. Woods), 290
- Metabolites: The Determination of Adrenal Cortical Steroids and their (Society for Endocrinology Symposium on), 777
- Metacercaria: A New Trematode, from the Eyes of Trout (Dr. M. B. Lal), 130
- Metal in Solution: Determination of the Relative Electrode Potential of an Uncharged (Dr. J. O'M. Bockris and R. Parry-Jones), 930
- Metal Cations: Hydration of (Dr. E. Glueckauf and G. P. Kitt), 1010
- Metal Ion Catalysis of the Decarboxylation of Oxalo-Acetic Acid (Dr. R. J. P. Williams), 304
- Metal Oleates: Dipole Moments of (A. Gilmour, S. M. Nelson and Dr. R. C. Pink), 1075
- Metal Physics Work of the Division of Tribophysics, C.S.I.R.O. (Dr. W. Boas), 908
- Metal Single Crystals: A Special Kind of Growth Structure in (Dr. F. Blaha), 650
- Metal-binding Substances: Carbohydrate Metabolism in Protozoa and (J. F. Ryley), 747
- Metal-to-Metal Bonds in Cupric and Chromous Acetate: X-Ray Evidence for (J. N. van Niekerk and R. F. L. Schoening), 36
- Metal/Mould Interfaces: Measurement of Temperatures of (D. V. Atterton and D. H. Houseman), 980
- Metallic Bases: Liesegang Rings on (Prof. Andrew VanHook and Edward J. Reardon), 177
- Metallurgy—Craft and Science (Prof. A. G. Quarrell), 779
- Metals: A Dislocation Model for the Study of Boundary Phenomena and Deformation of (W. I. Pumphrey), 218
  - Emission Spectroscopic Determination of, in Non-Metallic Samples (American Association of Spectrographers Symposium on), 66
  - Lattice Defects and the Electrical Resistivity of (T. Broom), 1104
  - Testing of Bearing Properties of (Dr. D. Tabor), 827
  - The Use of Electrons for the Examination of (University of Cambridge in co-operation with the Institute of Metals Summer School in), 867
- Metals (Alkali): Resonance Radiation from Hydrogen Flames containing (C. G. James and Dr. T. M. Sugden), 428
- Metals (Cold-worked): Softening of, under Cyclic Strains (N. H. Polakowski), 173
- Metals (Sleeve Bearing): Some Experiments with (Dr. Borge Lunn), 827
- Metals in the Service of Man (A. R. Hutchinson), 1053
- Metals and Alloys (Non-Ferrous): The Cold Working of (Institute of Metals Symposium on Metallurgical Aspects of), *review* by Dr. A. J. Kennedy, 992
- Metamathematics: Introduction to (Prof. Stephen Cole Kleene), *review* by F. I. G. Rawlins, 1039
- Metaphases' ('Three-Group'): Production of, in the Bone-Marrow of the Golden Hamster (Dr. R. Parmentier), 1029
- *Metatetranychus ulmi* (Koch): Toxicity of Chlorinated Phenyl Benzenesulphonates to Winter Eggs of the Fruit Tree Red Spider Mite (Dr. A. H. M. Kirby and R. P. Tew), 479
- Meteorological Changes in the Period January–April 1949: Geophysical and (Dr. W. J. G. Beynon and G. M. Brown), 967; (R. P. Waldo Lewis and D. H. McIntosh), 969
- Meteorological Expedition to the British West Indies, 419
- Meteorological Service: German, of the U.S. Zone, 331
- Methionine: Degradation of, by Hydrogen Peroxide (Yoshihiko Matsuo), 1021
- Methodology Reviews, 1941–1950: Statistical (edited by Prof. Oscar Krisen Buros), *review*, 496
- Methyl *bis* (beta-Chloroethyl) Amine Hydrochloride: Effects of, on Haploid and Diploid Embryos of *Habrobracon* (A. M. Clark and W. C. Besser, jun.), 178
- 4-Methyl-D-glucuronic Acid in *Eucalyptus regnans* Wood: Identification of (C. M. Stewart and D. H. Foster), 792
- Methyl Methacrylate Polymer: Breakdown of, by High-Energy Radiation (Dr. A. Charlesby and M. Ross), 1153
- Methyl Palmitate and Methyl Stearate in the Microwave Region: Resonance Absorption in Liquid (T. J. Buchanan), 695
- Methyl Stearate in the Microwave Region: Resonance Absorption in Liquid Methyl Palmitate and (T. J. Buchanan), 695
- Methylene Blue in staining of Nerve Fibres: Hyaluronidase as an Adjuvant to (Ian A. McGregor), 1070
- Methylenedioxy Groups of the Alkaloid Protopine: Origin of the (M. Sribney and Prof. S. Kirkwood), 931
- Mexican Municipio: Quiroga, a (Donald D. Brand), 686
- Micro-beam Technique: A Simple X-Ray (L. C. Spark), 695
- Microbial Activity in Soils: Use of the Warburg Respirometer to study (F. E. Chase and Dr. P. H. H. Gray), 481
- Microbial Genetics at the University of Glasgow, 66
- Microbial Growth and its Inhibition (World Health Organization, Monograph Series No. 10), 155
- Microbiological Assay: Differentiation of Vitamin $B_{12}$ Active Compounds by Ionophoresis and—Ionophoresis (Dr. E. S. Holdsworth), 148; Microbiological Tests (J. E. Ford), 149; Occurrence of the various Vitamin $B_{12}$ Active Compounds (J. E. Ford, Dr. E. S. Holdsworth, Dr. S. K. Kon and Dr. J. W. G. Porter), 150
- Microbiological Decomposition of Litter (Prof. Jan Smit and Dr. K. T. Wieringa), 794
- Microbiological Methods: Recent Advances in (Society for Applied Bacteriology and the Microbiological Group of the Society of Chemistry and Industry Discussion on), 507
- Microbiology: Sixth International Congress of, 462
- *Microbiology, Applied*, No. 1 (Society of American Bacteriologists), 638
- Microcalorimeter: The Tian–Calvet, in Seed Germination Studies (Prof. H. Prat), 24
- Micro-Climatology: Bases of (Sir David Brunt), 322
- Microdissection: Electron Microscope and (R. Bovey), 155
- Micronesia: Insects of, 638
- Microorganisms: The Integration of Research on the Nutrition and Metabolism of (Dr. D. D. Woods), 290
- Microscope: An Interferometer, for the Accurate Measurement of Optical Thickness (J. Dyson), 743
- Microscope Slides: A New Method in Staining Bacteria on (Prof. P. H. H. Gray), 1030
- Microscopic Preparations of Small Marine Animals: A New Technique for (Jessie J. Rankin), 35
- Microscopical Identification of the Constituents of Coal Dust (Dr. R. G. H. B. Boddy), 928
- Microscopical Methods: Developments in (Industrial Section of the Royal Microscopical Society, in co-operation with the Optical Group of the Physical Society, the Physical Methods Group of the Society of Public Analysts and other Analytical Chemists, and the Industrial Spectroscopy Group of the Institute of Physics, Discussion on), 245, 730
- Microscopy: Shadow, for Measurement of Height (Prof. S. Tolansky), 564
- Microscopy (Light): A New Method of (Prof. A. Wilska), 353, 698; (Dr. R. Barer), 697
- Microscopy of Plant Ashes (Dr. J. W. Fairbairn), 1008
- Microsomal Particles of Normal Cow's Milk (Dr. R. K. Morton), 734
- Microwave Region: Resonance Absorption in Liquid Methyl Palmitate and Methyl Stearate in the (T. J. Buchanan), 695
- Microwave Spectrum and Structure of Iodosilane (Dr. A. H. Sharbaugh, G. A. Heath, L. F. Thomas and Dr. J. Sheridan), 87
- Middle East: Scientific Papers published in the (Middle East Science Co-operation Office), List No. 7, 201
- Migration (Spring): Patterns of (T. H. Hawkins), 25
- Milk (Coconut): Dividing Nuclei in (Miss Mridula Dutt), 799
- Milk (Cow's): Differences in the Vitamin $B_{12}$ Content of, during the Last Month Indoors and the First Week at Pasture (E. E. van Koetsveld), 483
  - Microsomal Particles of Normal (Dr. R. K. Morton), 734
- Milk (Fresh Whole): Quantitative Estimation of the Total Solids in, by Oxidimetry (Arthur G. Leggatt), 1028
- Milk (Whale's): Composition of (J. C. D. White), 612
- Milking Cows: Effect of a Copper Supplement to the Rations of (Dr. George Dunlop), 356
- Milngavie, Dumbartonshire: *Amoeba discoides* recorded for (Sister Monica Taylor), 225
- Mind (Child's): Formation of Symbols in the, *review* by Prof. John Cohen, 450
- Mind (Modern): Descartes and the (Prof. Albert G. A. Balz), *review* by L. J. Beck, 277
- Mind and Life (A. G. Tansley), *review* by Dr. Clifford Allen, 364
- Mineral Resources in the United States: Development of, 155
- Mineralized Plant Fossils: Staining and Plastic Embedding of small (Dr. Henning Horn af Rantzien), 516
- Minerals (Clay): Randomly Stacked Layers in (Dr. Douglas M. C. MacEwan), 616
- Minerals (Feldspar): Investigation at Cambridge of the, 636
- Mining at the Imperial College, London, 153
- Miocene Anthracotheriidae from East Africa (D. G. MacInnes), 505
- Miocene Lemuroids of East Africa (Prof. W. E. Le Gros Clark and D. P. Thomas), 505
- Mitochondria (Isolated): Histochemical Detection with Ditetrazolium Chloride of some Enzymatic Activities in (Dr. Mario Umberto Dianzani), 125
- Mitochondria and Cytoplasmic Double Membranes: Electro Microscopy of (Dr. Fritiof S. Sjostrand), 30
- Mitochondrial Distribution in Saccharomyces (Dr. Balaji D. Mundkur), 793
- Mitochondrial Membrane (J. L. Farrant, Dr. R. N. Robertson and Miss M. J. Wilkins), 401
- Model for Arches in the Solar Corona: A Theoretical (Dr. J. W. Dungey), 618
- Models and Molecules (Prof. J. H. Hildebrand), 462
- Modernity: Descartes, the Father of, *review* by L. J. Beck, 277
- Molars/Premolars in Perissodactyls: The Ratio (Dr. P. L. Pirlot), 972
- Molecular Architecture of Plant Cell Walls (Dr. R. D. Preston), *review* by Dr. K. Wilson, 98
- Molecular Chains: Mean Square Radius of randomly coiled (Dr. R. A. Sack), 310
- Molecular Configuration of Dextrans in Aqueous Solution (Dr. A. G. Ogston and E. F. Woods), 221

Molecular Complexes of Nitro-compounds: Emission of (R. Foster and D. Ll. Hammick), 40
Molecular Compounds of the Quinhydrone Type (Dr. S. C. Wallwork and T. T. Harding), 40
Molecular Sandwich: *Bis*-cyclopentadienyl Iron, a (J. D. Dunitz and L. E. Orgel), 121
Molecular Structure: Recent Advances in the Study of (Société de Chimie physique Discussion on), 914
Molecular Structure of Nucleic Acids—A Structure for Deoxyribose Nucleic Acid (J. D. Watson and F. H. C. Crick), 737; Molecular Structure of Deoxypentose Nucleic Acids (Dr. M. H. F. Wilkins, Dr. A. R. Stokes and H. R. Wilson), 738; Molecular Configuration in Sodium Thymonucleate (Rosalind E. Franklin and R. G. Gosling), 740
Molecular Structure and Spectroscopy (Symposium at the Ohio State University), 201
Molecular Weight Determination by Thermistors (Dr. S. B. Kulkarni), 219
Molecule (Haemoglobin): Position of Haems in the (Prof. D. Keilin), 922
Molecules: Models and (Prof. J. H. Hildebrand), 462
Molecules (Adsorbed): Measurement of Activated Diffusion of (R. A. W. Haul), 519
Molecules (Polar). Dielectric Relaxation Time of, in Solution (Nora E. Hill), 836
Molecules (Very Stiff Chain): Light Scattering by (Prof. A. Peterlin), 259
Molecules (Large) and Colloidal Particles. Some Applications of the Separation of (Prof. A. Tiselius), 290
Molluscs (British). Shell Regeneration in some (Dr. L. E. Wagge and T. Mittler), 528
Molybdenum in Herbage: Excess of, as a Possible Contributory Factor in Equine Osteodystrophia (Dr. T. Walsh and Dr. L. B. O'Moore), 1166
Molybdenum Fertilizers on Berseem (*Trifolium alexandrinum*): Effect of Boron and (N. P. Datta and H. Gurubasava Raj), 134
Molybdenum Levels in Herbage on Acid Soils: High (Dr. T. Walsh, M. Neenan and Dr. L. B. O'Moore), 1120
Monkey, *Cercopithecus ascanius schmidti*: The African Red-tailed (Dr. A. J. Haddow), 18
Monkey, *Procolobus verus*: The African Olive Colobus (W. C. Osman Hill), 18
Monolayers (Protein). Formation of Fibres from (Dr. J. Gordin Kaplan and M. J. Fraser), 559
Moolelo Hawaii (Hawaiian Antiquities), (David Malo), translated from the Hawaiian by Dr. Nathaniel B. Emerson, second edition, *review* by Dr. G. H. S. Bushnell, 764
Morphogenesis. Phylogeny and (Prof. C. W. Wardlaw), *review* by Prof. W. H. Pearsall, 230
Morphological Evidence for Subspecific Differences between Naples and Plymouth Populations of *Ophryotrocha puerilis*: Genetic and (Dr. Guido Bacci and Dr. Marcello La Greca), 1115
Morphology of Crystalline Synthetic Polymers (A. Keller), 170
Morphology and Antigenic Structure in Bacteria: Some Relationships between (Dr. K. A. Bisset), 1118
Mortality from Experimental Burns: Effect of Hyaluronidase on the (Edith Rosenberg, C. R. McComb, A. W. Farmer and W. R. Franks), 431
Mosquito Larvae: Predacious (James G. Halcrow), 1167
Motor Nerves of the Jellyfish *Aurelia aurita* Lamarck: An Action Potential from the (Adrian Horridge), 400
Moulds (Slime): Aggregation in Cellular—*in vitro* Isolation of Acrasin (B. M. Shaffer), 975
Mouse (House): Affinity, a New Genetic Phenomenon in the—Evidence from Distant Crosses (Donald Michie), 26; Evidence from within Laboratory Stocks (Mrs. Margaret E. Wallace), 27
  A Dominant Sex-linked Mutation in the (E. D. Garber), 332, (Dr. D. S. Falconer), 638
Mouse Epidermis: Latent Carcinogenic Action of Beta-Irradiation on (Dr. Philippe Shubik, A. Robert Goldfarb, A. C. Ritchie and Hermann Lisco), 934
Mouse Liver: Short-Term Carbon Dioxide Fixation in (Lemuel C. Leeper, Felix Friedberg and Lawrence M. Marshall), 748
Mouth-parts of Aphids: A Method of obtaining Phloem Sap via the (Dr. J. S. Kennedy and T. E. Mittler), 528
Moving Irregularities in the Ionosphere: Wave Hypothesis of (C. O. Hines), 980
Moving-Boundary Electrophoresis of Colloidal Electrolytes using Concentration Boundaries (Dr. Hira Lal), 175
Mt. Wrangell, Alaska: Joint Expedition to (New York University and the University of Alaska), 1140
Mucin Secretion in the Ewe's Oviduct (Dr. B. Hadek), 750
Mudbanks along the Malabar Coast. Phosphate Content of (G. Seshappa), 826
Multi-spots in Paper Chromatograms (Dr. A. S. Curry), 1026
Multiple Bursts of Signal in Long-Distance Very-High-Frequency Propagation (G. A. Isted), 617
Multiplication Process: A New Electron (W. L. Harries and Dr. A. von Engel), 517
Murchison Grant of the Royal Geographical Society awarded to G. B. Stigant, 636
*Murex* from the Red Sea (Sister Monica Taylor), 756
Muscle. Effect of Enforced Exercise on Myoglobin Concentration in (Dr. R. A. Lawrie), 1069
Muscle (Carp): Myoglobin from (G. Hamoir), 345
Muscle (Fish): Ribose and the Maillard Reaction in (Dr. H. L. A. Tarr), 344
Muscle (Lobster): Mechanism of Hydrolysis of Adenosine Triphosphate catalysed by (Edith Clarke and D. E. Koshland, jun.), 1023
Muscle Model: Heat Exchanges of a (Dr. M. G. M. Pryor), 213
Museum Collections of British Birds and Eggs (Colin Matheson), 957
Museums: Fakes and Forgeries in (Dr. H. J. Plenderleith), 18
Museums and Education (Dr. D. A. Allan), 1004
Mushroom: Second International Conference on the Biology and Cultivation of the, 506
Mustard Gas: Chromosomal Re-arrangements in the Progeny of *Drosophila* Males treated with (Dr. M. Mehtab), 262
Mutants of *Neurospora*: Inhibition Effects in Back-Mutation Tests with (C. M. Stevens and A. Mylroie), 179
Mutation: Spontaneous and Induced (Sir Cyril Hinshelwood), 270
Mutation in the House Mouse: A Dominant Sex-linked (E. D. Garber), 332; (Dr. D. S. Falconer), 638
Mycelium of *Boletus variegatus* (Sw.) Fr.: Transfer of Labelled Nitrogen from Glutamic Acid to Pine Seedlings through the (Prof. Elias Melin and Harald Nilsson), 134
Mycobacteria: Lactate-oxidizing Systems in the (Prof. N. L. Edson and F. B. Cousins), 702
Mycorrhizal Strawberry Roots: Fructifications associated with (Barbara Mosse), 974
Myoglobin from Carp Muscle (G. Hamoir), 345
Myoglobin Concentration in Muscle: Effect of Enforced Exercise on (Dr. R. A. Lawrie), 1069
Myxoma and Fibroma Viruses. Classification of (Prof. Frank Fenner), 562

NANNOPLANKTON: Significance of (Sigmund M. Miller and Hilary B. Moore), 1121
Naples and Plymouth Populations of *Ophryotrocha puerilis*: Genetic and Morphological Evidence for Subspecific Differences between (Dr. Guido Bacci and Dr. Marcello La Greca), 1115
Narcotics and Biological Acetylations (W. J. Johnson and Prof. J. H. Quastel), 602
National Parks in Great Britain, 358
Nationalized Industries. Research in, 447
Nationalized Industry: Problems of (edited by Prof. William A. Robson), 448
Natural Philosophy at Oxford, 911
Natural Science in Secondary Schools: Teaching of (W. L. Sumner), 685
Nature Conservancy (Linnean Society Discussion on the), 590
Navigation To-day (Exhibition at the Science Museum, London), 463
Nebulae (Southern Elliptical): Surface Photometry of (Dr. David S. Evans), 913
Nectar: Contamination of, with the Systemic Insecticide 'Schradan' (Dr. G. D. Glynne Jones and Dr. W. D. E. Thomas), 263
Negative-Ion Formation in Gases of High Dielectric Strength (Dr. J. W. Warren, J. Marriott and Dr. J. D. Craggs), 514
Négritos de l'Ile de Luçon (Dr. E. Genet-Varcin), *review* by G. I. Jones, 811
Neo-Positivism. The Birth of, *review* by F. L. G. Rawlins, 947
*Nereis succinea* (Leuckart) off the East Coast of Canada: Swarming of (C. Berkeley and E. Berkeley), 847
Nerve Fibres: Hyaluronidase as an Adjuvant to Methylene Blue in staining of (Ian A. McGregor), 1070
  Silver Impregnation of (A. Peters), 613
Nerve Fibres in the Adrenal Cortex of the Rat (J. D. Lever), 882
Nerve-Muscle Junction: Statistical Nature of 'Facilitation' at a Single (Dr. J. del Castillo and Prof. B. Katz), 1016
Nerves (Motor). An Action Potential from the, of the Jellyfish *Aurelia aurita* Lamarck. (Adrian Horridge), 400
Nervous Stimulation: Effect of, on the Arterio-Venous Oxygen and Carbon Dioxide Differences across the Kidney (Dr. Joseph H. Cort), 784
Nervous System (Central and Peripheral). Distribution of Substance *P* in the (Dr. Bengt Pernow), 746
Neurosecretory Pathways in the Head of Crustaceans, Insects and Vertebrates (Prof. Bertil Hanström), 72
Neurosecretory Pathways in the Prawn, *Leander serratus* (Dr. Francis G. W. Knowles), 131
*Neurospora*: Inhibition Effects in Back-Mutation Tests with Mutants of (C. M. Stevens and A. Mylroie), 179
Neurotic in Society: The, *review* by Dr. Clifford Allen, 667
Neutron Detector: A Fast and Efficient (John Kirkbride), 564
Neutrons (Fast): Effects of Daily Irradiation by, on Male Fertility (G. J. Neary, R. J. Munson and R. H. Mole), 256
Neutrons and Protons in Atomic Nuclei: Difference between the Density Distribution of (Prof. P. Gombás), 979, *erratum*, 1054
New Zealand. The Gannet in (C. A. Fleming and K. A. Wodzicki), 504
Newcomb Cleveland Prize of the American Association for the Advancement of Science awarded to Dr. Andrew M. Gleason, 65
Newton's 'Principia' in the United States, Canada and Mexico: A Survey of the Number of Copies of (Frederick E. Brasch), 18
Newton's Work on Geometrical Optical Aberrations (Prof. A. C. S. van Heel), 305
'Newtonian' Time in General Relativity (Prof. P. C. Vaidya), 260
Nicotine together with Hyoscine in *Duboisia myoporoides* R. Br.: Occurrence of (K. Loftus Hills, W. Bottomley and P. L. Mortimer), 435
*iso*Nicotinic Acid Hydrazide: Crystal Structure of (L. H. Jensen), 217
Nigeria: Oil Palm Research in, 595
Nile Flood off the Israeli Coast: A Cladoceran from the Plankton as a Possible Indicator for the Presence of the (Dr. B. Komarovsky), 937
Nineteenth Century (Early): Scientific Thought of the, *review* by V. A. Eyles, 714
Nisin: Sulphur-containing Amino-acids of (G. G. F. Newton, Dr. E. P. Abraham and Dr. N. F. Berridge), 606
Nitrate: Occurrence of Hydroxylamine in Lake Waters as an Intermediate in Bacterial Reduction of (Motoharu Tanaka), 1160
Nitration in an Aromatic Nucleus: Simultaneous Sulphonation and (A. Bryson and J. L. Garnett), 41
*N*-Nitration and *C*-Nitration by the Nitronium Ion (Eileen L. Blackall and Prof. E. D. Hughes), *erratum*, 156
Nitric Oxide: Effect of, on the Thermal Decomposition of Ethyl Nitrate (Dr. F. H. Pollard, H. S. B. Marshall and A. E. Pedler), 1154
Nitro-compounds: Emission of Molecular Complexes of (R. Foster and D. Ll. Hammick), 40
Nitrogen (Labelled). Transfer of, from Glutamic Acid to Pine Seedlings through the Mycelium of *Boletus variegatus* (Sw.) Fr. (Prof. Elias Melin and Harald Nilsson), 134
Nitrogen (Liquid): Tensile Strength of (Prof. A. D. Misener and F. T. Hedgcock), 835
Nitrogen Bands excited in a Nitrogen Ozonizer: Effect of Irradiation on the Intensity Distribution of the Second Positive (Dr. S. K. Asundi and N. Appalanarasimham), 86
Nitrogen Composition of Potato Tubers: Effect of Leaf Roll Virus Infection on the Soluble (R. M. Allison), 573
Nitrogen Metabolism of Apple Trees (E. G. Bollard), 571
Nitrogen Mustard: Effect of, on an Inherited Character in the Rat (P. Armitage), 1117

Nitrogen Ozonizer : Effect of Irradiation on the Intensity Distribution of the Second Positive Nitrogen Bands excited in a (Dr. S. K. Asundi and N. Appalanarasimham), 86
Nitronium Ion : N-Nitration and C-Nitration by the (Eileen L. Blackall and Prof. E. D. Hughes), *erratum*, 156
Nitroso Compounds : Perfluoroalkyl (Dr. Joan Banus), 173
Nobel Prize-winners in Physics : Meeting of, 822, 1098
Nodulation of *Trifolium ambiguum* : Effect of Grafting on (F. W. Hely, Ch. Bonnier and P. Manil), 884
Noise from Aircraft at Supersonic Speeds (C. H. E. Warren), 214 ; (E. W. Barton), 215 ; (P. Rothwell), 215 ; (Dr. E. Esclangon), 827
Nomads of the Long Bow, the Siriono of Eastern Bolivia (Allan R. Holmberg), 686
Non-Effect of Hyaluronidase on the Spread of Œstrone (Mary E. Bromhead (Mrs. Webster) and Prof. Paul G. 'Espinasse), 46
Non-Electrolytes : Equilibrium Properties of Solutions of (Faraday Society General Discussion on), 462
Non-Equilibrium States : Summer Course in the Thermodynamics of Equilibrium and (Massachusetts Institute of Technology), 729
Non-specific Precipitation of Proteins by Polyhaptenic Dyes (Dr. John L. Morrison), 346
Noradrenalin in the Human Foetal Adrenals and Aortic Bodies Determination of Adrenalin and (Kalevi Nieminevа and Aimo Pekkarinen), 436
Noradrenalin from the Suprarenal Medulla : Influence of the Blood Glucose-Level on the Secretion of Adrenalin and (Hans Dunér), 481
North America (Eastern) : Cytology of the *Dryopteris spinulosa* Complex in (Prof. I. Manton and S. Walker), 1116
Northern Latitudes . Catalogue of Horrebow Star-Pairs for the Determination of, 505
*Nosema apis* (Zander) : Effect of Fumagillin upon (Dr. L. Bailey), 212
Nuclear Motion : Investigation of, by Electron Diffraction (L. S. Bartell and Prof. L. O. Brockway), 978
Nuclear Physics . Experimental and Theoretical (University of Glasgow in co-operation with the International Union of Physics Conference on), 1142
Nuclear Physics at Intermediate Energies (University of Pittsburgh Conference on), 822
Nuclear Reactors : Instrumentation of (Institution of Electrical Engineers Symposium on), 411
Nuclear Research in Yugoslavia, 728
Nuclei in Coconut Milk : Dividing (Miss Mridula Dutt), 799
Nuclei of *Cyclochypeus carpenteri* Brady (Dr. Margaret W. Jepps), 1114
Nucleic Acid : Diabetogenic Effect of (Dr. Z. Brada), 524
Nucleic Acid of Tobacco Mosaic Virus . Incorporation of 8-Azaguanine into (Dr. R. E. F. Matthews), 1065
Nucleic Acid Volume : Identification of Radiosensitive Volume with (H. T. Epstein), 394
Nucleic Acids : Formation of Labile Phosphate Esters by Irradiation of, with X-Rays in Aqueous Systems (Dr. George Scholes and Dr. Joseph Weiss), 920
  Molecular Structure of—A Structure for Deoxyribose Nucleic Acid (J. D. Watson and F. H. C. Crick), 737 ; Molecular Structure of Deoxypentose Nucleic Acids (Dr. M. H. F. Wilkins, Dr. A. R. Stokes and H. R. Wilson), 738 ; Molecular Configuration in Sodium Thymonucleate (Rosalind E. Franklin and R. G. Gosling), 740
  Structure of the (Prof. Linus Pauling and Prof. Robert B. Corey), 346
Nucleic Acids in Plant Cells : Cytoplasmic Localization of (J. Chayen and K. P. Norris), 472
Nucleolar Abnormalities in Tomato : Virus-Induced (Dr. John Wilkinson), 658
Nucleophilic Substitution : Effects of Alkyl Groups in (C. W. L. Bevan, Prof. E. D. Hughes and Prof. C. K. Ingold), 301
Nucleotides (Adenine) : Formation of, from Adenine by Pigeon Liver Homogenates (Eugene Goldwasser), 126
Nucleotides (Purine) : Natural Configuration of, in Ribonucleic Acids—Chemical Hydrolysis of the Dinucleotide Phosphates (P. R. Whitfeld and Dr. Roy Markham), 1151 ; Enzymatic Splitting of Purine Internucleotide Linkages (Dr. Leon A. Heppel, Dr. Roy Markham and R. J. Hilmoe), 1152
Numerical Methods and Automatic Computing in Atomic Theory (Symposium in the University Mathematical Laboratory, Cambridge), 868
Nutrition and Metabolism of Microorganisms : The Integration of Research on the (Dr. D. D. Woods), 290

OAT Lipase and Tributyrin (F. G. Peers), 931
Ocean Basins : Seismic Study of the (Dr. E. C. Bullard), 812
Ocean Bottom Temperatures : Tertiary (C. Emiliani and G. Edwards), 887
Oceanic Island : Winter Cascading from an, and its Biological Implications (Brian P. Boden and Elizabeth M. Kampa), 426
Oceanographical Exhibition in London, 65
Oceanography : Grants in aid of Research in Marine Biology or (Challenger Society), 1054
Oceanography 1951 (National Academy of Sciences—National Research Council, Publication 208), 71
Oceanography in the United States (F. S. Russell), 71
Octopuses : Behaviour of Spider Crabs in the Presence of (H. J. Beal), 887
Œstrogen-Induced Oviduct Growth in the Folic-Acid Deficient Chick : Effect of Dietary Penicillin on Blood Composition and (W. O. Brown), 845
Œstrogens . Paper Chromatography of (P. H. Jellinek), 750
  Paper Partition Chromatography of Natural (Dr. C. Heusghem), 42
Œstrone : Non-Effect of Hyaluronidase on the Spread of (Mary E. Bromhead (Mrs. Webster) and Prof. Paul G. 'Espinasse), 46
Oil Exhibition at the City Museum, Bristol (Shell Petroleum Co., Ltd.), 677
Oil Palm Research in Nigeria, 595
Oils (Cod and other Fish-liver) : Occurrence of Vitamin E in (Dr. F. Brown), 790
Oils and Fats : Oxidation of (Oils and Fats Group of the Society of Chemical Industry Symposium on), 678 ; (Prof. C. E. H. Bawn), 1057
Oleates (Metal) Dipole Moments of (A. Gilmour, S. M. Nelson and Dr. R. C. Pink), 1075
Olefinic Components of Poison Ivy Urushiol, Cardanol and Cardol : Separation and Structural Determination of the (W. F. Symes and Prof. C. R. Dawson), 841
Olefinic and Cyano Links of Acrylonitrile in the Diels–Alder Reaction : Relative Reactivities of the (Prof. G. J. Janz and N. E. Duncan), 933
Olfactometer for observing the Behaviour of Small Animals (Prof. G. C. Varley and Roy L. Edwards), 789
Oligosaccharides : A New Method for the Paper Chromatography of (R. J. Bayly and Dr. E. J. Bourne), 385
Onion : Stomatal Behaviour in the (O. V. S. Heath), 110
'Onium' Salts : Biosynthesis and Energy Transport by Enzymic Reduction of (Dr. D. W. Woolley), 323
Ontogeny of *Brassica campestris* L. : Organization of Shoot Apex during the (S. C. Chakravarti), 223
Operational Research in Transport : Statistical Methods and (F. A. A. Menzler), 251
*Ophioglossum vulgatum* L. : Endogenous Buds in (Prof. C. W. Wardlaw), 89
*Ophryotrocha puerilis* : Genetic and Morphological Evidence for Subspecific Differences between Naples and Plymouth Populations of (Dr. Guido Bacci and Dr. Marcello La Greca), 1115
Ophthalmology and Otology : Alexander Pigott Wernher Memorial Travelling Fellowships in (Medical Research Council), 111
Opisthobranchia of Sagami Bay (Collected by H.M. the Emperor of Japan), edited by Dr. Hirotaro Hattori, *review* by Dr. J. E. Forrest, 762
Opisthobranchs : Japanese, *review* by Dr. J. E. Forrest, 762
Optical Aberrations : Newton's Work on Geometrical (Prof. A. C. S. van Heel), 305
Optical Activity in Crystal class *m* Alleged (Dr. D. Rogers), 929
Optical Crystallographic Methods : Postgraduate Summer School in (Department of Inorganic and Physical Chemistry of the University of Leeds in association with the Department of Adult Education and Extra-Mural Studies), 822
Optical Design of Double-Beam Spectrometers (E. F. Daly), 560
Optical Exaltation in Aromatic Compounds (D. W. van Krevelen, L. Blom and H. A. G. Chermin), 1075
Optical Properties of Stearic Acid Crystals : Growth and (P. M. Reynolds and Ajit Ram Verma), 486
Optical Resolution by Symmetric Agents : Natural Origin of Optically Active Substances and (Prof. John Read), 843
Optical Thickness . An Interferometer Microscope for the Accurate Measurement of (J. Dyson), 743
Optically Active Substances : Natural Origin of, and Optical Resolution by Symmetric Agents (Prof. John Read), 843
Optics and Ultrasonics (Physical Society Summer Provincial Meeting on), 867
Orbits . Interplanetary (J. G. Porter), 374
Organic Anion Binding by Denatured Bovine Serum Albumin (Dr. L. L. Uzman), 653
Organic Substances : Fractionation of Isotopes by Distillation of some (P. Baertschi, Prof. W. Kuhn and H. Kuhn), 1018
  Standard Samples of, for Physico-Chemical Measurements (D. Ambrose), 902
Orientation in Polythene Film : Crossed Amorphous and Crystalline Chain (D. R. Holmes, R. G. Miller, R. P. Palmer and C. W. Bunn), 1104
Orientation of Telotremptous Brachipoods (Prof. E. Percival), 436
Orobanchaceae : Embryology of the (B. Tiagi), 728
Orthopteroid Insects of France, *review* by David R. Ragge, 626
Orthoptéroides (Prof. Lucien Chopard), *review* by David R. Ragge, 626
Oscillating Droplets (J. B. Lewis and H. R. C. Pratt), 1155
Oscillations : Piezo-electric, of Quartz Plates at Even and Half-odd Harmonics (Dr. S. Parthasarathy, M. Pancholy and A. F. Chhapgar), 216
Osteodystrophia (Equine) : Excess of Molybdenum in Herbage as a Possible Contributory Factor in (Dr. T. Walsh and Dr. L. B. O'Moore), 1166
*Ostertagia circumcincta* : Development of, in the Abomasal Mucosa of the Sheep (R. I. Sommerville), 482
Otology : Alexander Pigott Wernher Memorial Travelling Fellowships in Ophthalmology and (Medical Research Council), 111
Ovarian Hormones : Influence of, on Uterine Infection (L. E. Rowson, G. E. Lamming and R. M. Fry), 749
Overlap Errors in the Automatic Counting and Sizing of Particles : Coincidence and (J. R. Hodkinson), 351
Overseas Development and Man-Power Problems, 405
Oviduct (Ewe's) : Mucin Secretion in the (Dr. R. Hadek), 750
Oviduct (Sheep's) : Alteration of *p*H in the (Dr. R. Hadek), 976
Oviduct Growth (Œstrogen-induced) : Effect of Dietary Penicillin on Blood Composition and, in the Folic-Acid Deficient Chick (W. O. Brown), 845
Oxalo-Acetic Acid . Metal Ion Catalysis of the Decarboxylation of (Dr. R. J. P. Williams), 304
Oxidase : Cytochrome, and the 'Pasteur Enzyme' (Prof. D. Keilin and Dr. E. F. Hartree), 413
Oxidase (Cytochrome) : Controlling Effect of Salts on the Activity of the (Prof. H. Lundegårdh), 477
Oxidation of Fatty Acids by the Isolated Liver : Role of Choline in the (Camillo Artom), 347
Oxidation of Long-Chain Paraffins : Position of Radical Attack during (Dr. J. L. Benton and M. M. Wirth), 269
Oxidation of Oils and Fats (Oils and Fats Group of the Society of Chemical Industry Symposium on), 678 ; (Prof. C. E. H. Bawn), 1057
Oxidative and Fermentative Phases : Relationship between the, during Adaptation to Galactose in *Saccharomyces cerevisiae* (Dr. A. Leonard Sheffner), 1073
Oxidimetry : Quantitative Estimation of the Total Solids in Fresh Whole Milk by (Arthur G. Leggatt), 1028
Oxygen and Carbon Dioxide Differences across the Kidney : Effect of Nervous Stimulation on the Arterio-Venous (Dr. Joseph H. Cort), 784
Oxytocic Substances : Anti-diuretic and, liberated by the Digestion of Plasmatic Proteins with Pepsin (Prof. H. Croxatto, L. Barnafi, G. Rojas, A. Reyes and A. Infante), 82

PACIFIC : American Indians in the (Thor Heyerdahl), *review* by Prof. Raymond Firth, 713
  The Fight against Filariasis in the (Sir Philip Manson-Bahr), 368
Pacific Science Congress : Eighth, 913
Paint (Marking) : Reversal of Phototaxis in Prepupae of Hymenoptera (Tenthredinidae) caused by Amyl Acetate Vapour emanating from (Dr. F. L. Waterhouse), 438

Paints and Physics: Particles, Pellicles—Pigments, (Dr. L. A. Jordan), 812
Pakistan Science Conference: The Fifth, and the Pakistan Academy of Science (Sir Harold Hartley), 771
Palaeo-Anthropology: A Classic of, review by Prof. W. E. Le Gros Clark, 361
Pan-African Congress on Prehistory, 1947: Proceedings of the (edited by L. S. B. Leakey, assisted by Sonia Cole), review by Miles Burkitt, 231
Papain, 913
Paper Pulps: Physical Properties of—Elastic Properties of Wet Mats of Paper-making Fibres (G. N. Christensen and Dr. W. W. Barkas), 165; 'Freeness' of Paper Pulps and the Forces of Capillary Water Retention (R. Hallan and Dr. W. W. Barkas), 166
Papers: Gloss of (V. G. W. Harrison and S. R. C. Poulter), 651
Paraffin Wax (Solid): Surface Free-Energy of (E. B. Greenhill and S. R. McDonald), 37
Paraffins (Long-Chain): Position of Radical Attack during Oxidation of (Dr. J. L. Benton and M. M. Wirth), 269
Paramagnetic Resonance and Covalent Bonding (J. Owen and K. W. H. Stevens), 836
Parasitic Bronchitis: Fog Fever Syndrome in (J. F. Michel), 940
Parasitic Cirripede Crustacea: Hæmoglobin and Biliverdin in (Prof. H. Munro Fox), 162
Parasitic Protozoan: A Method for the Bulk Growth of a (Dr. Joseph G. Feinberg), 1165
'Parathion' and Ultra-violet Light (Miss J. Payton), 355
Parathyroid Gland stimulating Phosphate Excretion: Hormonal Nature of Extracts of (Beryl M. A. Davies and A. H. Gordon), 1122
Parcs: Flore illustrée des Jardins et des (Dr. P. Fournier), review by Sir Edward Salisbury, 493
Parks in Great Britain: National, 558
Parliament, a Survey (Lord Campion, L. S. Amery, D. W. Brogan, J. J. Craik Henderson, Sir Arthur Salter, H. E. Dale, Ivor Thomas, F. W. Lascelles, E. C. S. Wade, Sir Cecil Carr, A. L. Goodhart, G. M. Young), 183
Parliamentary Government in Colonies: Problems of (Hansard Society), 1130
'Parsnip Canker' (A. P. Jones), 574
Parthenogenesis in a Fish: Spontaneous (Dr. H. Spurway), 437
Particle-size Analysis: The Physics of (Institute of Physics Conference on), 19
Particles: Coincidence and Overlap Errors in the Automatic Counting and Sizing of (J. R. Hodkinson), 351
    Determinations of Size of, with the Electron Microscope (E. Atherton), 350
Particles (Colloidal): Some Applications of the Separation of Large Molecules and (Prof. A. Tiselius), 290
Particles (Small): A Device for Counting, suspended in a Fluid through a Tube (Dr. P. J. Crosland-Taylor), 37
Particles (Spherical): Relationship between Relative Viscosity and Volume Concentration of Stable Suspensions of (D. R. Oliver and Prof. Stacey G. Ward), 396
Particles, Pellicles—Pigments, Paints and Physics (Dr. L. A. Jordan), 812
'Pasteur Enzyme': Cytochrome Oxidase and the (Prof. D. Keilin and Dr. E. F. Hartree), 413
Pasture: Differences in the Vitamin $B_{12}$ Content of Cow's Milk during the Last Month Indoors and the First Week at (E. E. van Koetsveld), 483
Patent Aspects: Recording of Research and its, 599
Patron's Medal of the Royal Geographical Society awarded to Count Eigil Knuth, 635
Pattern Discrimination and the Visual Cortex (D. A. Sholl and A. M. Uttley), 387
Pea Embryos in Sterile Culture (W. Kruyt), 420
Peace: Contributions of Science to (Prof. C. A. Coulson), 775
Pedler (Alexander) Lecture of the British Association for the Advancement of Science (Sir Harold Hartley), 867, 1040
Pedo-Botanical Surveys in the Belgian Congo, 154
Peek (Cuthbert) Grant of the Royal Geographical Society awarded to Duncan Carse, 636
Pellicles: Particles—Pigments, Paints and Physics (Dr. L. A. Jordan), 812
Pencil Wood: Deodar as (M. A. Rahman and Jai Kishen), 732
Penguin: The Adelie (Dr. W. J. L. Sladen), 952
Penguin (Emperor): Embryology of the (*Aptenodytes forsteri*), (T. W. Glenister), 357
Penicillin: Cephalosporin N, a New Type of (Dr. E. P. Abraham, G. G. F. Newton, K. Crawford, H. S. Burton and C. W. Hale), 343
Penicillin (Dietary): Effect of, on Blood Composition and Œstrogen-Induced Oviduct Growth in the Folic-Acid Deficient Chick (W. O. Brown), 845
Pentose: Interference of, in the Estimation of Hexose Sugars with Anthrone (R. Johanson), 176
People: Professional (Roy Lewis and Angus Maude), 93
Pepsin: Anti-diuretic and Oxytocic Substances liberated by the Digestion of Plasmatic Proteins with (Prof. H. Croxatto, L. Barnafi, G. Rojas, A. Reyes and A. Infante), 82
Peptide (Polyglutamyl): Paper Electrophoresis of (R. E. Strange and N. Harkness), 77
Perfluoroalkyl Nitroso Compounds (Dr. Joan Banus), 173
Performance: Human (Ergonomic Research Society Symposium on), 290, 960
Periodic Acid—Amino-Acid Mechanisms: Some Histochemical Observations on (Dr. John F. Lhotka), 1123
Periodicals: The Subject Index to, 1951 (Library Association), review, 587
Periodicals (German Medical and Scientific): Cost of (Springer Verlag), 403; (Dr. Wilfrid Bonser and Margaret P. Russell), 403
*Periphyllus*: The Aphid Genus (Prof. E. O. Essig and Frieda Abernathy), review by J. P. Doncaster, 765
Perissodactyls: The Ratio Molars/Premolars in (Dr. P. L. Pirlot), 972
Permeability of Cell Membranes to Glucose: Insulin and the (E. J. Ross), 125
Permeability of Insect Cuticle to Aqueous Stains and Vulnerability to Insecticides (S. Mukerji and S. N. Chatterjee), 119
Peroxide Treatment: Graphitic Acid from Aromatic Compounds by (G. A. Bottomley and J. G. Blackman), 620
ζ Persei Group of *O*- and *B*-Type Stars: Age and Evolution of the (A. Blaauw), 1005
Persistence of *Rhizoctonia solani* in Soil (G. B. Sanford), 331
Peru: The Indian Caste of, 1795–1940 (George Kubler), 686
Pests and Diseases (Plant): Assessment of (Association of Applied Biologists Symposium on), 553
Petrie (Flinders) Centenary Lecture (Prof. S. R. K. Glanville), 914
Petrie (Flinders) Collection of Egyptian Antiquities (Exhibition in the Museum of Egyptology, University College, London), 914
Petroleum Chemicals Industry in Great Britain, 679
Petroleum Industry: Careers in the (Shell Petroleum Co., Ltd., Booklets on), 1004
Petroleum Raw Materials in the U.K. Chemical Industry: Production and Utilization of (London Section of the Society of Chemical Industry and the Institute of Petroleum Symposium on), 679
Pflanzengeographischen Exkursion durch Irland 1949: Ergebnisse der 9 Internationalen—Die Pflanzenwelt Irlands (redigiert von Werner Ludi), review by Prof. P. W. Richards, 1085
Pflanzenkaryologie: Allgemeine (Prof. Dr. Georg Tischler), Hälfte 2, Kernteilung und Kernverschmelzung, Zweite Auflage, Lieferung 1 and Lieferung 2, review by Dr. C. D. Darlington, 139
Pflanzenwelt Irlands: Die (Ergebnisse der 9 Internationalen Pflanzengeographischen Exkursion durch Irland 1949, redigiert von Werner Ludi), review by Prof. P. W. Richards, 1085
pH: Effect of Changing, on Developing Trout Eggs and Larvæ (Prof. Daya Krishna), 434
pH in the Sheep's Oviduct: Alteration of (Dr. R. Hadek), 976
pH Meters: Centrifuges and (Institute of Biology Reports on), 155
Pharmacology: Practical (Prof. J. H. Burn), review, 278
Pharmacology of the Alkaloids of *Aspidosperma oblongum* A.DC. (J. N. Banerjee and J. J. Lewis), 802
Pharmacopoeia: British, 1953 (published under the direction of the General Medical Council), review by Prof. J. H. Gaddum, 990
    The Extra (Martindale), incorporating Squire's Companion, twenty-third edition, Vol. 1, review by Prof. J. H. Gaddum, 627
Phenyl Benzenesulphonates (Chlorinated): Toxicity of, to Winter Eggs of the Fruit Tree Red Spider Mite, *Metatetranychus ulmi* (Koch), (Dr. A. H. M. Kirby and R. P. Tew), 479
Philosophers: Sir Joseph Banks, K.B., P.R.S., the Autocrat of the (Dr. Hector Charles Cameron), review by Dr. Charles Singer, 449
Philosophy of the Enlightenment (Ernst Cassirer), translated by Fritz C. A. Koelln and James P. Pettegrove, review by F. I. G. Rawlins, 900
Phloem Sap: A Method of obtaining, via the Mouth-parts of Aphids (Dr. J. S. Kennedy and T. E. Mittler), 528
*Phorodon humuli* (Schrank): Transmission of Hop Mosaic by (J. Paine and J. T. Legg), 263
Phosphate Bond-Energy: The Concept of (Dr. R. J. Gillespie, Dr. G. A. Maw and C. A. Vernon), 1147
Phosphate Content of Mudbanks along the Malabar Coast (G. Seshappa), 526
Phosphate Esters: Detection of, on Paper Chromatograms (H. E. Wade and D. M. Morgan), 529
    Paper Chromatography of (E. Fletcher and Dr. F. H. Malpress), 838
Phosphate Esters (Labile): Formation of, by Irradiation of Nucleic Acids with X-Rays in Aqueous Systems (Dr. George Scholes and Dr. Joseph Weiss), 920
Phosphate Excretion: Hormonal Nature of Extracts of Parathyroid Gland stimulating (Beryl M. A. Davies and A. H. Gordon), 1122
Phosphorus-32: Standard Solutions of (Atomic Energy Research Establishment), 1141
Phosphorus Compounds: Biochemistry of, review by Dr. T. Mann, 808
Phosphorus Metabolism, a Symposium on the Role of Phosphorus in the Metabolism of Plants and Animals (sponsored by the McCollum-Pratt Institute of the Johns Hopkins University), Vol. 1 (edited by William D. McElroy and Bentley Glass), review by Dr. T. Mann, 808
Phosphorylase (Lima Bean): Effect of Added Primer on (Michinori Nakamura), 795
Photoelectric Control of the Compensator in Electrophoresis (Dr. R. L. Warren and Dr. P. A. Charlwood), 353
Photoelectric Observations of the Zodiacal Light (Prof. H. Siedentopf, A. Behr and H. Elsässer), 1066
Photoelectric Studies of the Night Sky Light (Masaaki Huruhata), 419
Photographic Science and Technique (Scientific and Technical Group of the Royal Photographic Society Conference on), 777, 1143
Photographic Sensitivity in Silver Bromide: Mechanism of (Dr. J. W. Mitchell), 115
Photography and the Amateur Astronomer (Dr. G. Merton), 244
Photo-insolubilization of Dextran (F. G. Pautard), 302
Photolysis of Acetaldehyde at High Intensity: Limiting Products in the (M. A. Khan, Prof. R. G. W. Norrish and Dr. G. Porter), 513
Photometry of Southern Elliptical Nebulæ: Surface (Dr. David S. Evans), 913
Photoperiod Sensitivity in Rice linked with Apiculus Colour: A Gene for (Dr. M. P. Chandraratna), 1162
Photoperiodic Phenomenon in Short-Day Plants: A New (Dr. P. F. Wareing), 614
Photoperiodic Response in Sheep: Additional (D. S. Hart), 133
Photosynthesis: Carbon Dioxide Concentration and Maximum Quantum Yield in (Prof. E. Steemann Nielsen), 1106
Photosynthetic Reactions: Extra-Cellular, in Entire Leaf Macerates (Dr. F. C. Gerretsen), 207
Phototaxis: Reversal of, in Prepupæ of Hymenoptera (Tenthredinidæ) caused by Amyl Acetate Vapour emanating from Marking Paint (Dr. F. L. Waterhouse), 438
Phycocyanin: Chromatography of (E. C. Wassink and H. W. J. Ragetli), 376
*Phyllopertha horticola* L.: Absorption of Water by the Egg of the Garden Chafer (Roger Laughlin), 577
Phylogeny and Morphogenesis (Prof. C. W. Wardlaw), review by Prof. W. H. Pearsall, 230
Physical Factors in relation to Biological Activity of Insecticides (Crop Protection Panel of the Agriculture Group of the Society of Chemical Industry Discussion on), 869
Physical Problems: A Trigonometric Series used in (S. K. Lakshmana Rao and B. S. Ramakrishna), 308
Physical Properties of Bile Salts: Formation of Gall Stones—(A. J. H. Rains and N. Crawford), 829

Physical Properties of Paper Pulps—Elastic Properties of Wet Mats of Paper-making Fibres (G. N. Christensen and Dr W. W. Barkas), 165, 'Freeness' of Paper Pulps and the Forces of Capillary Water Retention (R. Hallen and Dr. W. W. Barkas), 166
Physico-Chemical Measurements : Standard Samples of Organic Substances for (D Ambrose), 902
Physics  The Conceptual Situation in, and its Prospects of Development (Prof M Born), 290
  Fundamental Theoretical (International Union of Pure and Applied Physics Symposium on), 332
  International Meetings in, 332
  Meeting of Nobel Prize-winners in, 822, 1098
  Nuclear, at Intermediate Energies (University of Pittsburgh Conference on), 822
  Particles, Pellicles—Pigments, Paints and (Dr. L. A. Jordan), 812
  Solid State (Physical Society Spring Meeting on), 156, 1055
Physics (Experimental) . Exercises in (edited by N C. B. Allen and Dr. L. H. Martin), *review*, 364
Physics (Nuclear)  Experimental and Theoretical (University of Glasgow in co-operation with the International Union of Physics Conference on), 1142
Physics (Statistical) : Papers on the Basic Principles (N. S. Krylov), *review* by Dr. R. Eisenschitz, 143
Physics as a Career (Norman Clarke), *review*, 811
Physics of the Earth, *review* by Prof. B. Gutenberg, 408
Physics in the Fuel and Oil Industry : Some Applications of (Dr H. G. Nisbet), 779
Physics of the High Atmosphere (British Association for the Advancement of Science, Section A (Physics and Mathematics), Discussion on), 146
Physics of Particle-size Analysis (Institute of Physics Conference on), 19
Physics of the Solid State (University of Bristol in co-operation with the International Union of Physics Conference on), 1142
Physics in Spain  Chemistry and (Sir Eric Rideal), 915
Physics in the University of the Witwatersrand, 1139
Physics Monographs for Students, *review* by S. Weintroub, 1132
Physics and Medicine of the Upper Atmosphere (edited by Dr Clayton S. White and Brig.-General Otis S. Benson, Jr.), *review* by Dr. K. E. Spells, 51
Physiological Congress : Nineteenth International, 155
Physiological Evidence of Anastomosis of the Hepatic Artery and Hepatic Vein within the Mammalian Liver : Anatomical and (Dr W. H. Horner Andrews and Prof. B. G Maegraith), 222
Physiological Forms of *Eucalyptus citriodora* Hooker (A R Penfold and J. L. Willis), 883
Physiology : Comparative Animal (Prof David W. Bishop, Prof Frank A. Brown, Jr., Prof. Theodore L. Jahn, Prof. C. Ladd Prosser and Prof. Verner J. Wulff), *review* by Prof W. Burns, 363
Physiology of Rubber Tapping (J. P. Riches and E G. B. Gooding), 461
Phytopharmacy  Fifth Annual Symposium on, 777
*Phytophthora infestans* de Bary  Nature of 'Field Resistance' of the Potato to (K. O. Muller and J. C. Haigh), 781
Piezo-electric Oscillations of Quartz Plates at Even and Half-odd Harmonics (Dr. S. Parthasarathy, M. Pancholy and A. F. Chhapgar), 216
Pigeon Liver Homogenates : Formation of Adenine Nucleotides from Adenine by (Eugene Goldwasser), 126
Pigment and Protein  Purple, in the Threads of the Sea Anemone, *Adamsia rondeletii* (Prof. Anast. Christomanos), 886
Pigments, Paints and Physics : Particles, Pellicles— (Dr. L. A. Jordan), 812
Pile Theory . Lecture Notes on (C. A. Rennie), 110
Pine Seedlings : Transfer of Labelled Nitrogen from Glutamic Acid to, through the Mycelium of *Boletus variegatus* (Sw ) Fr. (Prof. Elias Melin and Harald Nilsson), 134
*Pinus sylvestris* : Experimental Induction of Male Cones in (Dr. P. F. Wareing), 47
*Pisum sativum* . Effects of Trichloroacetic Acid on the Extension Growth of Root and Shoot Segments of (Sen Gita and E. K. Woodford), 936
Pituitary : Relation of Adrenocorticotrophin (ACTH) to the Melanophore Expanding (B) Hormone of the (Prof. H. Waring and B Ketterer), 862
Plaine de la Ruzizi  Les associations végétales de la, en relation avec le milieu (R. Germain), 154
Planetary Influences on the Sun (M. Kopecky, P. Mayer and V. Borovičková), 956
Plankton : A Cladoceran from the, as a Possible Indicator for the Presence of the Nile Flood off the Israeli Coast (Dr. B. Komarovsky), 937
Plankton of the Benguela Current (Dr. T. J. Hart), 631
Plankton and Salinity of the Hauraki Gulf, New Zealand : Seasonal Variation in the (A. S. Fuller), 525
Plant Ashes : Microscopy of (Dr. J. W. Fairbairn), 1008
Plant Cell Walls : The Molecular Architecture of (Dr. R. D. Preston), *review* by Dr. K. Wilson, 98
Plant Cells : Cytoplasmic Localization of Nucleic Acids in (J. Chayen and K P. Norris), 472
Plant Cilia  Electron Microscopy of (I. Manton, B. Clarke, A D. Greenwood and E. A. Flint), 289
Plant Extracts : Chromatography of the Growth Substances in (Prof. T. A. Bennet-Clark and N. P Kefford), 645
Plant Fossils (Mineralized)  Staining and Plastic Embedding of small (Dr. Henning Horn af Rantzien), 516
Plant Growth Regulators (American Society of Plant Physiologists Committee to study the terminology of), 19
Plant Hormone  3-Indolylacetonitrile, an Important (J. A Bentley, S. Housley and A. S. Bickel), 505
Plant Life in the Scottish Highlands (Alexander Edward Holden), *review* by Dr George Taylor, 187
Plant Morphology and Plant Taxonomy—Angiosperms (G Erdtman), *review* by Dr. W. B. Turrill, 362
Plant Nutrition  Sand and Water Culture Methods used in the Study of (Dr. E. J Hewitt), *review* by Prof. R H. Stoughton, 232
Plant Pathology  A Pioneer of, *review*, 764
Plant Pathology (North American)  Erwin Frink Smith, a Story of (Andrew Denny Rodgers, III), *review*, 764
Plant Pests and Diseases  Assessment of (Association of Applied Biologists Symposium on), 553
*Plant Physiology* : Prof. David R. Goddard elected editor-in-chief of, 1054
Plant Physiology : Principles of (James Bonner and Arthur W. Galston), *review* by Dr. G. Bond, 6
  Text-Book of, *review* by Dr. G. Bond, 6
Plant Protection . Elements of (Dr. Louis L. Lyenson), *review* by P. E. Burt, 409
  Text-Book on, *review* by P. E Burt, 409
Plant Respiration, *review* by Dr. W. O James, 6
Plant Taxonomy : Plant Morphology and—Angiosperms (G. Erdtman), *review* by Dr W B. Turrill, 362
Plant Tissues  Occurrence of Choline Oxidase in (Dr. B. T. Cromwell and S. D. Rennie), 79
Plant and Animal Breeding (Joint Biology Committee and the Association of Agriculture Conference on), 110
Plants : Auxins and Auxin Precursors in (Dr Poul Larsen and Erik Bonde), 180
  Economics of the Protection of, *review* by Dr. L Thomas, 665
  Food Products from (Dr. A. E. Bender), 917, *erratum*, 1098
  Herbarium of Indian, at the Liverpool Public Museums (H Stansfield), 1096
  Respiration in (Prof. Walter Stiles and Prof. William Leach), *review* by Dr. W. O. James, 6
  Sand- and Water-Culture of, *review* by Prof R H Stoughton, 232
Plants (Short-Day) . A New Photoperiodic Phenomenon in (Dr. P. F. Wareing), 614
Plants (Vascular) . Taxonomy of (Prof. George H M. Lawrence), *review* by J. S. L. Gilmour, 585
Plants in Africa : Problems of Distribution of Animals and (Linnean Society of London Discussion on), 639
Plants in France . Garden Flora of Hardy, *review* by Sir Edward Salisbury, 493
Plants in Trinidad and Tobago . The Useful and Ornamental (revised fourth edition by R. O Williams and R. O Williams, Jr , original edition by W G. Freeman and R. O. Williams), *review*, 52
Plants of the Tropics  Useful, *review*, 52
Plants of the World  Economic, *review* by Prof Ronald Good, 898
Plants infected with Tobacco Mosaic Virus  Occurrence in, of a Crystallizable Antigen devoid of Ribonucleic Acid (Prof. R. Jeener and P. Lemoine), 935
Plants and Animals  Synthesis of L-Ascorbic Acid in (Dr. F. A. Isherwood, Mrs. Y T. Chen and Dr L. W Mapson), 348
Plasma (Blood)  Asparagine in (J M. Berry), 1123
Plasmatic Proteins with Pepsin  Anti-diuretic and Oxytocic Substances liberated by the Digestion of (Prof H. Croxatto, L Barnafi, G Rojas, A. Reyes and A Infante), 82
Plastic Embedding of Small Mineralized Plant Fossils : Staining and (Dr. Henning Horn af Rantzien), 516
Plastic Flow and Fracture  Studies in Large (Prof. P. W. Bridgman), *review* by Prof. A. H Cottrell, 1130
Plastic Properties of Coking Coals (Dr. J Bronowski, D. Fitzgerald, D. W. Gillings and D C. Rhys-Jones), 389
Plasticity under Pressure, *review* by Prof. A. H. Cottrell, 1130
Plastics  Educational Grants for Training in (Plastics Industry Education Fund), 200
Plastics Exhibition and Convention : British, 867
Pleistocene Geology and Prehistory of Uganda, Part 2, Prehistory (Dr. C. van Riet Lowe), *review* by M. C. Burkitt, 4
Play, Dreams and Imitation in Childhood (Prof. Jean Piaget), translated by C. Gattegno and F. M. Hodgson, *review* by Prof John Cohen, 450
Plymouth Populations of *Ophryotrocha puerilis* : Genetic and Morphological Evidence for Subspecific Differences between Naples and (Dr. Guido Bacci and Dr. Marcello La Greca), 1115
Poison Ivy Urushiol, Cardanol and Cardol  Separation and Structural Determination of the Olefinic Components of (W P. Symes and Prof. C R. Dawson), 841
Poisoning  Fluoroacetate—Comparison of Synthetic Fluorocitric Acid with the Enzymically Synthesized Fluorotricarboxylic Acid (Sir Rudolph Peters, R. W. Wakelin, D E A. Rivett and L. C Thomas), 1111
Polar Molecules in Solution : Dielectric Relaxation Time of (Nora E. Hill), 836
Polar Polymers : Frictional Electrification of (J. A Medley), 1077
Polarized Ultra-Violet Absorption of Anthracene (Dr. D P Craig and P. C. Hobbins), 566
Polarographic Congress . First International (Proceedings, Vol. 3), 677
Polishing  Electrolytic, of Lead in a Sodium Acetate—Acetic Acid Bath (Elizabeth Jones and H. R. Thirsk), 843
Political Activities of Civil Servants, 1140
Pollen  Structure of, *review* by Dr. W. B Turrill, 362
Pollution  Fluorosis and, 1097
*Polycelis felina* (= *cornuta*) and *Crenobia alpina* in the British Isles. Habitat of (Dr T. B Reynoldson), 660
*Polychaeta sedentaria*  Asexual Reproduction in *Pygospio elegans* Claparède (Erik Rasmussen), 1161
Polyglutamyl Peptide  Paper Electrophoresis of (R. E. Strange and N. Harkness), 77
Polyhaptenic Dyes  Non-specific Precipitation of Proteins by (Dr. John L. Morrison), 346
Polymer (Methyl Methacrylate)  Breakdown of, by High-Energy Radiation (Dr. A Charlesby and M Ross), 1153
Polymer Science (Seminar in University College, London), 65, 959
Polymerization of Actin : Action of Cortisone on the (J B. Cowie and Prof. R. H Thorp), 1067
Polymers (Crystalline Synthetic)  Morphology of (A. Keller), 170
Polymers (Long-chain)  Effect of High-energy Radiation on (Dr. A. Charlesby), 167
Polymers (Polar)  Frictional Electrification of (J. A. Medley), 1077
Polymorphism of *Drosophila polymorpha* . A Further Analysis of the (A Brito da Cunha), 887
Polymyxin : Absorption of, by Bacteria (Dr. A. V. Few and Dr. J. H. Schulman), 644
Polynesia : Prehistoric America and, *review* by Prof. Raymond Firth, 713
Polyols : A New Spraying Agent for Paper Chromatography of Carbohydrates and (D. J D. Hockenhull), 982

Polypeptide Chains: Compound Helical Configurations of—Structure of Proteins of the α-Keratin Type (Prof. Linus Pauling and Prof. Robert B. Corey), 59
Polypeptides (Synthetic): β-Forms of Fibrous Proteins and (Dr. C. H. Bamford, L. Brown, Dr. A. Elliott, W. E. Hanby and I. F. Trotter), 1149
Polypeptides from the Carboxyl End: Stepwise Degradation of (R. A. Boissonnas), 304
Polyploid *Saccharomyces*: X-Ray Inactivation of (W. H. Lucke and A. Sarachek), 1014
Polyploidy in Animals (Dr. C. D. Darlington), 191
Polyploidy in *Primula farinosa* L. (E. W. Davies), 659
Polystyrene: Thermal Degradation of (Paul-D. Zemany), 391
Polythene Film: Crossed Amorphous and Crystalline Chain Orientation in (Dr. R. Holmes, R. G. Miller, R. P. Palmer and C. W. Bunn), 1104
Population (Ageing): Problems of Employment in an, 623
Population Changes in Europe since 1939 (Gregory Frumkin), *review* by H. Silcock, 494
Population and Development of Food Industries in India; Food and, *review* by Sir John Russell, 1038
Populations of *Haemonchus contortus* in Sheep fed on White Clover (*Trifolium repens*) High in Lotaustralin: Inhibition of (J. H. Tetley), 311
Populations of *Ophryotrocha puerilis*: Genetic and Morphological Evidence for Subspecific Differences between Naples and Plymouth (Dr. Guido Bacci and Dr. Marcello La Greca), 1115
Pores in Synthetic Graphite: Closed (Miss E. M. Dresel and Dr. L. E. J. Roberts), 170
Porphobilinogen—Chemical Constitution (G. H. Cookson and Prof. C. Rimington), 875; X-Ray Crystallographic Determination of Molecular Weight (Mrs. Olga Kennard), 876
Post-Synaptic Discharge in a Sensory Nucleus: Repetitive (P. O. Bishop, D. Jeremy and J. G. McLeod), 844
*Potamodytes tuberosus*, Hinton: The Respiratory Bubble of the Aquatic Beetle (George A. Stride), 885
Potassium Cyanide: Ability to Smell Solutions of (R. L. Kirk and N. S. Stenhouse), 698
Potassium Effect: Inhibitory Effect of Malonate on the Respiration of Brain Tissue, with special reference to the (Y. Kimura and T. Niwa), 881
Potato: Nature of 'Field Resistance' of the, to *Phytophthora infestans* de Bary (K. O. Muller and J. C. Haigh), 781
Potato Blight Forecasting and its Mechanization (Dr. John Grainger), 1012
Potato Phosphorylase and Q-Enzyme: A Simple Method for the Preparation of Crystalline (H. Baum and Dr. G. A. Gilbert), 983
Potato Root Eelworm: Seasonal Fluctuations in the Degree of Hatching from Cysts of the (David W. Fenwick and Elizabeth Reid), 47
Potato Shoot Apex: Regeneration of the (R. Snow and Mary Snow), 224; (I. M. Sussex), 224
Potato-Tubers: Effect of Leaf Roll Virus Infection on the Soluble Nitrogen Composition of (R. M. Allison), 573
Potato Tubers in India: Occurrence of *Verticillium* in (Prof. K. S. Bhargava and Hari Kishore), 800
Potato Virus Y: Infectivity of Aphids after Several Hours on Tobacco infected with (Dr. R. H. E. Bradley), 755
Potential Barrier: Height of the, in Barrier Layer Cells (M. S. Ridout), 219, *erratum*, 246
Powder Diffraction Data (X-Ray): A.S.T.M. Index of (American Society for Testing Materials), 155
Prawn, *Leander serratus*: Neurosecretory Pathways in the (Dr. Francis G. W. Knowles), 131
Precipitation of Proteins by Polyhaptenic Dyes: Non-specific (Dr. John L. Morrison), 346
Precision Method for the Measurement of Ultrasonic Velocities in Liquids: A New (Dr. B. Ramachandra Rao and K. Subba Rao), 1077
Precursors of Adrenaline: Detection of some, by Paper Chromatography (D. M. Shepherd and Dr. G. B. West), 1160
Predacious Mosquito Larvae (James G. Halcrow), 1167
Predator on *Creontiades pallidus*, Ramb. (Alan Goodman), 886
Prehistoric America and Polynesia, *review* by Prof. Raymond Firth, 713
Prehistoric Congress: Fourth Far Eastern, 913
Prehistory: Proceedings of the Pan-African Congress on, 1947 (edited by L. S. B. Leakey, assisted by Sonia Cole), *review* by Miles Burkitt, 231
Prehistory in Africa, *review* by Miles Burkitt, 231
Prehistory of Uganda: The Pleistocene Geology and, Part 2, Prehistory (Dr. C. van Riet Lowe), *review* by M. C. Burkitt, 4
Preparation of Crystalline Potato Phosphorylase and Q-Enzyme: A Simple Method for the (H. Baum and Dr. G. A. Gilbert), 983
Prepupae of Hymenoptera (Tenthredinidae): Reversal of Phototaxis in, caused by Amyl Acetate Vapour emanating from Marking Paint (Dr. F. L. Waterhouse), 438
Prepupal Moult in the Blowfly (*Calliphora erythrocephala*), (Dr. P. Tate), 341
Present Question Conference on Conflicts of Loyalties, 665
Present Question Conference on Springs of Action, 867
Preservation of the Lake District, 71
Preservation of Normal Tissues for Transplantation (Ciba Foundation Symposium on), 1047
Press Guide to British Chemicals and their Manufacturers (Association of British Chemical Manufacturers), 821
Pressure: Plasticity under, *review* by Prof. A. H. Cottrell, 1130
Pressure of Radiation (Prof. R. V. Jones), 1089
Pressures (High): Experimenting at (Prof. D. M. Newitt and K. E. Bett), 668
Prestressed Concrete (Prof. Kurt Billig), *review* by W. Merchant, 854
Preventive Action of Tetanus Toxoid: Rapid Specific (M. Raynaud and E. A. Wright), 797
Priestley Medal of the American Chemical Society awarded to Sir Robert Robinson, 777
Primates: Studies on, 18
Primer: Effect of Added, on Lima Bean Phosphorylase (Michinori Nakamura), 795
*Primula farinosa* L.: Polyploidy in (E. W. Davies), 659
Principle in Taxonomy: A Possible New, and its Evolutionary Implications (R. A. Crowson), 883
'Private' Blood Factors, Homozygotes, and the Search for New Blood Groups (Dr. Bruce Chown and Marion Lewis), 700
Probability: Proceedings of the Second Berkeley Symposium on Mathematical Statistics and (edited by Jerzy Neyman), *review* by Prof. M. G. Kendall, 410, 463
*Procolobus verus*: The African Olive Colobus Monkey (W. C. Osman Hill), 18
Production in the Buffalo: Longevity and (Dr. K. A. Alim), 755
Productivity of the Sea: The Biology and (Institute of Biology Symposium on), 1005
Professional People (Roy Lewis and Angus Maude), 93
Professional Standards in the Welfare State, 93
Properties of Matter: Awkward, *review* by D. R. Wilkie, 53
Proportions: A Harmony of, *review* by F. I. G. Rawlins, 1037
Protection from the Effects of Radiation (Industrial Radiology Group of the Institute of Physics and the Hospital Physicists Association Discussion on), 20, 378
Protection of Plants: Economics of the, *review* by Dr. I. Thomas, 665
Protein: Purple Pigment and, in the Threads of the Sea Anemone, *Adamsia rondeletii* (Prof. Anast. Christomanos), 886
Protein Biosynthesis: The Template Theory and the Role of Transpeptidation in (Dr. C. E. Dalgliesh), 1027
Protein Chemistry: Advances in (edited by M. L. Anson, Kenneth Bailey and John T. Edsall), Vol. 7, *review*, 276
Protein Monolayers: Formation of Fibres from (Dr. J. Gordin Kaplan and M. J. Fraser), 559
Protein Synthesis: Possible Role of Proteolytic Enzymes in (Robert B. Loftfield, John W. Grover and Mary L. Stephenson), 1024
Proteins: Amino Acids and (compiled and edited by Prof. David M. Greenberg), *review* by Dr. C. H. Bamford, 765
  Biosynthesis of (Dr. P. N. Campbell and Dr. T. S. Work), 997
  Non-specific Precipitation of, by Polyhaptenic Dyes (Dr. John L. Morrison), 346
  Serum, in Africans (M. W. Stanier), 880
Proteins (Fibrous): β-Forms of, and Synthetic Polypeptides (Dr. C. H. Bamford, L. Brown, Dr. A. Elliott, W. E. Hanby and I. F. Trotter), 1149
Proteins (Neutral): Separation of, on Ion-Exchange Resins (N. K. Boardman and Dr. S. M. Partridge), 208
Proteins (Plasmatic): Anti-diuretic and Oxytocic Substances liberated by the Digestion of, with Pepsin (Prof. H. Croxatto, L. Barnafi, G. Rojas, A. Reyes and A. Infante), 82
Proteins of the α-Keratin Type: Compound Helical Configurations of Polypeptide Chains—Structure of (Prof. Linus Pauling and Prof. Robert B. Corey), 59
Proteolytic Enzymes in Protein Synthesis: Possible Role of (Robert B. Loftfield, John W. Grover and Mary L. Stephenson), 1024
Proton Linear Accelerator: A New Focusing Principle applied to the (J. S. Bell), 167
Protons in Atomic Nuclei: Difference between the Density Distribution of Neutrons and (Prof. P. Gombás), 979, *erratum*, 1054
Protopine (Alkaloid): Origin of the Methylenedioxy Groups of the (M. Sribney and Prof. S. Kirkwood), 931
Protoplasmic Movement: Mechanism of (Prof. William Seifriz), 1136
Protoporphyrin in the Integument of *Asterias rubens* (G. Y. Kennedy and Dr. H. G. Vevers), 81
Prototrophs: Competitive Suppression of (Dr. Francis J. Ryan), 400
Protozoa and Metal-binding Substances: Carbohydrate Metabolism in (J. F. Ryley), 747
Protozoan (Parasitic): A Method for the Bulk Growth of a (Dr. Joseph G. Feinberg), 1165
Psychiatrist's Credo: A, *review* by Dr. Clifford Allen, 232
Psychiatry: Social (Dr. Maxwell Jones and A. Baker, Dr. Thomas Freeman, Julius Merry, B. A. Pomryn, Dr. Joseph Sandler, Joy Tuxford), *review* by Dr. Clifford Allen, 667
Psychic Oddities (Hereward Carrington), *review* by Dr. E. J. Dingwall, 320
Psychic Reminiscences, *review* by Dr. E. J. Dingwall, 320
Psychological Effects: Chemistry and Inter-Relationships of Endocrine Systems and their (Society for Visiting Scientists Discussion on), 509
Psychological Problems of Ageing: Some Social and (British Association for the Advancement of Science, Section J (Psychology), Discussion on), 422
Psychology in the United States: Study of (American Psychological Association), 110
Psychopathology of Genius, *review* by Dr. E. J. Dingwall, 586
Psychosurgical Problems (Columbia Greystone Associates), Second Group, (edited by Dr. Fred A. Mettler), *review* by Dr. H. J. Eysenck, 231
Psychosurgical Studies at the Greystone Hospital, *review* by Dr. H. J. Eysenck, 231
Publications: Technical, 1947 (Members of the Standard Oil Co. (New Jersey) and affiliated organizations), *review*, 278
*Puccinia polysora* Underw. in East Africa: Occurrence of (R. M. Nattrass), 527
Pump (Electronic): Methods of obtaining High Vacuum by Ionization—Construction of an (Dr. Helmut Schwarz), 600
Purification and Cellulolytic Activity of *Cellvibrio* (J. P. Voets and J. K. Van Hove), 1073
Purine Nucleotides in Ribonucleic Acids: Natural Configuration of the—Chemical Hydrolysis of the Dinucleotide Phosphates (P. R. Whitfeld and Dr. Roy Markham), 1151; Enzymatic Splitting of Purine Internucleotide Linkages (Dr. Leon A. Heppel, Dr. Roy Markham and R. J. Hilmoe), 1152
Purple Pigment and Protein in the Threads of the Sea Anemone, *Adamsia rondeletii* (Prof. Anast. Christomanos), 886
*Pygospio elegans* Claparède (*Polychaeta sedentaria*): Asexual Reproduction in (Erik Rasmussen), 1161

QUANTITATIVE Estimation of the Total Solids in Fresh Whole Milk by Oxidimetry (Arthur G. Leggatt), 1028
Quantum Hit Theory: Application of the, to Tumours induced by Ultraviolet Radiation (Simon Iversen and Dr. Niels Arley), 257
Quantum Theory (Dr. David Bohm), *review* by Dr. K. J. Le Couteur, 276
Quantum Yield in Photosynthesis: Carbon Dioxide Concentration and Maximum (Prof. E. Steemann Nielsen), 1106
Quartz Plates at Even and Half-odd Harmonics: Piezo-electric Oscillations of (Dr. S. Parthasarathy, M. Panch[illegible] and A. F. Chhapgar), 216

Quaternary Compounds possessing Lasting Local Anaesthetic Action : Synthesis of (Dr K. Nádor, F. Herr, Gy. Pataky and J Borsy), 788
Quaternary Derivatives of Benzoyltropine and Benzoyl-ψ-tropine with Anticholinergic and Local Anaesthetic Properties (Dr. László Gyermek), 788
Quinhydrone Type : Molecular Compounds of the (Dr. S. C. Wallwork and T. T. Harding), 40
Quinquennial Grants : The Principle of, 317
Quiroga, a Mexican Municipio (Donald D. Brand), 686
Quo Vadis A Botanist's—Integration or Specialization, *review* by Prof. W. H. Pearsall, 230

RABBIT A Sphincter in the Umbilical Ring of the (I Maureen Young), 703
Rabbit Problem in Gotland Island (G. Notini and S Forselius), 374
Racemic Mixtures Resolution of, by Symmetrical Agents (Ricardo Carvalho Ferreira), 39
Racial Differences The Significance of (Dr. G. M. Morant), 292
Radial-Velocity Determinations of Stars : Wave-lengths for (K. O Wright), 637
Radiation : Pressure of (Prof. R. V. Jones), 1089
  Protection from the Effects of (Industrial Radiology Group of the Institute of Physics and the Hospital Physicists Association Discussion on), 20, 378
Radiation (High-Energy) : Breakdown of Methyl Methacrylate Polymer by (Dr. A. Charlesby and M. Ross), 1153
  Effect of, on Long-chain Polymers (Dr. A. Charlesby), 167
Radiation (Infra-red) New Spectrophotometer for Visible and Near (Unicam Instruments (Cambridge), Ltd.), 200
Radiation (Ionizing) : Effect of Lymphocytes on (Prof R. J. V Pulvertaft, C. W. Wilson and Howard Jayne), 1157
Radiation (Ultra-violet) Application of the Quantum Hit Theory to Tumours induced by (Simon Iversen and Dr. Niels Arley), 257
$\gamma$ Radiation Reduction of Ferric Ion in Aqueous Solution by (C. B. Amphlett), 690
Radiation induced by Alpha-Particles in Thin Films (Amos Norman, M. A. Greenfield and Paul M. Kratz), 487
Radical Attack during Oxidation of Long-Chain Paraffins : Position of (Dr. J. L. Benton and M. M Wirth), 269
Radio . Awards for Technical Articles on (Radio Industry Council), 200
Radio and the Coronation, 1050
Radio Astronomy . A High-Resolution Aerial for (W. N. Christiansen), 831
Radio Echoes observed during Aurorae and Terrestrial Magnetic Storms using 35 and 74 Mc./s. Waves Simultaneously (Prof. L Harang and B. Landmark), 1017
Radio Emission from Sunspots A Method of Analysis of the Directivity of Solar (T. Takakura), 445
Radio Research in the British Commonwealth, 683
Radio Waves from Frozen Terrains : Reflexion Coefficient of (J. R. Garlick), 259
56-Mc./s. Radio Waves from the Lower Atmosphere : Scattering of (P. A. Forsyth, Prof. B. W. Currie and F. E. Vawter), 352
Radioactive Isotopes : Standards of (National Physical Laboratory), 676
Radioactive Materials : Techniques of using and handling (Further course of Instruction at the Harwell Isotope School), 548
Radioactive Starch, Glucose and Fructose from Tobacco Leaves (H. K. Porter and R. V Martin), 505
Radioactive and Toxic Substances . Handling of (Atomic Energy Research Establishment Symposium on), 294
Radioactivity Chemistry's Debt to, *review* by Prof. F. A. Paneth, 625
Radioactivity Applied to Chemistry (edited by Arthur C. Wahl and Norman A. Bonner), *review* by Prof. F. A. Paneth, 625
Radioiodide from Urine : A Rapid Method for the Extraction of (D. G. Arnott and J. Wells-Cole), 269
Radio-Isotope Applications : Instruments and Accessories for (edited by Dr Denis Taylor and A. G. Peacock), second edition, 460
Radioisotope Methodology Course on (Organized by the Faculty of Medicine of the University of São Paulo), 289
Radioisotope Techniques—Proceedings of the Isotope Techniques Conference, Oxford 1951, sponsored by the Atomic Energy Research Establishment, Vol. 2, Industrial and Allied Research Applications, 1007
Radioisotopes Production and Uses of (Dr Henry Seligman), 588
Radiological Decontamination . Ion-exchanging Surfaces in (E. W. Jackson and Miss L. Garrard), 442
Radiosensitive Volume : Identification of, with Nucleic Acid Volume (H. T. Epstein), 394
Radium in Deep-Sea Sediments : Vertical Distribution of (Dr. Viktor St. Kroll), 742
Radium E Beta-Spectrum of (J. Pniewski and M. Danysz), 694
Rainfall : Reports on Experiments at Kongwa on Artificial Control of (D A. Davies, D. Hepburn and H. Sansom), 829
Raman Effect : Twenty-fifth Anniversary of the Discovery of the (Meeting of the Indian Association for the Cultivation of Science to celebrate the), 504
Ramsay Memorial Fellowships for Chemical Research, 421
*Rana temporaria* : Action of Insulin on the Frog (C. L. Smith), 311
Randomly Stacked Layers in Clay Minerals (Dr. Douglas M. C. MacEwan), 616
Range Management, Principles and Practices (Prof. Arthur W. Sampson), *review*, 97
Raoult's Law—a Pseudo-Ideal System (A. Blackburn and Dr. J. J Kipling), 174
Rape-oil Fatty Acids Urea Complexes of (J. H. Skellon and C. G. Taylor), 266
Rat : Effect of Nitrogen Mustard on an Inherited Character in the (P. Armitage), 1117
  Nerve Fibres in the Adrenal Cortex of the (J. D. Lever), 882
Rat Diaphragm : Effect of Acetoacetate on Glycogen Synthesis and Glucose Utilization in the Isolated (A. Chari and E. Wertheimer), 44
*Rational Mechanics and Analysis, Journal of* (New quarterly published by the Graduate Institute for Applied Mathematics, Indiana University), 866
Rations of Milking Cows : Effect of Copper Supplement to the (Dr. George Dunlop), 356
Rats : Influence of Trypan Blue on the Number of Circulating Eosinophils in (Dr Ines Wesley), 266
Rats (Adult) Percentage of Binucleate Cells in the Livers of (Marion F. Harrison), 611
Rats (New-born) Lipoids and Cholesterol in (Zdenek Dvořák), 432
Raw Materials of Life (Dr. D P. Riley and Dr. U. W. Arndt), 144
Reaction : A Disulphide Interchange (Dr. F Sanger), 1025
  A New Transamination (L. Fowden and J Done), 1068
Reaction (Jaffé) . Determination of Creatinine by the (Dr. G. R. Hervey), 1125
Reaction in Ethanol Solution from −80° C. to +20° C : Kinetics of (Dr. E. F. Caldin, G. Long and F. W. Trowse), 1124
Reaction Kinetics of the Cytochrome System (Prof H Lundegårdh), 521
Reactions : Extra-Cellular Photosynthetic, in Entire Leaf Macerates (Dr F. C Gerretsen), 207
Reactivities of the Olefinic and Cyano Links of Acrylonitrile in the Diels–Alder Reaction Relative (Prof. G J. Janz and N E. Duncan), 933
Reactors (Nuclear) : Instrumentation of (Institution of Electrical Engineers Symposium on), 411
Red Alga Studies of a (Dr. K. M. Drew), 331
Red Blood Cell Studies : Isotope Curves in (D. S. Amatuzio and Robert L. Evans), 797
Red-Cell Survival and Ashby Curves (Robert L. Evans and D. S Amatuzio), 798
Red Sea : *Murex* from the (Sister Monica Taylor), 756
  Under the (Hans Hass), translated from the German by James Cleugh, *review* by Dr Alan J Brook, 811
Red Spider Mite, *Metatetranychus ulmi* (Koch) : Toxicity of Chlorinated Phenyl Benzenesulphonates to Winter Eggs of the Fruit Tree (Dr. A. H. M. Kirby and R. P. Tew), 479
Reduction of Ferric Ion in Aqueous Solution by $\gamma$ Radiation (C B. Amphlett), 690
Reflecting Films : Multi-layer Dielectric, at Wave-lengths between 4000 and 4600 A. (J. Ring and Dr. W. L Wilcock), 643
Reflexion Coefficient of Radio Waves from Frozen Terrains (J. K. Garlick), 259
Reflection Fringes . Transmission-like, in Birefringent Crystals (Ajit Ram Verma), 396
Refractometry of Living Cells (Dr R. Barer, K. F. A Ross and S. Tkaczyk), 720
Regeneration of the Potato Shoot Apex (R Snow and Mary Snow), 224 ; (I. M. Sussex), 224
Rehabilitation and Training Centre : A Model, 866
Rehydration : Hardening of Kaolin on (R. D. Hill), 567
Relationship Probable, between the *Rhodometopa* Group of Cercariae and the Trematode Genus *Renicola* Cohn (C. A Wright), 1072
Relationship between the Oxidative and Fermentative Phases during Adaptation to Galactose in *Saccharomyces cerevisiae* (Dr A Leonard Sheffner), 1073
Relative Viscosity and Volume Concentration of Stable Suspensions of Spherical Particles Relationship between (D. R. Oliver and Prof. Stacey G. Ward), 396
Relativity Text-Book on, *review* by Prof. J. L. Synge, 140
  The Theory of (Prof C. Møller), *review* by Prof. J L. Synge, 140
Relativity (General) . 'Newtonian' Time in (Prof. P C. Vaidya), 260
Relativity and the Creator Kinematic, *review* by Sir Harold Spencer Jones, 584
Relaxation Methods Easter Vacation School in (Imperial College of Science and Technology), 333
Relaxation Time of Polar Molecules in Solution : Dielectric (Nora E. Hill), 836
Religion : The Place of Dancing in, *review* by M. C. Burkitt, 667
Religious Dances in the Christian Church and in Popular Medicine (Prof. E. Louis Backman), translated by E. Classen, *review* by M C Burkitt, 667
*Renicola* Cohn : Probable Relationship between the *Rhodometopa* Group of Cercariae and the Trematode Genus (C. A. Wright), 1072
Repellents to simplify Insecticide Field Trials . Use of (K. S. McKinlay), 658
Repetitive Post-Synaptic Discharge in a Sensory Nucleus (P. O. Bishop, D. Jeremy and J G. McLeod), 844
Reproduction in *Pygospio elegans* Claparède (*Polychaeta sedentaria*) : Asexual (Erik Rasmussen), 1161
Reproductive System of Garter Snakes Seasonal Variation in the (Wade Fox), 957
Research Atomic Energy, in Britain, 820
  Atomic Energy, at Harwell, 205
  The Basis of, 1033
  Colonial, 1951–1952 (Colonial Office), 112
  Fisheries, in British Colonies (F. S Russell), 159
  Fundamental and Applied, in relation to the University (Dean Ernest R. Hilgard), 289
  Government Scientific, in Great Britain, 709
  Marine Biology, in Great Britain (Dr. N B Eales), 823
  Nuclear, in Yugoslavia, 728
  Oil Palm, in Nigeria, 595
  Radio, in the British Commonwealth, 683
  Records of (J. G. Jackson), 599
  Scientific, in British Universities during 1951–52, 109
  Scientific, and the Ministry of Supply, 329
  Sociological, in Africa South of the Sahara (Meeting of the Scientific Council for Africa South of the Sahara to consider), 246
Research (Agricultural) : Careers in (Agricultural Research Council), 330
Research (Anti-Fouling) Gregariousness in Barnacles in relation to the Fouling of Ships and to (Dr. E W. Knight-Jones and Dr D. J Crisp), 1109
Research (Biological) Aid for, in Europe (New York Zoological Society), 638
Research (Chemical) : Ramsay Memorial Fellowships for, 421
Research (Clinical) : Fellowships in (Medical Research Council), 20
Research (Fish) Humber Laboratory for, 159
Research (Forest) Statistical Methods in (J. N. R. Jeffers), 511
Research (Medical) : Beit Memorial Fellowships for (Awards), 1097
Research (Operational) : Statistical Methods and, in Transport (F. A. A. Menzler), 251

Research (Scientific) : An Introduction to (Prof. E. Bright Wilson, Jr.), *review* by Dr. S. Whitehead, 451
  The Practice of, *review* by Dr. S. Whitehead, 451
  State Support for, 895
Research (University) : General Principles of, 289
Research in British Colonial Territories, 112, 157
Research in Coal Mining, 676
Research on Diseases of the Blood : Grants, Scholarships and Fellowships for (Lady Tata Memorial Fund), 246
Research in Electron Optics Recent (Physical Society Discussion on), 596
Research on Leukaemia and allied Diseases (Lady Tata Memorial Trust Awards), 1098
Research in Marine or Freshwater Science : Grants for (Development Commission), 729
Research in Marine Biology or Oceanography : Grants in aid of (Challenger Society), 1054
Research in Nationalized Industries, 447
Research on the Nutrition and Metabolism of Microorganisms : The Integration of (Dr. D. D. Woods), 290
Research and its Patent Aspects : Recording of, 599
Research in Rural Electrification—Work at the Electrical Research Association, 1103
Research in the Social Sciences : Register of, in Progress and in Plan, No. 9, 1951–52 (edited by Feodora Stone), 468
Research Activities of the Radiophysics Laboratory (Commonwealth Scientific and Industrial Research Organization), 1053
Research Awards (National Science Foundation), 506
Research Expenditure in the United States, 727
Research Fellowship : Gerontological (Nuffield Foundation), 462
Research Fellowships and Scholarships : Senior (Lady Tata Memorial Trust Awards), 1098
Research Fellowships in the field of Electronics (Massachusetts Institute of Technology), 377
Research Fellowships at Government Scientific Establishments, 200
Research Fellowships in Tuberculosis : Dorothy Temple Cross (Medical Research Council), 111
Research Studentship in Geophysics (Royal Dutch-Shell Group), 729
Research Studentships (Trinity College, Cambridge), 377
  MacKinnon (Royal Society Awards), 66
Research Studentships in Zoology (Zoological Society of London), 638
Research Worker : Government Information and the (edited by Ronald Staveley), *review* by R. B., 188
Research and Development by the Ministry of Supply : Increased Expenditure for, 288
Research and Industry · Scientific Instruments for—Physical Society's Exhibition, 1953 (Dr. A. B. Wood), 812
  Scientific Instruments in, 1081
Research and Organization · Forestry, 511
Researches on High-Frequency Phenomena and Electrical Direct Heating, 957
Resins (Ion-Exchange) : Separation of Neutral Proteins on (N. K. Boardman and Dr. S. M. Partridge), 208
Resins and Solutions containing Sugars : An Action of Strongly Basic Anion-Exchange (Dr. A. C. Hulme), 610
Resolution of Racemic Mixtures by Symmetrical Agents (Ricardo Carvalho Ferreira), 39
Resonance : Paramagnetic, and Covalent Bonding (J. Owen and K. W. H. Stevens), 836
Resonance Absorption in Liquid Methyl Palmitate and Methyl Stearate in the Microwave Region (T. J. Buchanan), 695
Resonance Radiation from Hydrogen Flames containing Alkali Metals (C. G James and Dr. T. M. Sugden), 428
Resources (World) : Conservation of, 1
Resources for Freedom (A Report to the President by the President's Materials Policy Commission), Vol. 1, Foundations for Growth and Security, Vol. 4, The Promise of Technology, 1
Respiration of Brain Tissue . Inhibitory Effect of Malonate on the, with special reference to the Potassium Effect (Y. Kimura and T. Niwa), 881
Respiration in Plants (Prof. Walter Stiles and Prof. William Leach), *review* by Dr. W. O. James, 6
Respiratory Bubble of the Aquatic Beetle, *Potamodytes tuberosus*, Hinton (George A. Stride), 885
'Response Balance' for Studying Insect Behaviour : A Simple (Dr. H. Hurst), 1120
Reticulin and Collagen (S. G. Tomlin), 302
Reversal of Phototaxis in Prepupae of Hymenoptera (Tenthredinidae) caused by Amyl Acetate Vapour emanating from Marking Paint (Dr. F. L. Waterhouse), 438
Reversible Dissociation of Insulin (Eugène Fredericq), 570
Rheology : Second International Congress on, 677
*Rhizoctonia solani* in Soil : Persistence of (G. B. Sanford), 331
*Rhodometopa* Group of Cercariae and the Trematode Genus *Renicola* Cohn : Probable Relationship between the (C. A. Wright), 1072
Rhodopsin and Indicator Yellow (Dr. F. D. Collins), 469
Ribonuclease (Liver) : Effect of Sulphydryl Reactants on (Jay S. Roth), 127
Ribonucleic Acid : Occurrence in Plants Infected with Tobacco Mosaic Virus of a Crystallizable Antigen devoid of (Prof. R. Jeener and P. Lemoine), 935
Ribonucleic Acids : Natural Configuration of the Purine Nucleotides in—Chemical Hydrolysis of the Dinucleoside Phosphates (P. R. Whitfeld and Dr. Roy Markham), 1151 ; Enzymatic Splitting of Purine Internucleotide Linkages (Dr. Leon A. Heppel, Dr. Roy Markham and R. J. Hilmoe), 1152
Ribose and the Maillard Reaction in Fish Muscle (Dr. H. L. A. Tarr), 344
Ricci Calculus (Prof. H. S. Ruse), 61
Rice : A Gene for Photoperiod Sensitivity in, linked with Apiculus Colour (Dr. M. F. Chandraratna), 1162
Rinderpest Viruses (Caprinized and Lapinized) : Recovery of, from Condensed Water Vapour removed during Desiccation (A. L. C. Thorne), 609
Riss-Wurm Interglacial Deposit at Ipswich (Harold E. P. Spencer), 578
River Water : Adsorption of DDT on Suspended Solids in, and its Role in Black-fly Control (F. J. H. Fredeen, A. P. Arnason and B. Berck), 700
Robertson (W. H. A.) Medal for 1952 of the Institute of Metals awarded to J. P. Wright, 377
Rock Engravings in the Kilimanjaro Area (H. A. Fosbrooke, sen., and Petro I. Marealle), 957
Rockefeller Travelling Fellowships in Medicine (Medical Research Council), 111
Rocket Observations of the Upper Atmosphere : Synoptic (Dr. S. F Singer), 1108
Rockets (Society for Visiting Scientists Discussion on), 1006
Rocks : Magnetic Properties of (Royal Astronomical Society and the Geological Society Geophysical Discussion on), 500
Rodent Control Exhibition (Royal Sanitary Institute, in collaboration with the Infestation Control Division of the Ministry of Agriculture and Fisheries), 867
Root Apices : Enzymic Systems in (E. Robinson and R. Brown), 636
Root Eelworms (*Heterodera* spp.) : Hatching Responses in (F. G. W. Jones and R. D. Winslow), 478
Root and Shoot Segments of *Pisum sativum* : Effects of Trichloroacetic Acid on the Extension Growth of (Sen Gita and E. K. Woodford), 936
Rooting of Cut Shoots of Cotton in Culture Filtrate of *Fusarium vasinfectum* (R. Kalyanasundaram and K. Lakshminarayanan), 1120
Roots : Mechanism of Ion Absorption by (Emanuel Epstein), 83
Roots (Mycorrhizal Strawberry) : Fructifications associated with (Barbara Mosse), 974
Rubber Tapping : Physiology of (J. P. Riches and E. G. B. Gooding), 461
Rumania · Health Education in (Dr. S. Leff), 728
Rumen Bacterial Fractions : Encapsulation in (P. N. Hobson and Margaret J. MacPherson), 129
Rumford Bicentenary Celebrations in the United States (American Academy of Arts and Sciences), 376
Rumford Bicentennial Symposia and Awards (Prof. F. E. Simon), 915
Rumford Medals of the American Academy of Arts and Sciences awarded to Prof. E. Fermi, Prof. W. E. Lamb, Jun., and Prof. L. Onsager, 376, 916
Rural Life in Aberdeen · Depopulation and (Bertram Hutchinson), 643
Rural Life in Scotland : Depopulation and, 643
Rural Life in the Solway Counties : Depopulation and (Bertram Hutchinson), 643
Rural Life in the Tweed Valley : Depopulation and (Bertram Hutchinson), 643
Russell Effects with Single Crystals of Zinc . Kramer and (L. Grunberg and Dr. K. H. R. Wright), 890, *erratum*, 914
Russia's Lomonosov (Boris N. Menshutkin), translated from the Russian by Jeannette Eyre Thal and Edward J. Webster, *review* by Prof. J R. Partington, 138
Russian, Serbian and Bulgarian for Bibliographical Purposes : The Transliteration of (Royal Society), 548
Ruzizi : Les associations végétales de la Plaine de la, en relation avec le milieu (R. Germain), 154
Rye (Winter) · Accelerating Effect of an Extract of Vernalized Embryos of, on Flower Initiation in Unvernalized Embryos (O. N. Purvis and Prof. F. G. Gregory), 687

SACCHAROMYCES : Mitochondrial Distribution in (Dr. Balaji D. Mundkur), 793
*Saccharomyces* (Polyploid) · X-Ray Inactivation of (W. H. Lucke and A. Sarachek), 1014
*Saccharomyces cerevisiae* : Relationship between the Oxidative and Fermentative Phases during Adaptation to Galactose in (Dr. A. Leonard Sheffner), 1073
Safety (Intrinsic) : A Theoretical Approach to the Problem of determining the Relationship between the Constants of Circuits and their (Dr. B. Roston), 397
Sagami Bay : Opisthobranchia of (Collected by H.M. the Emperor of Japan), edited by Dr. Hirotaro Hattori, *review* by Dr. J. E. Forrest, 762
Sahara : Sociological Research in Africa South of the (Meeting of the Scientific Council for Africa South of the Sahara to consider), 246
Salicylates : Hyaluronidase and (Dr. T. D Day), 268
Salinity of the Hauraki Gulf, New Zealand : Seasonal Variation in the Plankton and (A S. Fuller), 525
Salivary Chromosome Method : Extension of the, to *Anopheles claviger*, *quadrimaculatus* and *aquasalis* (Dr. G. Frizzi), 1072
Salt Fractionation of Enzyme Preparations . Column Procedures for the (Sigmund Schwimmer), 442
Salts : Controlling Effect of, on the Activity of the Cytochrome Oxidase (Prof. H. Lundegårdh), 477
Salts (Inorganic) : Specific Volume of Cellulose in Aqueous Solutions of (Dr. S. M. Neale and G. R. Williamson), 842
Sand and Water Culture Methods used in the Study of Plant Nutrition (Dr. E. J. Hewitt), *review* by Prof. R. H. Stoughton, 232
Sap (Phloem) : A Method of obtaining, via the Mouth-parts of Aphids (Dr. J. S. Kennedy and T. E. Mittler), 528
Saprophytic *Cladosporium* in Britain (Merfyn Richards), 615
Sardine Fishery of California, 872
Scatter Fringes of Equal Thickness (J. M. Burch), 889
Scholars : Gods, Graves and ; the Story of Archaeology (C. W. Ceram), translated from the German by E. B. Garside, *review* by M. C. Burkitt, 765
Scholarship (Institution of British Agricultural Engineers), 333
Scholarship in Textile Technology : Cotton Industry War Memorial Trust (Textile Institute), 506
Scholarships (Ministry of Agriculture and Fisheries), 201
  Postgraduate (Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland), 596
  Senior Research Fellowships and (Lady Tata Memorial Trust Awards), 1098
Scholarships in Medical Science : French Government Exchange (Medical Research Council), 111
Scholarships for work in the Department of Nuclear Physics (Australian National University), 156
Scholarships in Science and Engineering (National Research Council of Canada), 66
Scholarships and Bursaries : Fellowships, in Dentistry, Biology and the Social Sciences (Nuffield Foundation), 246
Scholarships and Fellowships : Grants for research on Diseases of the Blood (Lady Tata Memorial Fund), 246

- School: From Primary, to Secondary School (Mathematical Association Discussion on), 779

  Persistence of *Rhizoctonia solani* in (G. B. Sanford), 331
'Soil' · The Term (Robert F. Legget), 574
Soil Arthropods : Effects of DDT and BHC on (J. G. Sheals), 978
Soil Conditioners : 'Krilium' and Synthetic (Prof. J. H. Quastel), 7
Soil Fertility and Crop Production—Meeting in Dublin (T. Walsh), 67
Soil Fumigant (Dichloropropene-Dichloropropane) : Tainting of Tobacco by a (R. McChlery), 578
Soil Mechanics and Foundation Engineering : Third International Conference on, 245
Soils . Use of the Warburg Respirometer to study Microbial Activity in (F. E. Chase and Dr. P. H. H. Gray), 481
Soils (Acid) : High Molybdenum Levels in Herbage on (Dr. T. Walsh, M. Neenan and Dr. L. B. O'Moore), 1120
Solar Corona : Origin of the (J. H. Piddington and R. D. Davies), 692
  A Theoretical Model for Arches in the (Dr. J. W. Dungey), 618
Solar Daily Variation . World-wide Changes in the Phase of the Cosmic-Ray (T. Thambyahpillai and Dr. H. Elliot), 918
Solar Origin : Daily Variation of Meson Intensity and its Possible (V. Sarabhai, U. D. Desai and R. P. Kane), 122
Solar Radio Emission from Sunspots : A Method of Analysis of the Directivity of (T. Takakura), 445
Solar System, *review* by Prof. W. M. H. Greaves, 3
Solid into Ascites Tumours : Conversion of (Dr. George Klein), 398
Solid State · Physics of the (University of Bristol in co-operation with the International Union of Physics Conference on), 1142
Solid State Physics (Physical Society—Spring Meeting on), 156, 1055
Solids : Dislocations and the Theory of (Prof. N. F. Mott), 234
  Initiation and Growth of Explosion in Liquids and (F. P. Bowden and A. D. Yoffe), *review* by Dr. James Taylor, 186
Solids (Total) · Quantitative Estimation of the, in Fresh Whole Milk by Oxidimetry (Arthur G. Leggatt), 1028
Solids in River Water : Adsorption of DDT on Suspended, and its Role in Black-fly Control (F. J. H. Fredeen, A. P. Arnason and B. Berck), 700
Solomon's Ring (King) : New Light on Animal Ways (Konrad Z. Lorenz), translated from the German by Marjorie Kerr Wilson, *review* by T. H. H., 1133
Sols of Silver Iodide : Centrifugation Potentials in (Prof. A. J. Rutgers and P. Nagels), 568
Solution : Determination of the Relative Electrode Potential of an Uncharged Metal in (Dr. J. O'M. Bockris and R. Parry-Jones), 930
Solutions (Concentrated) : Activity Data and the Association of Hydrogen Chloride in (A. M. Posner), 519
Solutions of Non-Electrolytes : Equilibrium Properties of (Faraday Society General Discussion on), 462
Solutions containing Sugars . An Action of Strongly Basic Anion-Exchange Resins and (Dr. A. C. Hulme), 610
Solway Counties : Depopulation and Rural Life in the (Bertram Hutchinson), 643
Somatic Reduction Division in the Development of the Sea Urchin (Prof. Per Eric Lindahl), 437
Sound (Dr. H. F. Boulind), *review*, 765
Sound (W. Hall and O. M. Matthews), *review* by T. M. Yarwood, 54
Sound in Schools (R. M. Sillito), 779
Sound Recording and Reproduction (J. W. Godfrey and S. W. Amos), *review*, 587
South African Bantu · Serum Iron and Iron-binding Capacity in the (Th. Gerritsen and A. R. P. Walker), 699
South African Waters : The Shark, *Isurus oxyrinchus*, in (Prof. J. L. B. Smith), 977
South Asia : Bibliography of Scientific Publications of (South Asia Science Co-operation Office), No. 6, July–December 1951, 246
South Carolina : Flora and Fauna of, 677
South-West Africa · Absence of the Sickle Cell Trait in the Bushmen of (S. B. Griffiths), 577
South and South-East Asia : Technical Assistance to, 956
Sovereign · Science and the (Sir Arthur MacNalty), 951
Soviet Union : Recent Gegenschein Studies in the, 555
Space (*n*-Dimensional Vector) : Linear Transformations in (Prof. H. L. Hamburger and M. E. Grimshaw), *review*, 233
Spain : Chemistry and Physics in (Sir Eric Rideal), 915
Spark Source : Electronically controlled Spectrographic (Dr. Á. Bardócz), 1156
Species Formation in *Trifolium subterraneum* (R. D. Brock), 939
Specific Volume of Cellulose in Aqueous Solutions of Inorganic Salts (Dr. S. M. Neale and G. R. Williamson), 842
Specificity of the Chemically Modified '*Aspergillus niger β*-Glucosidase' : Relative (Dr. Yutaka Murakami), 522
Specimen Support Films : A New Method of Making Electron Microscope (D. E. Bradley), 1076
Spectra of Coals and Coal Products · Infra-Red (C. G. Cannon), 308
Spectrographic Spark Source : Electronically controlled (Dr. Á. Bardócz), 1156
Spectrometers (Double-Beam) : Optical Design of (E. F. Daly), 560
Spectrophotometer for Visible and Near Infra-red Radiation : New (Unicam Instruments (Cambridge), Ltd.), 200
Spectroscopy Direct-Reading Emission, 596
  Molecular Structure and (Symposium at the Ohio State University), 201
Spectrum and Structure of Iododiene : Microwave (Dr. A. H. Sharbaugh, G. A. Heath, L. F. Thomas and Dr. J. Sheridan), 87
Speeds (Supersonic) : Noise from Aircraft at (C. H. E. Warren), 214 ; (E. W. Bastin), 215 ; (P. Rothwell), 215 ; (Dr. E. Esclangon), 827
Sperm Speeds . A New Method of Measuring (Lord Rothschild), 512
Spermatogenesis in *Lumbricus terrestris* L., Mull. (Dilys Rawson), 264
Sphincter in the Umbilical Ring of the Rabbit (I. Maureen Young), 703
Sphingosin : Trans-Ethylenic Structure of (Prof. G. Fodor and J. Kiss), 651
Spider Crabs : Behaviour of, in the Presence of Octopuses (H. J. Beal), 887
Spiders : Insects and (H. Trevor Jones), *review* by T. H. H., 143
Spiers Memorial Lecture of the Faraday Society (Prof. J. H. Hildebrand), 462
Spinners and Sedges · Duns, *review* by Prof. J. W. Munro, 320
Spiritualism : Telepathy and (Dr. J. Hettinger), *review* by Dr. E. J. Dingwall, 320
*Spongomorpha* (Marine Alga) · Variability in the X-Ray Diagram of the Cell Walls of the (E. Nicolai and Dr. R. D. Preston), 752
Sporulating Anaerobes on English Flax (Esther Hellinger), 1119
Spraying Agent for Paper Chromatography of Carbohydrates and Polyols · A New (D. J. D. Hockenhull), 982
Spring Migration : Patterns of (T. H. Hawkins), 25
Springs of Action (Present Question Conference on), 867
Sputum (Human) . Separation of an Inhibitor of Influenza Virus Haemagglutination from (C. Curtain, Dr. B. P. Marmion and J. Pye), 33
Square Radius : Mean, of Randomly Coiled Molecular Chains (Dr. R. A. Sack), 310
Stain for some Fatty Materials (R. H. Harris), 332
Staining Bacteria on Microscope Slides : A New Method in (Prof. P. H. H. Gray), 1030
Staining of Nerve Fibres : Hyaluronidase as an Adjuvant to Methylene Blue in (Ian A. McGregor), 1070
Staining and Plastic Embedding of Small Mineralized Plant Fossils (Dr. Henning Horn af Rantzien), 516
Stains (Aqueous) : Permeability of Insect Cuticle to, and Vulnerability to Insecticides (S. Mukerji and S. N. Chatterjee), 119
Standards : Professional, in the Welfare State, 93
*Staphylococcus aureus* . A Coagulase-destroying Factor produced by variants of (Dr. Iwo Lominski, Douglas D. Smith and Robert B. Morrison), 214
Star-Pairs (Horrebow) : Catalogue of, for the Determination of Northern Latitudes, 505
Starch : Structure of (Prof. R. H. Hopkins), 429
Starch, Glucose and Fructose : Radioactive, from Tobacco Leaves (H. K. Porter and R. V. Martin), 505
Stars : Wave-lengths for Radial-Velocity Determinations of (K. O. Wright), 637
Stars (*O*- and *B*-Type) : Age and Evolution of the ζ Persei Group of (A. Blaauw), 1005
Stas Medal of the Société Chimique de Belgique presented to Prof. F. A. Paneth, 638
State (Modern) Social Adjustment in the, 49
State (Welfare) : Professional Standards in the, 93
State Support for Scientific Research, 895
Static Electrification (Institute of Physics Conference on), 20
Statistical Method in Transport Management (M. R. Sampford), 251
Statistical Methodology Reviews, 1941–1950 (edited by Prof. Oscar Krisen Buros), *review*, 496
Statistical Methods in Forest Research (J. N. R. Jeffers), 511
Statistical Methods and Operational Research in Transport (F. A. A. Menzler), 251
Statistical Nature of 'Facilitation' at a Single Nerve-Muscle Junction (Dr. J. del Castillo and Prof. B. Katz), 1016
Statistical Physics · Papers on the Basic Principles of (N. S. Krylov), *review* by Dr. R. Eisenschitz, 143
Statistics for Medical and other Biological Students (L. Bernstein and M. Weatherall), *review*, 278
Statistics and Probability (Mathematical) : Proceedings of the Second Berkeley Symposium on (edited by Jerzy Neyman), *review* by Prof. M. G. Kendall, 410, 463
Stearic Acid Crystals : Growth and Optical Properties of (P. M. Reynolds and Ajit Ram Verma), 486
Stephenson (Marjory) Memorial Lecture of the Society for General Microbiology (Dr. D. D. Woods), 290
Sterility · First World Congress on Fertility and, 245
  Infertility and (American Society for the Study of Sterility Prize for a contribution to the subject of), 156
Sterling Area, an American Analysis (John M. Cassels), *review* by Mrs. Ursula K. Hicks, 537
Sterling Area in American Eyes, *review* by Mrs. Ursula K. Hicks, 537
Steroids : The Determination of Adrenal Cortical, and their Metabolites (Society for Endocrinology Symposium on), 777
Steroids (Urinary) : Fluorometric Analysis of (Dr. M. Finkelstein), 254
4,4′-Stilbenediol : A New Synthesis of [illegible] Derivatives of (P. M. Bhargava and Dr. S. Husain Zaheer), 746

Stimuli during Shock: Response of the Vascular System to Sympathetic (A. G. B. Kovách and L. Takács), 433
Stomatal Behaviour in the Onion (O. V. S. Heath), 110
Stop-watches and Chronographs: Catalogue of (Camerer Cuss and Co.), 636
Storm Damage to Woodlands in Scotland on January 31, 1953 (Prof. H. M. Steven), 454
Strains (Cyclic): Softening of Cold-worked Metals under (N. H. Polakowski), 173
Stratosphere (Lower): Humidity of the Upper Troposphere and, over Southern England (J. K. Bannon, R. Frith and H. C. Shellard), 381
Strawberry Roots (Mycorrhizal): Fructifications associated with (Barbara Mosse), 974
Strawberry Viruses: Heat Inactivation of (Dr. A. F. Posnette), 312
Streptomycin-resistant Mutants in Dense Suspensions of *Brucella abortus* (Strain 19): A Growth-Inhibitor for (Dr. A. L. Olitzki), 132
Stress Pulses. Creep of Copper under (Dr. A. J. Kennedy), 927
Stresses: Internal, caused by Disorder in Vitreous Materials (H. Rawson), 169
Structural Features of Antitumorigenic Corticoids (Dr. Elvira Mardones, Dr. Rigoberto Iglesias and Prof. A. Lipschutz), 1026
Structural Linguistics. Methods in (Zellig S. Harris), *review* by Prof. Alan S. C. Ross, 1084
Structural Skeleton in a Bituminous Coal (Katsuya Inouye), 487
Structure of Algal Flagella (Prof. W. T. Astbury and Dr. N. N. Saha), 280
Structure of the Angiosperm Inflorescence Apex (Dr. John G. Vaughan and F. R. Jones), 751
Structure of Asparagine (Dr. S. J. Leach and Dr. H. Lindley), 1062; (Prof. F. C. Steward and Dr. J. F. Thompson), 1063
Structure of Coenzyme A (Dr. J. Baddiley, E. M. Thain, G. D. Novelli and F. Lipmann), 76
Structure of Collagen: The Nature and (Colloid and Biophysics Committee of the Faraday Society Discussion on), 110
Structure of Deoxyribonucleic Acid. Genetical Implications of the (J. D. Watson and F. H. C. Crick), 964
Structure of Glycosides: A New Procedure for Correlating the (M. Abdel Akher, J. E. Cadotte, R. Montgomery, Prof. F. Smith, J. W. Van Cleve and Bertha A. Lewis), 474
Structure of the Influenza Virus: Electron Microscope Studies of the (L. Hoyle, Dr. R. Reed and Prof. W. T. Astbury), 256
Structure of Iodosilane: Microwave Spectrum and (Dr. A. H. Sharbaugh, G. A. Heath, L. F. Thomas and Dr. J. Sheridan), 87
Structure of Magnesium-Lithium $\beta$-Phase Alloys (R. L. P. Berry and Prof. G. V. Raynor), 1078
Structure of the Nucleic Acids (Prof. Linus Pauling and Prof. Robert B. Corey), 346
Structure of Pollen, *review* by Dr. W. B. Turrill, 362
Structure of Proteins of the $\alpha$-Keratin Type: Compound Helical Configurations of Polypeptide Chains—(Prof. Linus Pauling and Prof. Robert B. Corey), 59
Structure of Starch (Prof. R. H. Hopkins), 429
Structure Reports for 1949 (edited by A. J. C. Wilson), Vol. 12, *review* by H. J. Grenville-Wells, 1084
Strychnine as a Depressant of Primary Inhibition (K. Bradley and Prof. J. C. Eccles), 1061
Students: Physics Monographs for, *review* by S. Weintroub, 1132
Students (Medical and other Biological): Statistics for (L. Bernstein and M. Weatherall), *review*, 278
Students' Medal and Prize for 1952 of the Institute of Fuel awarded to B. H. Holland, 1054
Studentship in Geophysics: Research (Royal Dutch-Shell Group), 729
Studentships: MacKinnon Research (Royal Society Awards), 66
  Research (Trinity College, Cambridge), 377
Studentships in Zoology: Research (Zoological Society of London), 638
*Studies in Conservation*, No. 1, 199
Study in the United States: Commonwealth Fund Fellowships for, 776
Sublimation (Short-path): A Simple Tissue Freeze-drying Apparatus using the Principle of (Dr. L. O. Butler and Dr. L. G. E. Bell), 971
Subspecific Differences between Naples and Plymouth Populations of *Ophryotrocha puerilis*. Genetic and Morphological Evidence for (Dr. Guido Bacci and Dr. Marcello La Greca), 1115
Substance *P* in the Central and Peripheral Nervous System: Distribution of (Dr. Bengt Pernow), 746
Substances naturelles de synthèse (Collection publiée sous la direction de Dr. Léon Velluz), Vol. 4, *review* by Prof. W. Baker, 496
Substitute Fibres: Jute (A. E. Haarer), *review* by Sir Geoffrey Evans, 535
Substitution. Laws of Addition and, in Atomic Reactions of Halogens (Jean Adam, P. A. Gosselain and Prof. P. Goldfinger), 704
Substrates. Dehydrogenation of various, by *Vibrio cholerae* (A. Dudani, S. N. Iyer, C. R. Krishna Murti and D. L. Shrivastava), 81
Succinic Acid Oxidase System: Effect of Acetoacetate on the (Prof. M. C. Nath and V. G. Hatwalne), 1158
Succinic Dehydrogenase. Histochemistry of (Dr. H. A. Malaty and Dr. G. H. Bourne), 295
Succinoxidase Inhibition by Surface-active Agents. Curves of (Dr. Sumner M. Kalman), 568
Sudden-Death Disease of the Clove Tree, *Eugenia aromatica* (Dr. F. J. Nutman and F. M. Roberts), 128
Sugars: An Action of Strongly Basic Anion-Exchange Resins and Solutions containing (Dr. A. C. Hulme), 610
  Degradation of, on Ion-Exchange Columns of 'Amberlite IRA 400 (OH')', (J. D. Phillips and Dr. A. Pollard), 41
  Use of Ion-Exchange Resins in Paper Chromatography of (Dr. L. I. Woolf), 841
  Use of Unneutralized Hydrolysates in Paper Chromatography of (Blanche D. E. Gaillard), 1160
Sugars (Hexose): Interference of Pentose in the Estimation of, with Anthrone (R. Johanson), 176
  Radioactive Starch and, 505
Sulphaguanidine: Influence of, on the Intestinal Flora and Thiamine Syntheses brought about by Curd Feeding (S. Balakrishnan and Dr. R. Rajagopalan), 608
Sulphate-reducing Bacteria: Cultivation of (Joy P. Grossman and Dr. John R. Postgate), 600
Sulphates in African Inland Waters (R. S. A. Beauchamp), 769
Sulphonation and Nitration in an Aromatic Nucleus: Simultaneous (A. Bryson and J. L. Garnett), 41
Sulphur-containing Amino-acids of Nisin (G. G. F. Newton, Dr. E. P. Abraham and Dr. N. J. Berridge), 606
Sulphydryl Reactants on Liver Ribonuclease: Effect of (Jay S. Roth), 127
Summer School in the Use of Electrons for the Examination of Metals (University of Cambridge in co-operation with the Institute of Metals), 867
Summer School in Optical Crystallographic Methods: Postgraduate (Department of Inorganic and Physical Chemistry of the University of Leeds in association with the Department of Adult Education and Extra-Mural Studies), 822
Summer School on Welding and Fabrication (British Welding Research Association), 111
Sun: Planetary Influences on the (M. Kopecký, P. Mayer and V. Borovičková), 956
  Total Eclipse of the, on June 30, 1954, 505
Sunspot Number Series (R. N. Bracewell), 649
Sunspots: A Method of Analysis of the Directivity of Solar Radio Emission from (T. Takakura), 445
Superconductivity in Thin Tin Films: Measurements on (Prof. A. Van Itterbeek, L. De Greve, L. Van Gerven and J. Schepers), 834
Supersonic Bang: The (G. M. Lilley, R. Westley, A. H. Yates and J. R. Busing), 994
Supersonic Speeds: Noise from Aircraft at (C. H. E. Warren), 214; (E. W. Basdin), 215; (P. Rothwell), 215; (Dr. E. Esclangon), 827
Suppression of Prototrophs: Competitive (Dr. Francis J. Ryan), 400
Suprarenal Cortex: Cortisone and the (Società Italiana di Reumatologia Symposium on), 463
Suprarenal Medulla. Influence of the Blood Glucose-Level on the Secretion of Adrenalin and Noradrenalin from the (Hans Dunér), 481
Surface Free-Energy of Solid Paraffin Wax (E. B. Greenhill and S. R. McDonald), 37
Surface Photometry of Southern Elliptical Nebulae (Dr. David S. Evans), 913
Surface-active Agents: Curves of Succinoxidase Inhibition by (Dr. Sumner M. Kalman), 568
Swarming of *Nereis succinea* (Leuckart) off the East Coast of Canada (C. Berkeley and E. Berkeley), 847
Sweden: Study of Forest Seeds in, 419
Swift: Breeding Behaviour of the (David and Elizabeth Lack), 382
Symbols in the Child's Mind: Formation of, *review* by Prof. John Cohen, 450
Symmetric Agents: Natural Origin of Optically Active Substances and Optical Resolution by (Prof. John Read), 843
Symmetrical Agents: Resolution of Racemic Mixtures by (Ricardo Carvalho Ferreira), 39
Symmetry (Hermann Weyl), *review* by F. I. G. Rawlins, 1037
Symons Memorial Medal for 1953 of the Royal Meteorological Society awarded to Prof. Carl-Gustav Rossby, 866
Synchrotron (Strong-focusing): Effect of Magnet Inhomogeneities in the (J. B. Adams, Dr. M. G. N. Hine and J. D. Lawson), 926
Synthèse: Substances naturelles de (Collection publiée sous la direction de Dr. Léon Velluz), Vol. 4, *review* by Prof. W. Baker, 496
Synthesis. (Haemoglobin): Influence of Temperature and Iron on, by *Daphnia* (Prof. H. Munro Fox, Elizabeth A. Phear and Barbara M. Gilchrist), 347
Synthesis (Protein): Possible Role of Proteolytic Enzymes in (Robert B. Loftfield, John W. Grover and Mary L. Stephenson), 1024
Synthesis of Acetoacetate: Enzymatic Breakdown and (Dr. Joseph R. Stern, Dr. Minor J. Coon and Miss Alice Del Campillo), 28
Synthesis of L-Ascorbic Acid in Plants and Animals (Dr. F. A. Isherwood, Mrs Y. T. Chen and Dr. L. W. Mapson), 348
Synthesis of 'Block' Copolymers. A Flow Method for the (J. A. Hicks and Prof. H. W. Melville), 300
Synthesis of 2-Deoxy-D-ribose: A New (Y. Matsushima and Y. Imanaga), 475
Synthesis of some Derivatives of 4,4′-Stilbenediol: A New (P. M. Bhargava and Dr. S. Husain Zaheer), 746
Synthesis of Electronic Computing and Control Circuits (Staff of the Computation Laboratory of Harvard University), *review* by M. V. Wilkes, 453
Synthesis of Quaternary Compounds possessing Lasting Local Anaesthetic Action (Dr. K. Nádor, F. Herr, Gy. Pataky and J. Borsy), 788
Synthetic Detergents: Committee on the Effects of, 912
Synthetic Fibres. Drawing (I. Marshall and A. B. Thompson), 38
Synthetic Fluorocitric Acid. Fluoroacetate Poisoning—Comparison of, with the Enzymically Synthesized Fluorotricarboxylic Acid (Sir Rudolph Peters, R. W. Wakelin, D. E. A. Rivett and L. C. Thomas), 1111
Synthetic Graphite: Closed Pores in (Miss E. M. Dresel and Dr. L. E. J. Roberts), 170
Synthetic Polymers (Crystalline): Morphology of (A. Keller), 170
Synthetic Polypeptides: $\beta$-Forms of Fibrous Proteins and (Dr. C. H. Bamford, L. Brown, Dr. A. Elliott, W. E. Hanby and I. F. Trotter), 1149
Synthetic Soil Conditions: 'Krilium' and (Prof. J. H. Quastel), 7

*Taeniorhynchus* (*Mansonioides*) *uniformis* (Theobald): Nocturnal Mating in (Dr. S. H. Jayewickreme), 577
Tainting of Tobacco by a Dichloropropene-Dichloropropane Soil Fumigant (R. McChlery), 578
Tajín Totonac (Isabel Kelly and Angel Palerm), Part 1, History, Subsistence, Shelter and Technology, 686
Tannic Acid and 2-Acetylaminofluorene: Rapid Production of Malignant Hepatomas by Simultaneous Administration of (Dr. Martha Mosonyi and Dr. Béla Korpássy), 791
Tarpan: Breeding-back of the, 1008
Tarsier, *Tarsius carbonarius*: Natural History and Parasites of the (W. C. Osman Hill, Annie Porter and Margaret D. Southwick), 18
Taxonomy: Botanical, *review* by J. S. L. Gilmour, 585
  A Possible New Principle in, and its Evolutionary Implications (R. A. Crowson), 883

# TITLE INDEX

Taxonomy of Vascular Plants (Prof. George H. M. Lawrence), *review* by J. S. L. Gilmour, 585
Taxonomy of the Yeasts, *review* by Prof. Öjvind Winge, 989
Technical Articles on Radio : Awards for (Radio Industry Council), 200
Technical Assistance to South and South-East Asia, 956
Technical Information : Presentation of (J. W. Godfrey), 728
Technical Publications, 1947 (Members of the Standard Oil Co. (New Jersey) and affiliated organizations), *review*, 278
Technical Resources of Industrial Firms, 676
Technical Words : An Explaining and Pronouncing Dictionary of Scientific and (Dr. W. E. Flood and Dr. Michael West), *review* by W. L. Sumner, 993
Technics : Art and (Lewis Mumford), 359
Technological Society : Education in a (Unesco Tensions and Technology Series), 533, 964
Technologists in Great Britain : Recruitment of Scientists and, 866
Technology : Impact of, on Society, 359
  The Promise of (Resources for Freedom, a Report to the President by the President's Materials Policy Commission, Vol. 4), 1
  X-Ray Crystallography in, *review* by Dr. W. A. Wooster, 586
Technology (Modern) : The Community Factor in (Jerome F. Scott and R. P. Lynton), 533
*Telanthropus capensis* : The Nature of (J. T. Robinson), 33
Teleosts . Thyroid Activity in (P. Y. Fortune), 483
Telepathy and Spiritualism (Dr. J. Hettinger), *review* by Dr. E. J. Dingwall, 320
Telescope : Wilfred Hall, 154
Telotrematous Brachiopoda : Orientation of (Prof. E. Percival), 436
Temperature : Effect of, on the Conductivity induced in Insulators by X-Rays (J. F. Fowler and Dr. F. T. Farmer), 1020
Temperature of the Chromosphere, 375
Temperature of the Interior of the Earth (Prof. J. A. Jacobs), 835
Temperature of the Upper Atmosphere : Cosmic-Ray Intensity and the (Harald Trefall), 888
Temperature and Iron : Influence of, on Hæmoglobin Synthesis by *Daphnia* (Prof. H. Munro Fox, Elizabeth A. Phear and Barbara M. Gilchrist), 347
Temperatures : Tertiary Ocean Bottom (C. Emiliani and G. Edwards), 887
Temperatures of Metal/Mould Interfaces : Measurement of (D. V. Atterton and D. H. Houseman), 980
Template Theory and the Role of Transpeptidation in Protein Biosynthesis (Dr. C. E. Dalgliesh), 1027
Tensile Strength of Liquid Nitrogen (Prof. A. D. Misener and F. T. Hedgcock), 835
Tensor Analysis, Theory and Applications (Prof. I. S. Sokolnikoff), *review*, 279
Teoria moderna dell' integrazione : Lezioni sulla (Prof. Mauro Picone e Tullio Viola), *review* by Prof. H. T. H. Piaggio, 452
*Teredo norvegica* : Vertical Distribution of (G. Owen), 484
Terminology in Bacterial Genetics (Prof. Boris Ephrussi, Dr. Urs Leopold, Dr. J. D. Watson and Prof. J. J. Weigle), 701
Terpenes : The (Sir John Simonsen and Dr. D. H. R. Barton), second edition, Vol. 3, The Sesquiterpenes, Diterpenes and their Derivatives, *review* by Prof. John Read, 233
Terrestrial Magnetic Storms : Radio Echoes observed during Aurorae and, using 35 and 74 Mc./s. Waves Simultaneously (Prof. L. Harang and B. Landmark), 1017
Tertiary Ocean Bottom Temperatures (C. Emiliani and G. Edwards), 887
Tetanus Toxoid : Rapid Specific Preventive Action of (M. Raynaud and E. A. Wright), 797
Textile Institute Medal awarded to Walter English, 463
Textile Technology : Cotton Industry War Memorial Trust Scholarship in (Textile Institute), 506
*Theileria parva* Infection : Aureomycin in (Dr. W. O. Neitz), 34
Theoretical Approach to the Problem of determining the Relationship between the Constants of Circuits and their Intrinsic Safety (Dr. B. Roston), 397
Theory of Functions of a Real Variable (Prof. R. L. Jeffery), *review* by Prof. H. T. H. Piaggio, 452
Theory of Games (Dr. S. Vajda), 779
Theory of Relativity (Prof. C. Møller), *review* by Prof. J. L. Synge, 140
Theory of Solids : Dislocations and the (Prof. N. F. Mott), 234
Therapeutic Action of Glutathione and Mercaptoethylamine against a Lethal Dose of X-Rays (Prof. J. H. Maisin, G. Lambert, M. Mandart and H. Maisin), 971
Thermal Analysis (Differential) . Bibliography of (Prof. W. J. Smothers, Y. Chiang and A. Wilson), 244
Thermal Decomposition of Ethyl Nitrate : Effect of Nitric Oxide on the (Dr. F. H. Pollard, H. S. B. Marshall and A. E. Pedler), 1154
Thermal Degradation of Polystyrene (Paul D. Zemany), 391
Thermistors . Molecular Weight Determination by (Dr. S. B. Kulkarni), 219
Thermochromism and Keto-Enol Tautomerism of Solutions of 1 : 3-Diketo-2-phenyl-5-bromoindan (Prof. A. Schonberg, Dr. A. Mustafa and Dr. W. Asker), 222
Thermodynamics of Equilibrium and Non-Equilibrium States : Summer Course in the (Massachusetts Institute of Technology), 729
Thermodynamics and Kinetics (Electrochemical) : International Committee for—Meeting in London, 23
Thermometry : Fundamentals of (J. A. Hall), *review* by S. Weintroub, 1132
  Practical (J. A. Hall), *review* by S. Weintroub, 1132
Thiamine Synthesis brought about by Curd Feeding : Influence of Sulphaguanidine on the Intestinal Flora and (S. Balakrishnan and Dr. R. Rajagopalan), 608
Thioureas : Paper Chromatography of (Dr. Anders Kjaer and Kurt Rubinstein), 840
Thornthwaite Forest, Cumberland (Prof. E. P. Stebbing), 557
Threads of the Sea Anemone, *Adamsia rondeletii* Purple Pigment and Protein in the (Prof. Anast. Christomanos), 886
'Three Group Metaphases' in the Bone-Marrow of the Golden Hamster : Production of (Dr. R. Parmentier), 1029
Thymus Extract (Calf) Vitamin $B_{12}$ Content of (W. J. Kaipainen, Dr. Antti Telkkä and Kimmo K. Mustakallio), 845
Thyroid Activity in Teleosts (P. Y. Fortune), 483
Thyroid Gland (Society for Endocrinology and the Endocrinological Section of the Royal Society of Medicine Symposium on), 551
  Effect of, on the Cultivation of *Amœba proteus* (Sister Monica Taylor), 313
Tian–Calvet Microcalorimeter in Seed Germination Studies (Prof. H. Prat), 24
Timber Trees : Pocket Check List of (J. Wyatt-Smith), 461
Timbers (Indian) : Seasoning Behaviour of (M. A. Rehman), 534
Tin Films : Measurements on Superconductivity in Thin (Prof. A. Van Itterbeek, L. De Greve, L. Van Gerven and J. Schepers), 834
Tissue (Silicotic) : Formation of (Dr. P. F. Holt and S. G. Osborne), 892
Tissue Freeze-drying Apparatus using the Principle of Short-path Sublimation : A Simple (Dr. L. O. Butler and Dr. L. G. E. Bell), 971
Tissue Grafts (Normal) : Storage of, 1047
Tissue Potentials in Man : Effect of Cortisone on (Geoffrey E. Loxton and David Le Vay), 524
Tissues (Normal) : Preservation of, for Transplantation (Ciba Foundation Symposium on), 1047
Titanium : Preparation of Single Crystals of, and their Mode of Deformation (Dr. A. T. Churchman), 706
Tobacco A New Linkage in (Dr. B. S. Kadam and B. Radhakrishnamurthy), 1028
  Tainting of, by a Dichloropropene-Dichloropropane Soil Fumigant (R. McChlery), 578
Tobacco Infected with Potato Virus Y : Infectivity of Aphids after Several Hours on (Dr. R. H. E. Bradley), 755
Tobacco Leaves : Radioactive Starch, Glucose and Fructose from (H. K. Porter and R. V. Martin), 505
Tobacco Mosaic Virus : Occurrence in Plants infected with, of a Crystallizable Antigen devoid of Ribonucleic Acid (Prof. R. Jeener and P. Lemoine), 935
  Incorporation of 8-Azaguanine into Nucleic Acid of (Dr. R. E. F. Matthews), 1065
Tobacco Trashy Leaf : Differential Fluorescence in Identification of (R. Johanson), 753
Tobago : The Useful and Ornamental Plants in Trinidad and (revised fourth edition by R. O. Williams and R. O. Williams, Jr. ; original edition by W. G. Freeman and R. O. Williams), *review*, 52
Tomato Virus-induced Nucleolar Abnormalities in (Dr. John Wilkinson), 658
Tomato Plants at Different Phases of Growth : Manganese Requirements of (M. Bakr Ahmed and Prof. E. S. Twyman), 438
Tomatoes under Glass : Effects of Different Water-regimes on the Growth of (J. P. Hudson and P. J. Salter), 480
Towed Electrodes : Measurement of Wind Currents in the Sea by the Method of (K. F. Bowden), 735
Toxic Substances : Effects of, on Wild Life, 820
  Handling of Radioactive and (Atomic Energy Research Establishment Symposium on), 294
Toxicity of Chlorinated Phenyl Benzenesulphonates to Winter Eggs of the Fruit Tree Red Spider Mite, *Metatetranychus ulmi* (Koch), (Dr. A. H. M. Kirby and R. P. Tew), 479
Toxoid (Tetanus) : Rapid Specific Preventive Action of (M. Raynaud and E. A. Wright), 797
Tracers in Chemical Dosimetry : Use of (Gosta Rudstam and Prof. The Svedberg), 648
Trade in Agricultural Machinery : A Survey of the (Commonwealth Economic Committee), 199
Tradition and the Coronation (Archibald G. B. Russell), 948
Trafalgar Square : The Fountains in, some Reflections on the Civil Service (C. K. Munro), *review* by R. Brightman, 362
Training Centre : A Model Rehabilitation and, 866
Transaminase Systems in the Alga *Chlorella* : Demonstration of (J. W. Millbank), 476
Transamination Reaction : A New (L. Fowden and J. Done), 1068
Trans-Ethylenic Structure of Sphingosin (Prof. G. Fodor and J. Kiss), 651
Transfer : Passive, of Transplantation Immunity (N. A. Mitchison), 267
Transformation of Retained Austenite by Fracture . An X-Ray Diffraction Study of the (L. W. Pateman and H. S. Peiser), 696
Transglucosylation of Aromatic N-Glucosidase (Prof. R. Bognár and P. Nánási), 475
Transliteration of Cyrillic Script (M. Aurousseau), 940
Transliteration of Russian, Serbian and Bulgarian for Bibliographical Purposes (Royal Society), 548
Transmission-like Reflection Fringes in Birefringent Crystals (Ajit Ram Verma), 396
Transoximation : Enzymatic (Prof. Kazuo Yamafuji), 745
Transpeptidation in Protein Biosynthesis : The Template Theory and the Role of (Dr. C. E. Dalgliesh), 1027
Transplantation : Preservation of Normal Tissues for (Ciba Foundation Symposium on), 1047
Transplantation Immunity : Passive Transfer of (N. A. Mitchison), 267
Transport : Active (Society for Experimental Biology Symposium on), 1142
  Statistical Methods and Operational Research in (F. A. A. Menzler), 251
Transport Coefficients : Intermolecular Force and (B. N. Srivastava and M. P. Madan), 441
Transport Management : Statistical Method in (M. R. Sampford), 251
Travelling Disturbances in the Ionosphere—Diurnal Variation of Direction (G. H. Munro), 693
Trawling : Deep-sea (Dr. O. Nybelin), 595
Tree Seedlings : Effect of Galvanized Iron on some (J. Hawkins and D. I. Cameron), 977
Trees : Wild Flowers, Grasses, Ferns, Fungi, (H. Trevor Jones), *review* by T. H. H., 143
Trees (Timber) : Pocket Check List of (J. Wyatt-Smith), 461
Trees of the Uganda Protectorate The Indigenous (Dr. William J. Eggeling), revised and enlarged by Ivan R. Dale, *review* by R. W. J. Keay, 856
Trematode Genus *Renicola* Cohn : Probable Relationship between the *Rhodometopa* Group of Cercariae and the (C. A. Wright), 1072
Trematode Metacercaria from the Eyes of Trout : A New (Dr. M. B. Lal), 130
Treponemal Immobilization Test : Elimination of Inconclusive Results in the (Hans Aage Nielsen), 1030
Tributyrin : Oat Lipase and (F. G. Peers), 981

Trichloroacetic Acid : Effects of, on the Extension Growth of Root and Shoot Segments of *Pisum sativum* (Sen Gita and E. K. Woodford), 936
*Trichomonas foetus* : Serum as a Source of Growth-Factors for (J. K. Clausen), 1067
*Trifolium alexandrinum* : Effect of Boron and Molybdenum Fertilizers on Berseem (N. P. Datta and H. Gurubasava Raj), 134
*Trifolium ambiguum* : Effect of Grafting on Nodulation of (F. W. Hely, Ch. Bonnier and P. Manil), 884
*Trifolium subterraneum* : Species Formation in (R. D. Brock), 939
Trigonometric Series used in Physical Problems (S. K. Lakshmana Rao and B. S. Ramakrishna), 308
Trinidad and Tobago : The Useful and Ornamental Plants in (revised fourth edition by R. O. Williams and R. O. Williams, Jr. ; original edition by W. G. Freeman and R. O. Williams), *review*, 52
Trinitratouranyl Complex Ion (Dr. C. C. Addison and N. Hodge), 569
Tropane Alkaloids : Conformation of (Dr. Ajay K. Bose and Dilip K. Roy Chaudhuri), 652
Tropical Hygiene for Laymen : Course in (Ross Institute of Tropical Hygiene), 333
Tropics : Housing in the (United Nations, Department of Social Affairs, Town and Country Planning Bulletin No. 6), 461
  Useful Plants of the, *review*, 52
Troposphere (Upper) : Humidity of the, and Lower Stratosphere over Southern England (J. K. Bannon, R. Frith and H. C. Shellard), 381
Trout : A New Trematode Metacercaria from the Eyes of (Dr. M. B. Lal), 130
Trout Eggs and Larvae : Effect of Changing *p*H on Developing (Prof. Daya Krishna), 434
Trypan Blue : Influence of, on the Number of Circulating Eosinophils in Rats (Dr. Ines Wesley), 266
Trypsin : Crystalline (Dr. M. Bier and Prof. F. F. Nord), 1022
Tube : A Device for Counting Small Particles suspended in a Fluid through a (Dr. P. J. Crosland-Taylor), 37
Tubercle Bacilli (Avian) : Action of Antibiotics on, studied with the Electron Microscope (E. M. Brieger, Dr. V. E. Cosslett and Audrey M. Glauert), 211
Tuberculosis : Causes and Prevention of (Dr. Brice R. Clarke), *review* by Dr. J. G. Scadding, 626
  Dorothy Temple Cross Research Fellowships in (Medical Research Council), 111
Tumour Growth : Inhibition of, by D-Glucosamine (Prof. J. H. Quastel and Dr. A. Cantero), 252
Tumours : Conversion of Solid into Ascites (Dr. George Klein), 398
Tumours Induced by Ultra-violet Radiation : Application of the Quantum Hit Theory to (Simon Iversen and Dr. Niels Arley), 257
Turbulence : Damping of, by a Magnetic Field (W. Murgatroyd), 217
Turkish Earthquake of March 18 (Ernest Tillotson), 557
Tweed Valley : Depopulation and Rural Life in the (Bertram Hutchinson), 643
Twentieth Century : British Scientists of the (J. G. Crowther), *review* by W. L. Sumner, 97
3-Iodo-Tyrosine and 3 . 5-Di-iodo-Tyrosine : Artefacts produced from, by Heating with Alkali (P. G. Stanley), 933

UGANDA : The Pleistocene Geology and Prehistory of, Part 2, Prehistory (Dr. C. van Riet Lowe), *review* by M. C. Burkitt, 4
Uganda Protectorate : The Indigenous Trees of the (Dr. William J. Eggeling), revised and enlarged by Ivan R. Dale, *review* by R. W. J. Keay, 856
Ultrasonic Velocities in Liquids : A New Precision Method for the Measurement of (Dr. B. Ramachandra Rao and K. Subba Rao), 1077
Ultrasonics : Optics and (Physical Society Summer Provincial Meeting on), 867
Ultra-violet Absorption of Anthracene : Polarized (Dr. D. P. Craig and P. C. Hobbins), 566
Ultra-violet Illumination for Amphibian Blood Circulation : A Cinematographic Technique, using (J. R. Simons and Dr. A. R. Michaelis), 801 ; (G. E. H. Foxon), 801
Ultra-violet Irradiation : Susceptibility of Catalase-negative Bacteria to (Sidney Mittler and John A. Laverty), 793
Ultra-violet Light : 'Parathion' and (Miss J. Payton), 355
Ultra-violet Radiation : Application of the Quantum Hit Theory to Tumours Induced by (Simon Iversen and Dr. Niels Arley), 257
Umbilical Ring of the Rabbit : A Sphincter in the (L. Maureen Young), 703
Uncharged Metal in Solution : Determination of the Relative Electrode Potential of an (Dr. J. O'M. Bockris and R. Parry-Jones), 930
Unemployment in Lancashire : Social Security and (Political and Economic Planning, Broadsheet No. 349), 382
United Nations : Looking at the, 504
United Nations in Pictures, 504
United States : Agriculture in the, 374
  Development of Mineral Resources in the, 155
  Industrial Chemical Equipment in the (Prof. H. E. Watson), 204
  Oceanography in the (F. S. Russell), 71
  Research Expenditure in the, 727
  Rumford Bicentenary Celebrations in the (American Academy of Arts and Sciences), 376, 915
  Study of Psychology in the (American Psychological Association), 110
U.S.A. : Chemical Apparatus in the (Office of European Economic Co-operation, Technical Assistance Mission No. 23), 204
Universal Copyright Convention (Unesco), 956
Universe : Prize for an essay on the (Philosophy of Science Group of the British Society for the History of Science), 1098
Universities : Extra-mural Function of (Thomas Kelly), 776
  Report of the Conference on Industry and the (Federation of British Industries (North Midland Regional Council) and the University of Nottingham, September 1952), 962
Universities (British) : Scientific Research in, during 1951–52, 109
Universities of the Commonwealth, 1953 : The Yearbook of the (published for the Association of Universities of the British Commonwealth), *review*, 1039
Universities in Adult Education, 759
  Role of, 805
Universities in Great Britain : Autonomy of, 273
  Government Assistance to (Memoranda submitted to the Commission on Financing Higher Education by Harold W. Dodds, Louis M. Hacker and Lindsay Rogers), 273
Universities and Industry Conference : Report of the (Federation of British Industries and the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom, October 1952), 870
University : Fundamental and Applied Research in relation to the (Dean Ernest R. Hilgard), 289
University Botanical Teaching and Training (Prof. V. J. Chapman), 314 ; (Prof. N. P. Badenhuizen), 314
University Graduates in Industry : The Place of, 870
University Research : General Principles of, 289
Unorthodox : Academic Freedom and the, 663
Unpublished Mathematical Tables : Depository of (Royal Society), 1140
Unusual Form of Carbon (W. R. Davis, R. J. Slawson and Dr. G. R. Rigby), 756
Unvernalized Embryos : Accelerating Effect of an Extract of Vernalized Embryos of Winter Rye on Flower Initiation in (O. N. Purvis and Prof. F. G. Gregory), 687
Upwelling in the Benguela Current (Ronald Currie), 497
Uranium-Graphite Lattices : A Quantitative Study of (Prof. E. A. Guggenheim and Prof. M. H. L. Pryce), revised edition edited by C. A. Rennie, 110
Urea Complexes of Rape-oil Fatty Acids (J. H. Skellon and C. G. Taylor), 266
Urinary Steroids : Fluorometric Analysis of (Dr. M. Finkelstein), 254
Urine : A Rapid Method for the Extraction of Radioiodide from (D. G. Arnott and J. Wells-Cole), 269
Urushiol, Cardanol and Cardol (Poison Ivy) : Separation and Structure Determination of the Olefinic Components of (W. F. Symes and Prof. C. R. Dawson), 841
U.S.S.R. : Abstracting and Library Work in the (W. G. Cass), 555
Uterine Infection : Influence of Ovarian Hormones on (L. E. Rowson, G. E. Lamming and R. M. Fry), 749

VACUUM (High) : Methods of obtaining, by Ionization—Construction of an 'Electronic Pump' (Dr. Helmut Schwarz), 600
Variability (Environmental) : Analysis of, in Quantitative Inheritance (E. C. R. Reeve and F. W. Robertson), 874
Variable (Real): The Theory of Functions of a (Prof. R. L. Jeffery), *review* by Prof. H. T. H. Piaggio, 452
Variation of Meson Intensity : Daily, and its Possible Solar Origin (V. Sarabhai, U. D. Desai and R. P. Kane), 122
Variation in the Plankton and Salinity of the Hauraki Gulf, New Zealand : Seasonal (A. S. Fuller), 525
Vascular System : Response of the, to Sympathetic Stimuli during Shock (A. G. B. Kovách and L. Takács), 433
Vector Space (*n*-Dimensional) : Linear Transformations in (Prof. H. L. Hamburger and M. E. Grimshaw), *review*, 233
Végétales de la Plaine de la Ruzizi en relation avec le milieu : Les associations (R. Germain), 154
Vegetation in Africa : Management and Conservation of, *review* by Sir Edward Salisbury, 496
Vegetation of Ireland : Flora and, *review* by Prof. P. W. Richards, 1085
Vegetation and Man : Habitat, (Prof. W. H. Pearsall), 367
Velocities in Liquids : A New Precision Method for the Measurement of Ultrasonic (Dr. B. Ramachandra Rao and K. Subba Rao), 1077
Vendaland : A Dug-out Canoe in use in (Dr. A. C. Hoffman), 867
Verity : Joy and, other Poems and a Poetic Drama (Dr. Marie C. Stopes), *review* by F. K., 900
Vernalized Embryos of Winter Rye : Accelerating Effect of an Extract of, on Flower Initiation in Unvernalized Embryos (O. N. Purvis and Prof. F. G. Gregory), 687
Vertebrates : Neurosecretory Pathways in the Head of Crustaceans, Insects and (Prof. Bertil Hanström), 72
Vertical Distribution of Radium in Deep Sea Sediments (Dr. Viktor Sa. Kroll), 742
Vertical Distribution of *Teredo norvegica* (G. Owen), 484
*Verticillium* in Potato Tubers in India : Occurrence of (Prof. K. S. Bhargava and Hari Kishore), 800
*Verticillium albo-atrum* : Resistance of Hop Stems to Invasion by (W. G. Keyworth), 656
Very-High-Frequency Propagation : Multiple Bursts of Signal in Long-Distance (G. A. Isted), 617
Vesalius on the Human Brain (Charles Singer), *review* by Prof. F. J. Cole, 899
Vesicular Laterite (G. ap Griffith), 530 ; (E. J. Wayland), 1079
*Vibrio cholerae* : Dehydrogenation of various Substrates by (A. Dudani, S. N. Iyer, C. R. Krishna Murti and D. L. Shrivastava), 81
Victoria Medal of the Royal Geographical Society awarded to Sir John Myres, 635
Vienna Circle, the Origin of Neo-Positivism (Prof. Victor Kraft), translated from the German 'Der Wiener Kreis' by Arthur Pap, *review* by P. L. G. Rawlins, 947
Virology : Some Present Problems in (Centre de Collections de Types Microbiens de l'Institut d'Hygiène et de Bactériologie Symposium on), 463
Virus (Influenza) : Electron Microscope Studies of the Structure of the (L. Hoyle, Dr. R. Reed and Prof. W. T. Astbury), 256
  Growth of, in the Chick Chorion (Alick Isaacs and Dr. Forrest Fulton), 90
Virus (Tobacco Mosaic) : Incorporation of 8-Azaguanine into Nucleic Acid of (Dr. R. E. F. Matthews), 1065
  Occurrence in Plants Infected with, of a Crystallizable Antigen devoid of Ribonucleic Acid (Prof. R. Jeener and P. Lemoine), 935
Virus Haemagglutination (Influenza) : Separation of an Inhibitor of, from Human Sputum (C. Curtain, Dr. B. P. Marmion and J. Pye), 33
Virus Infection (Leaf Roll) : Effect of, on the Soluble Nitrogen Composition of Potato Tubers (R. M. Allison), 573
Virus-induced Nucleolar Abnormalities in Tomato (Dr. John Wilkinson), 659
Viruses (Cold Spring Harbor Eighteenth Symposium on Quantitative Biology), 333

Viruses (Caprinized and Lapinized Rinderpest) : Recovery of, from Condensed Water Vapour removed during Desiccation (A. L. C. Thorne), 609
Viruses (Influenza) . Genetic Interaction between (Sir Macfarlane Burnet, K. B. Fraser and Patricia E. Lind), 163
Viruses (Myxoma and Fibroma) : Classification of (Prof. Frank Fenner), 562
Viruses (Strawberry) . Heat Inactivation of (Dr. A. F. Posnette), 312
Viscosity (Relative) · Relationship between, and Volume Concentration of Stable Suspensions of Spherical Particles (D. R. Oliver and Prof. Stacey G. Ward), 396
Vision (Colour) . 'Maxwell's Spot' in, review by Prof. W. D. Wright, 5
Vision (Foveal Color) · New Means of Studying Color Blindness and Normal (G. L. Walls and R. W. Mathews), review by Prof. W. D. Wright, 5
Visual Cortex Pattern Discrimination and the (D. A. Sholl and A. M. Uttley), 387
Vitamin $B_{12}$ Active Compounds : Differentiation of, by Ionophoresis and Microbiological Assay—Ionophoresis (Dr. E. S. Holdsworth), 148 ; Microbiological Tests (J. E. Ford), 149 ; Occurrence of the various Vitamin $B_{12}$ Active Compounds (J. E. Ford, Dr. E. S. Holdsworth, Dr. S. K. Kon and Dr. J. W. G. Porter), 150
Vitamin $B_{12}$ Content of Calf Thymus Extract (W. J. Kaipainen, Dr. Antti Telkka and Kimmo K. Mustakallio), 845
Vitamin $B_{12}$ Content of Cow's Milk during the Last Month Indoors and the First Week at Pasture : Differences in the (E. E. van Koetsveld), 483
Vitamin C and Bone (Bone and Tooth Society Symposium on), 596
Vitamin E in Cod and other Fish-liver Oils : Occurrence of (Dr. F. Brown), 790
Vitamins in Metabolic Processes : The Role of (Nutrition Society Symposium on), 456
Vitreous Materials Internal Stresses caused by Disorder in (H. Rawson), 169
Volta River Aluminium Scheme, 330, 405
Volume Concentration of Stable Suspensions of Spherical Particles : Relationship between Relative Viscosity and (D. R. Oliver and Prof. Stacey G. Ward), 396
Vulnerability to Insecticides : Permeability of Insect Cuticle to Aqueous Stains and (S. Mukerji and S. N. Chatterjee), 119

WALES (North) · Hydro-electricity in, 332
Warburg Respirometer . Use of the, to study Microbial Activity in Soils (F. E. Chase and Dr. P. H. H. Gray), 491
Watches (Stop-) and Chronographs : Catalogue of (Camerer Cuss and Co.), 636
Water Absorption of, by the Egg of the Garden Chafer, *Phyllopertha horticola* L. (Roger Laughlin), 577
Lack of, in a Land of Water (Dr. G. F. Makkink), 19
Water (River) . Adsorption of DDT on Suspended Solids in, and its Role in Black-fly Control (F. J. H. Fredeen, A. P. Arnason and B. Berck), 700
Water Culture Methods used in the Study of Plant Nutrition : Sand and (Dr. E. J. Hewitt), review by Prof. R. H. Stoughton, 232
Water Problems in Dutch Agriculture, 19
Water-regimes . Effects of Different, on the Growth of Tomatoes under Glass (J. P. Hudson and P. J. Salter), 480
Water Retention in Cattle as a means of estimating Energy Exchange · Indirect Determination of (K. L. Blaxter and J. A. F. Rook), 609
Water Vapour Effects of, on the Electrical Properties of Anodized Aluminium (Dr. F. Ansbacher and Dr. A. C. Jason), 177
Water Vapour removed during Desiccation . Recovery of Caprinized and Lapinized Rinderpest Viruses from Condensed (A. L. C. Thorne), 609
Waters (African Inland) Sulphates in (R. S. A. Beauchamp), 769
Waters (Lake) · Occurrence of Hydroxylamine in, as an Intermediate in Bacterial Reduction of Nitrate (Motoharu Tanaka), 1160
Watt (James) International Medal for 1953 of the Institution of Mechanical Engineers awarded to Sir Harry Ricardo, 66
Wave Hypothesis of Moving Irregularities in the Ionosphere (C. O. Hines), 980
Wave-lengths between 4000 and 4600 A. · Multi-layer Dielectric Reflecting Films at (J. Ring and Dr. W. L. Wilcock), 648
Wave-lengths for Radial-Velocity Determinations of Stars (K. O. Wright), 637
Wave Mechanics Elements of (Prof. N. F. Mott), review by Prof. H. Jones, 409
Wave Mechanics for Beginners, review by Prof. H. Jones, 409
Weather Shore Life, Fish, Clouds and (H. Trevor Jones), review by T. H. H., 188
Weeds · Identification of Common, review by L. J. F. Brimble, 666
Weeds of the Major Crops of Ceylon : A Manual on the (Dr. J. C. Haigh and representatives of the Tea, Rubber and Coconut Research Institutes), review by Sir Edward Salisbury, 587
Weeds Illustrated Common Farm (Plant Protection, Ltd.), review by L. J. F. Brimble, 666
Welding and Fabrication : Summer School on (British Welding Research Association), 111
Wernher (Alexander Pigott) Memorial Travelling Fellowships in Ophthalmology and Otology (Medical Research Council), 111
West Indies (British) Meteorological Expedition to the, 419
Whales' Milk · Composition of (J. C. D. White), 612
White Clover (*Trifolium repens*) High in Lotaustralin Inhibition of Populations of *Haemonchus contortus* in Sheep fed on (J. H. Tetley), 311
Wild Life . Effects of Toxic Substances on, 820
Wild Life (British) . Impact of Man on, review by Dr. L. Harrison Matthews, 714
Wild Life of Britain . The Changing (H. L. Edlin), review by Dr. L. Harrison Matthews, 714
Wiles Lectures at Queen's University, Belfast, 1052
Wilkins Lecture for 1953 of the Royal Society (Sir Harold Hartley), 290
Wind Currents in the Sea : Measurement of, by the Method of Towe Electrodes (K. F. Bowden), 733
Wing-stroke Frequency of Insects . Flight-tone and (Dr. C. P. A. Pantin) 225
Winter Cascading from an Oceanic Island and its Biological Implication (Brian P. Boden and Elizabeth M. Kampa), 426
Wood (Alexander) Memorial Lecture for 1953 (Prof. C. A. Coulson), 77
Wood : Dry Rot in (K. St. G. Cartwright and Dr. W. P. K. Findlay), fift edition, 1053
Wood (Pencil) . Deodar as (M. A. Rehman and Jai Kishen), 732
Wood for Sectioning . A Method of Embedding Brittle Specimens c (J. P. Levy), 984
Woodlands in Scotland on January 31, 1953 : Storm Damage to (Prof. H. M Steven), 454
Wool : Apparent Degradation of, by Diazomethane Solutions (I. J. O'Don nell and Dr. J. M. Swan), 571
Wool Textile Engineering at Leeds, 460
Words (Scientific and Technical) . An Explaining and Pronouncing Dic tionary of (Dr. W. E. Flood and Dr. Michael West), review by W. L Sumner, 993
World · Economic Plants of the, review by Prof. Ronald Good, 898
World Congress on Fertility and Sterility First, 245
World Food Supply The Problem of Future (Nutrition Panel of the Foo Group of the Society of Chemical Industry Meeting on), 160
World Resources · Conservation of, 1
World-wide Changes in the Phase of the Cosmic-Ray Solar Daily Variati (T. Thambyahpillai and Dr. H. Elliot), 918

X-ORGAN of Crustacea (D. B. Carlisle and L. M. Passano), 1070
X-Ray Crystallographic Technology (André Guinier), English translatio by T. L. Tippell, edited by Prof. Kathleen Lonsdale, review by D W. A. Wooster, 586
X-Ray Crystallography . International Tables for, Vol. 1, Symmetry Group (edited by Norman F. M. Henry and Kathleen Lonsdale), review b Prof. P. P. Ewald, 944
X-Ray Diagram of the Cell Walls of the Marine Alga *Spongomorpha* Vari bility in the (E. Nicolai and Dr. R. D. Preston), 752
X-Ray Diffraction : Fortieth Anniversary of the Discovery of (J. Thewlis 106
X-Ray Diffraction of Bone : Low-Angle (Prof. A. Engstrom and J. Finean), 564
X-Ray Diffraction Study of the Transformation of Retained Austenite b Fracture (L. W. Pateman and H. S. Peiser), 696
X-Ray Evidence for Metal-to Metal Bonds in Cupric and Chromous Acetat (J. N. van Niekerk and R. F. L. Schoening), 36
X-Ray Inactivation of Polyploid *Saccharomyces* (W. H. Lucke and A Sarachek), 1014
X-Ray Micro-beam Technique : A Simple (L. C. Spark), 695
X-Ray Powder Diffraction Data . A.S.T.M. Index of (American Society fo Testing Materials), 155
X-Ray Therapy Travelling-Wave Linear Accelerator for (C. W. Miller), 297
X-Rays : 'After-effect' in Aqueous Solutions of Deoxyribonucleic Ac irradiated with (Malcolm Daniels, Dr. George Scholes and Di Joseph Weiss), 1153
Effect of Temperature on the Conductivity induced in Insulators (J. F. Fowler and Dr. F. T. Farmer), 1020
Therapeutic Action of Glutathione and Mercaptoethylamine against Lethal Dose of (Prof. J. H. Maisin, G. Lambert, M. Mandart and H Maisin), 971
X-Rays in Aqueous Systems : Formation of Labile Phosphate Esters by Irradiation of Nucleic Acids with (Dr. George Scholes and Dr Joseph Weiss), 920
X-Rays accompanying μ-Meson Capture (Columbia University 'Pres Release' on), 1097
Xylose in Jute · Association of Glucose, Arabinose and (Dr. D. B. Da M. K. Mitra and J. F. Wareham), 613

YEAST: Genetic Analyses of Intact Incomplete Asci of (E. A. Bevan) 576
Yeasts The, a Taxonomic Study (J. Lodder and N. J. W. Kreger-van Rij) review by Prof. Öjvind Winge, 989
Yellow (Indicator) . Rhodopsin and (Dr. F. D. Collins), 469
Yugoslavia : Nuclear Research in, 728

Z-ECHOES . Angle of Arrival of (G. R. Ellis), 258
Zanzibar Island : A Freshwater Eel on (Prof. J. L. B. Smith), 129
'Zero' Synthesis for Fourier Refinements (Andrew D. Booth), 168
Zinc : Kramer and Russell Effects with Single Crystals of (L. Grunberg ar Dr. K. H. R. Wright), 890, erratum, 914
Zodiacal Light . Photoelectric Observations of the (Prof. H. Siedentop A. Behr and H. Elsasser), 1066
Zoogeography, review by Charles Elton, 761
